#### 1. Introduction

During the last decades the design, construction and manufacture of wheeled vehicles has been almost wholly confined to capitalintensive motorised means of transportation. But the farmers, traders, private households and manufacturers in developing countries have to deal with simple and low cost transport. In other words appropriate technologies which are necessary for the development of economically weak regions have been neglected carelessly with the result, that all people involved in low cost transport either suffer in burdensome and inefficient transport, do not find labourintensive jobs or have difficulties to market their products.

This study tries to collect the relevant information on low cost, wheeled and non motorised transportation. In many cases the designs of available solutions were weak. Thus some improved constructions are demonstrated according to the standards of technical designing. Generally all designs are to be understood as recommendations which have to be adapted to the local transport needs and conditions, production capacities, raw materials and purchasing power.

## 2. Transport needs and criteria for the choice of appropriate solutions

The theory, actual situation and development of transport needs in developing countries have been discussed in the literature concerned (see chapter 5). Table 1 shows different means of transportation in connection with the local terrain, transport distances and groups involved.

In order to select different means of transportation according to the local transport needs and conditions, production capacities, raw materials, purchasing power and other technical, economical, environmental and social aspects it is recommended to proceed in two steps:

- Step 1 (general questions): What kind of transport is appropriate to
  - LOAD (kind, weight, dimensions, volume, durability, solidity, smell etc.)
  - <u>UNDERGROUND</u> (mountainous, hilly, plain, sort, hard, unprepared, prepared, metalled etc.)
  - COSTS (first investment, running costs, maintenance and repair, spareparts, depreciation etc.)
  - TRANSPORT RANGE (distance, time etc.)
- Step 2 (specific questions): What are the technical, economical, socioeconomical and environmental criteria and characteristics of available carriages with regard to
  - LOAD ASPECTS
    Kind of load (construction, hight, weight, flexibility of frame, platform, body, means of fixing)

Weight, dimensions, volume of load (dimensions, hight, weight, stability of frame, platform, body, kind of propulsion, wheels and suspension)

Durability, solidity of load (construction, flexibility of frame, platform, body, wheels and suspension)

#### - OPERATION ASPECTS

Transport efficiency (ratio of deadweight to payload)

Handling by operator (loading, unloading, simplicity and mobility of frame, platform, body, equipment, function of steering, brakes, propulsion and other devices)

Load flexibility (construction and equipment of platform, body and containers)

Driving comfort and security for operator, load and draught animal (kind, dimensions, weight, precision of carriage, wheels, brakes, suspension and other equipment, balance of body)

Frequency and range of transport (kind and size of platform, body, containers, wheels, suspension, brakes, propulsion, No. of wheels, max. speed, max. payload)

Maintenance and repair (stability, durability of whole carriage, simplicity, frequency and costs of m&r, availability of spareparts)

#### - PRODUCTION ASPECTS

Kind of local manufacture i.e. buildings, infrastructure, tools, equipment, labour force, raw materials, services etc. (technical standard, stability, durability, precision, price of whole carriage, kind of service, time of delivery)

Size of manufacture (technical standard, price)

#### - SOCIO-ECONOMIC ASPECTS

Kind of manufacture i.e. labour intensity, use of local labour and raw material, decentralisation (contribution to local development)

Size of manufacture i.e. small-scale (contribution to local development)

#### - ENVIRONMENT ASPECTS

Underground (construction, stability and flexibility of carriage, kind and size of wheels, brakes, suspension, propulsion, max. speed and payload)

Climate (kind and durability of carriage incl. platform, body and containers)

Ecology (emission of gases, dust, liquids, noise etc.)

Society (physical security of carriage for operator and other people, emission of gases, dust, liquids, noise, adequate stiling)

## 3. Description of technical solutions

## 3.1 Vehicle components

### 3.1.1 Wheels

Description: In order to transport loads beyond 50 kg weight which cannot be carried on human or animal back either disk wheels or spoke wheels are used. Generally wheels roll along the underground on the outer ring (rim) and rotate on an axle with the inner ring (hub) which is equipped with bearings. Both movements cause friction forces i.e. the rolling resistance (along the underground) and the bearing resistance (between hub and axle). These forces depend on the structure of underground, kind of rim and tyre, wheel width and diameter, bearing and axle width, diameter and material and the kind of lubricant.

As an example in figure 1 different frication forces of a hard wheel and a pneumatic tyre wheel on soft ground are shown, the first one having a 2.3 times higher resistance on the underground than the second (the bearing resistance is not

Fig.1: Friction forces on wheels

shown). If wheels with different rims (wood,

steel, pneumatic tyre, caterpillar) and the same kind of bearings (ball bearings) are compared systematically the rolling resistances demonstrated in figure 2 come out (performed by "Landmachineninstitut Berlin" 1933). Thus pneumatic tyres have an advantage if rolling on prepared roads but iron wheels should be favoured for transport on soft and wet underground. But the choise of appropriate wheels has to regard many other aspects such as the weight and kind of load, the riding comfort for load, driver and draught animal, the stability, durability and price of the wheel, range of road dammage allowed, capacity of

Fig.2:Rolling resistance of wheels on different terrain

is given in figure 3.

local manufacturers and others. A number of

technical solutions for these requirements

Fig. 3: Different kinds of wheels, old Persian wood wheel (a), old German wood wheel (b), Indian wood wheel with solid rubber tyre (c),

German-wood wheel with steel rim (d), iron spoke wheel (e), Indian iron spoke wheel with solid rubber tyre (f), pneumatic spoke wheel (g), pneumatic disc wheel with nylon hub (h)

From practical experience the following characteristics for the application of wheels can be derived:

- Wood wheels: high rolling resistance, transmit road shocks directly to vehicle, driver ,load and draught animal, high tare weight, medium dura= bility, carry loads up to 200 kg/wheel, big diameters favourable, iron tyres promote durability, solid rubber tyres absorb some shocks but can on= ly be used on prepared roads, manufacture is relatively simple and cheap.
- Iron wheels: high rolling resistance, transmit shocks directly, medium tare weight, good durability, carry loads up to 350 kg/wheel, big dia= meters favourable, on metalled roads solid rubber tyres recommended, manufacture needs modern tools, devices and some know how, medium price.
- Pneumatic tyre wheels: low rolling resistance on prepared and unprepared hard underground, shock absorbing effect, medium (disc wheels) or low tare weight (spoke wheels), good durability, carry loads up to 700 kg per wheel (5.50 16 " wheel) and more, medium diameters sufficient, good maintenance and repair necessary (assembling, adequate air pressure, renewal in time etc.), manufacture with good know how, relative ly high price.

As many problems for economically weak groups arise from transport on rough terrain it is recommended to manufacture simple, cheap but strong wood or iron wheels together with local wheelwrights. Thus the technical promotion has also positive socio-economic effects on the decentralised production which the large scale production of wheels with pneumatic tyres don't have:

In case of an actual demand for pneus the steel rim manufacturers must contact local tyre dealers in order to find out the diameters and widths of available tyres.

## 3.1.2 Bearings

<u>Description</u>: Bearings are necessary to support rotating shafts against a body or wheels against an axle. Generally two kinds of bearings are distinguished: friction and roller bearings. Table 2 gives some basic information on the characteristics of friction and roller bearings (hardwood, bronce, cast iron and ball-, cylinder-, needle-).

Table 2: Characteristics of friction and roller bearings

Criteria	Friction hardwood	bearings cast iron/alloy	Roller bearings
frictional resistance abrasion durability load capacity maintenance requirements local inputs technological status price	high high low low medium high low low	medium medium medium low/medium medium medium medium medium	low low high high low non high high

Friction bearings: For low speed and simple vehicles (less than lo miles/h) friction bearings in dry and halfwet version are common. The surface of the rotating shaft and the bush of the wheel have direct contact with some grease in between. This causes abrasion and heating of the bearing. Bushes made of hardwood and cast iron have a relatively low load capacity, the ratio length to diameter should be at least L/D = 3 (cast iron) to 4 (hardwood). Bushes made of alloys like bronce (copper with tin,lead,aluminium), white metal (lead, tin and antimony mainly) or aluminium alloy (aluminium with copper and zinc) resist to higher loads and are qualified for very low shaft speeds and shocks as well. Their ratio L/D ranges from 1 to 2. Each version should be greased regularly not only to reduce friction but to keep off dirt and sand. Additional washers made of leather, felt, rubber or iron might help to reduce abrasion.

Friction bearings in wet version are applicable only for high rotations. In this case a film of oil is between the metal of the bush and the shaft. The frictional resistance is accordingly low. Special washers and devices for constant oiling must be installed.

Roller bearings: They are valid for low and high speed vehicles as well. Bush and shaft are supported by balls, cylindrical rolls or needles between an inner and outer ring all made of refined steel. Due to their high precision production is limited to specialised firms. They build roller bearings suitable for all purposes. The ratio L/D is less than 1. Roller bearings run in grease if low speeds prevail and in oil at high rotations. Shocks should be prevented.

## Specification design 8

#### 3.1.3 Brakes

Description: The main brake systems are demonstrated in figure 5:

shoe brake shoe brake disk brake belt brake (one shoe outside) (two shoes inside)

a = drum, b = shoe, c = lining, d = cam, e = spring, f = belt, g = disk

Fig. 5: Main brake systems

Brakes must be installed in vehicles which are operated on slopes or which are driving with speeds higher than lo miles/hour. Concerning low cost vehicles it is recommended to provide

- handcarts with a total weight beyond 150 kg and operated at slopes with 10 % inclination and more
- animal drawn carts with a total weight beyond 250 kg and operated at slopes with lo % inclination and more
- tractor drawn carts and trailers with a total weight beyond 500 kg and speeds higher than lo miles/hour
- all kinds of cycles
- all kinds of motorised vehicles

with adequate brakes.

The capacity of shoe brakes has to be calculated with the equation  $F_{\,f}\,=\,F_{\,s}\,\times\,\mu\,\,>\,F_{\,p}$  with

F = force of friction at the drum

F = brake force at the shoe

 $F_{p}$  = periphery force at the drum (or wheel)

 $\mu$  = coefficient of friction

For brake shoes made from cast iron  $\mu$  = 0.15 " " " hardwood  $\mu$  = 0.25 For special brake lining (ferodofibre)  $\mu$  = 0.40 Figure 6 shows systematically the action and reaction of the different forces at the shoe brake

Fig.6: Forces at the shoe brake

The capacity of belt brakes has to be calculated according the formula  $F_f = F_b \times (m-1) > F_p$ 

with

 $F_f$  = force of friction at the drum

 $F_b = brake$  force at the belt (in direction of  $F_b$ )

 $F_{p}$  = periphery force at the drum

m = coefficient depending on a and /4

≃ = enclosing angle belt-drum

 $\mu$  = coefficient of friction (see above)

Some data on m are given below

oc.	$\mathcal{M}$				
	0.1	0.2	0.25	o.3	0.4
180°	1.3	1.8	2.2	2.5	3.5
225°	1.5	2.2	2.7	3.3	4.8
270 <sup>0</sup>	1.6	2.6	3.2	4.1	6.6

Fig. 7: Forces at the belt brake

The periphery force  $\mathbf{F}_{\mathbf{p}}$  at the drum must be calculated from the forces at the wheel resulting from retardation of the fully loaded vehicle at a horizontal or inclined road. The necessary brake force  $\mathbf{F}_{\mathbf{b}}$  can be derived from hand or foot operated levers (max. manual force 25 kg) via transmission levers or wires to the brake. As regards belt brakes it is important to mention that  $\mathbf{F}_{\mathbf{b}}$  must pull in direction of  $\mathbf{F}_{\mathbf{D}}$  i.e. with the rotating wheel.

For low cost vehicles simple shoe brakes from hardwood or belt brakes with steel belts and leather lining are common. Double shoe brakes with two shoes outside or inside the drum and disk brakes are more efficient and cause only little opposing forces at the bearings of wheels and axles. But their manu= facture needs fair workshop equipment and know how. They are more expensive than the simple shoe brake.

The following design 12 demonstrates a shoe brake of a 2-wheel ox cart wor= king directly at the wheel (source: TAMTU, Tanzania, DSE/ZGB, FRG).

## Specification design 12

Part No	Part name	Material	Dimensions of raw material

10	axle	MS round steel	
11	wneel	MS	

#### 3.2 Non motorised vehicles

#### 3.2.1 Pedal driven vehicles

Main characteristics: Pedal driven vehicles are either 2-wheel (bicycles) or 3-wheel vehicles (tricycles). The wheels typically have a diameter of 28" or 710 mm. Transport by bicycle is about four times as efficient as walking. Its most popular type has a deadweight of about 30 kg and is mainly used to transport one person i.e. the driver himself. As the two wheels roll in one track the bicycle is qualified for paved and unpaved roads and narrow foot= paths as well. Payloads up to 150 kg can easily be carried if adequate plat= forms or containers are fixed to the bicycleframe. In order to obtain stable driving conditions and a higher transport capacity the tricycle was construc= ted. Most widely used in Asia it allowes to carry two or three passengers and even bulky cargo up to 250 kg. Its deadweight ranges between 40 and 80 kg and its track is more than 1 m. Thus its application depends on prepared and sur= faced roads with enough width.

Construction and operation: The standard cycles which at present predominate in developing countries for transport of passengers and cargo are, by comparison, old fashioned. Their heavy frames are joined by lugs which are produced with highly mechanised methods in medium scale industries or imported. To meet the conditions of local small scale production and the specific transport needs some improved cycles have been designed. In figure 8 some conventional and improved cycles are illustrated.

For bicycles besides passenger transport different kind of carriers are used to move cargo: wood containers, steel hoops to insert water tanks, wicker panniers, steel platforms etc. In most cases these devices are fixed on both sides of the rear wheel to the frame (e.g. in China) but there are also sturdy containers to be found directly over the front wheel (e.g. in Europ or USA). In Tanzania a bicycle transporter has been developed where two platforms welleded from anglebars are fixed to the conventional frame on both sides and a front carrier over the front wheel of the bicycle. Thus it is possible to push 150 to 200 kg load on narrow tracks while walking on the left side of the vehicle. Efficient operation is gained by a special pushbar, a broad steering bar and handbrakes on each of these bars (see design 12).

The widespread use of tricycles especially in Asian cities reveals a real need for low cost transportation. Nevertheless the existing designs cannot be regareded as satisfactory. Mostly rickshaws with passenger bodywork have to deal not only with persons but with bulky or loose cargo too which does not fit to the body construction. Besides this the vehicles are too heavy, the single-speed transmission imposes undue strain to the rider and brake systems are not valid for the existing traffic situation.

Answering to these disadvantages the socalled "Oxtrike" was constucted. It is light (40 kg), has a three-speed gearbox and foot-operated inboard band brakes in addition to the front handbrake. The chassis makes use of sheet steel which is cut, folded and welded without the use of expensive machinery. Furtheron the 20" diameter wheels of the Oxtrike give a longer load platform which can be provided with containers, tanks or passenger seats. While the Oxtrike is suited only for transport on prepared roads there is still a need for an improved tricycle on rough terrain. It is recommended to promote the constuction of common tricycles according to the criteria mentioned above.

#### 3.2.2 Wheelbarrows and handcarts

Main characteristics: Wheelbarrows and handcarts have one to four wheels and one or two handles to push or draw the vehicle by hand. The most common wheel=barrow has one wheel, two handles and a small load container in between.

All kinds of private, commercial and public sectors use wheelbarrows and hand=carts to transport agricultural products, fertiliser, soil, stones building material etc.(high load flexibility). The maximum payload of wheelbarrows is relatively low (for standard types up to loo kg, for improved versions up to 150 kg). The operator has to carry part of the load himself and must keep the vehicle in balance while driving. On the other hand wheelbarrows are very handy and qualified to roll on narrow and uneven footpaths and rough terrain. The max. payload of handcarts is generally higher. All vehicles of this kind have a small transport range and are not suitable for use in steep gradients.

Construction and operation: As wheelbarrows and handcarts are mainly operated by one person and sometimes off road their construction should fulfil some basic requirements:

- low centre of gravity (with regard to balanced driving)
- low rolling resistance
- low burden for the carrying person
- simple, cheap and strong design

The technical solution of these and other requirements meets some difficulties e.g. a low rolling resistance calls for big wheels which is in contradiction to a low centre of gravity. In adapting the technical possibilities to spe= cial transport demands a large variety of wheelbarrows and handcarts has been developed (see figure 9). From there it can be seen that wheelbarrows are either made from wooden or structural steel parts. Steel carriages, if manufactured properly, are generally lighter than those made of wood. Dependent on the kind of load flat or open, box-type or partly closed load platforms and containers are used. Appropriate wheels must be selected according to road surface, load, driving comfort, production capacity of wheelwrights, purchasing power of users etc. (further details on wheels see chapter "wheels").

If loads beyond lookg are to be transported modified wheelbarrows with the wheel directly under the platform or handcarts must be introduced. In this case the load is placed close to the wheels axle and the operator only has to support a small proportion of the load. Thus more of his energy can be devoted to propelling the vehicle forward. He wears a strap which passes across his shoulders and is attached to the handles of the barrow. Loads beyond 150 kg should be handled by handcarts or cycles.

A very special type of wheelbarrow has been developed in Korea. Its design was derived from the traditional backpack called "chee-ke" which is used by porters to carry loads up to 60 kg in hilly areas. In order to reduce the

Fig. 9: Different kinds of wheel=

barrows and handcarts, Chinese barrow (a,e), German stave-, platformand box-wheelbarrow (b,c,d), sack-barrow (h), 2-wheel handcarts (f,j,1)
bicycle trailer (g), 4-wheel handcarts (i,k)

physical effort required by the porter the chee-ke has been equipped with two pneumatic tyre wheels (see figure 10). Instead of the traditional wood frame a steel pipe frame was designed. Thus heavy loads can be carried either on human back along hilly terrain or rolled on even roads. As this construction has a deadweight of 12 kg or more a lighter version is shown in this study (compare design 18). Its frame is manufactured from aluminium pipes and it has only one wheel. Thus a deadweight of about 4 kg comes out. This construction has to be adapted and improved locally.

Fig. lo: The improved backpack device "chee-ke" from Korea

Remark: While carrying the chee-ke on human back the handles (13) are to be used to balance and support the load. When changing the chee-ke to the wheelbarrow function the handles can be used as a set down support (handle position a) and as driving handles (position b).

### 3.2.3 Animal drawn carts

Main characteristics: Animal drawn carts with two or four wheels are the major form of rural transport in many developing countries. Their transport efficiency depends on the condition of the cart, harness and draught animal. Provided that the animals are well tamed and trained they develop an average traction power of 250 (donkeys), 400 (mules), 500 (cows), 700 (buffaloes), 750 (bullocks) and 800 kg (horses). Thus it is enough to employ one animal for small carts on flat and prepared underground but two animals and more for bigger carts and rough conditions. The power of animals is frequently reduced as carts are badly balanced and a heavy burden presses the yoke on its neck. Besides this many yokes are inadequately shaped, too hard or wrongly situ= ated.

The most common cart has two wheels, a flat and open platform and a long shaft to harness one draught animal. It is applicable for road and off road transport (high terrain flexibility) and has a turning circle not more than the total length of the cart. The max. payload of the 2-wheel type ranges between 0.4 tons (donkey cart with wood wheels) and 1.5 tons (bullock cart with pneus). Normally volumes close to 2 cubicmeters can be carried. The efficiency ratio (deadweight:payload) ranges between 1 : 1.5 (traditional wood construction) and 1 : 2.5 (advanced steel construction).2-wheel carts must be balanced by the animal (low driving stability).

The 4-wheel cart is drawn mainly by two animals on fair roads or plain underground. If operated on uneven terrain the frame and platform of the 4-wheel cart is stressed by extreme forces due to torsion. They are suitable for loads up to 3 tons (two bullocks and pneumatic tyres) and volumes between 3 (container loaded with loose and heavy cargo to its upper brim) and 12 cubicmeters (load container with frame for hay). Traditional types have an efficiency ratio of 1: 1.5, advanced steel constructions about 1: 4. Its turning circle ranges between 6 m (cart with swivelling bolster steering) and 9 m (cart with axle pivot steering).

Generally animal drawn carts are used for long distance transport for all kinds of load. For each transport demand it must be decided whether flat or curved, open or closed, fixed or tipper-type load containers, wood, iron or pneumatic wheels, suspensions or brakes are adequate or not. Existing carts often use the animal power very inefficiently as they are too heavy loaded, badly balanced (so that a significant part of the load bears down on the neck of the animal), equipped with rough yokes and harness and carelessly maintained.

Construction and operation: Commonly there are used four types of <a href="https://examples.com/harnes

Apart from the task to improve existing harness (suffering animals have no efficient tractive power) it is necessary to consider the common types of carts with regard to

- adequate mechanical and driving stability
- low rolling resistance
- good loading/unloading and transport performance
- high load and road flexibility
- high driving security and comfort
- simple, cheap and strong design

Because of these factors and the range of conditions under which animal carts are manufactured and operated the need is for a number of different constructions. Figure 12 shows some existing types with wide diffusion.

For relatively small farmers and traders the 2-wheel cart seems to be favour= able. Even if employed on uneven terrain no major torsion forces appear at the frame of the carriage. Significant forces occur near the axle support as vertical movements of the wheels are transmitted directly to the platform. The mechanical structure of 2-wheel carts allowes relatively simple details. Special attention must be given to the design of the shaft, yoke and harness as well as equal distribution of load and the position of the axle under the platform (less than 55 % of the load in front, 45 % behind the axle). An appropriate construction of 4-wheel carts must be based on the following technical details. In order to obtain a high efficiency ratio the carriage must be light but strong. Though wooden carts generally are more heavy than steel carts it is possible to produce efficient wood vehicles which fulfil the requirements of uneven terrain. One of the axles must be attached to the frame by a flexible joint in order to keep peak torsion forces off the body. The same result can be obtained by wheel suspensions which is obviously more expensive. During the last years carts welded or srewed together from struc= tural steelparts have proved true. They are more costly than wood carts of the same type but their tare weight, stability and durability are favourable. Since the introduction of pneumatic tyre wheels the diffusion of steel carts increased rapidly.

Fig.11: Various types of harness, double yoke for oxen (a,b) and with pads and collars for horses (c,i), single neck yoke (d) and head yoke (e), collar harness for cattle (f,g) and horses (h,i), swingletrees for one and two animals (k) (source: FAO Agricultural Development Paper No. 91)

To prevent early tearing of vehicles while operating on uneven terrain (see fig. 13) rather flexible constructions have been developed. Body and frame are exposed to peak for ces especially along the cornerpieces where longitudinal and crossbeams are connected. Figure 14 shows an example of a frame under torsion with a

Fig.13: Scheme of a flexible and an unflexible coach on groundwaves

a frame under torsion with a swivelling bolster steering and U-pro=file beams. It has two longitudinal beams which give a medium flexibility to the frame. The two diagonal cross=beams at the front part give a firm structure. More flexible are frames with one central beam. A comparison between the different frames and the respective crosspieces is given in figure 15. It has to be mentioned that in connection with central beam frames only the axle pivot steering should be applied.

Fig.14: Cart frame from steel, infle=
xible front part to guarantee
easy steering and flexible rear
part

Fig.15: 2-beam and 1-beam frames, cornerpieces and different kind of central beams

connection axle - wheel support

Fig.16: Different kinds of cornerpieces and connections between beam, axle

and wheel support, welding connection is wrong (a,b,c), better (d,e)
and good (f,g)

In order to produce strong cart frames in figure 16 some details on the kind of welded connections are recommended. Solutions a,b,c are wrong, those of d,e are better and solutions f,g are good. Frames assembled with screws must ful= fil the same principles. In particular the strength of frames is determined by its design and the quality of raw material. Only little is contributed by the thickness of the material used.

Concerning the <u>steering</u> of 4-wheel carts two systems must be distinguished: the swivelling bolster steering and the axle pivot steering (see figure 17). The swivelling bolster steering allows narrow turning circles (about 6m), it is heavy, strong and cheap. In narrow curves its standing stability is highly reduced which gets quite dangerous on inclining terrain. Horizontal forces from the road are directly transmitted from the wheels to the shaft and harm the draught animal. This can be diminished by using pneumatic tyre wheels.

## Fig.17: Axle pivot steering (left) and swivelling bolster steering (right)

Carts with axle pivot steering have a wider turning circle (about 9 m) but their standing stability is not reduced while riding through narrow curves. Shocks at the wheels don't come directly to the shaft and the neck of the draught animal. The axle pivot steering is relatively light but expensive and sensitive against twisting. Practical solutions of each steering system

Fig. 18: Axle pivot steering (left) and swivelling bolster steering (right)

With regard to an enhanced driving safety <u>brakes</u> must be installed in carts operating at inclining roads or/and with speeds beyond lo miles/hour. Many bad accidents have occured already as heavy carts were not equipped with adequate brakes (compare chapter "brakes"). The brakes can be set into func= tion by foot- or handpedals. If the driver walks mainly aside the cart a handlever should be installed on this side. If he is sitting the most time on the coachseat either foot- or handoperated levers must be in front of the cart. When riding a tractor a handlever must be installed at the shaft (see figure 13).

Fig. 19: Different kinds of brake lever installations in carts

Animal drawn carts riding with low speed do not need a suspension bet= ween wheels and body. But if the load is sensitive and must be pro= tected against shocks or if extremely rough terrain will reduce the life= span of the cart it is recommended to fit the vehicle with prefabricated leaf springs. This makes the cart more expensive and reduces its stan= ding stability on inclining slopes. Figure 20 gives an example of a leaf spring and its installation in the front part of an animal drawn 4-wheel cart.

Fig. 20: Leaf spring and installation

The choice of appropriate wheels for carts influences its all over efficiency. E. g. the rolling resistance of hard wheels is about 50% higher than that of pneus. On rough terrain the difference is less or zero (see chapter "wheels"). It is recommended to continue the use of hard wheels for transport on unpre=pared terrain with low speeds while giving priority to big diameters. Some remarks on standardisation might be quite helpful: Typical for on-farm carts in Europe is the standard track (1.25 and 1.5 m). Other standards deal with the dimensions of the platform (e.g. 2-ton cart: length 3.5 m, width 1.6 m, height above ground 1 m), the max. payload (2,3,4,5 tons) and the size of rims and tyres (e.g. 5.50-16 or 6.00-16). Experience shows that the plat=form height of 1 m above ground is a good compromise for comfortable loading, unloading, adequate standing and driving stability and wheel size. These standards have proved to facilitate the work of designers, producers and users of vehicles.

### 4. Workshop equipment for the manufacture of low cost vehicles and components

The vehicles and components described in the chapters before are constructed for small scale manufacture, i.e.

- application of basic and relatively cheap workshop tools, devices, machinery and other equipment
- low cost investment, working capital and infrastructure
- occupation of local labourers
- use of a high proportion of local raw material
- labour-intensive and decentralised manufacture

As the vehicles shown before have a different technological standard the fol= lowing recommendations distinguish between

- manufacture type a : basic woodworking
- manufacture type b : advanced woodworking
- manufacture type c : basic metalworking
- manufacture type d : advanced metalworking

Regarding raw materials it is important to use

- dry wood (either stored under a roof for several months or dried in a special drying device)
- oil impregnated hardwood for friction bearings
- varnish after finishing wooden structures (in order to protect them against damage by moisture, rain etc.)
- strong screws instead of nails for assembling the wood parts
- <u>structural steel profiles</u> (sheet metal, flat steel, round bars, pipes, L-, T-, U-profiles etc.)

### Type a: Basic woodworking equipment

- work bench (wood, 800 mm high, 650 wide, 2500 long, strong and accurate)
- woodworking vice (wood or cast iron)
- sawing horses (wood)
- crosscut handsaw (700 mm blade)
- compass saw (300 mm blade)
- claw hammer (o.5 to 1.0 kg)
- wood rasp (flat and half round blades, about 400 mm long)
- carpenters ratchet brace with auger bits (3, 5, 10, 15 mm)
- screw driver (250 mm long, 5 mm wide blade)
- open ended spanners (lo, 13, 17 mm width)
- measuring tape (2 meters long)
- set square (400 mm)

#### Type b : Advanced woodworking equipment

like type a and in addition

- tenon saw (300 mm blade)
- wood files (flat, second cut; half round, second cut; 300 mm long)
- pincers (150 mm long)
- chisels (bevel-edged, square-edged, mortise chisel)
- wooden mallet
- jack plane (either wood or metal, 400 mm long)
- G-cramps (150 and 300 mm)
- spokes shave
- hand drill with set of bits (3, 5, 10 mm)
- expanding bits (15 to 30 mm)
- different kinds of assembling jigs (self made)
- hand or foot operated turning lathe for woodworking

### Type c : Basic metalworking equipment

- work bench (wood or steel, 800 mm high, 650 wide, 2500 long, strong)
- metalworking vice (cast iron)
- standard hacksaw (300 mm blade)
- ball pein hammer (o.5 kg)
- files (flat, second cut; half round, bastard; 250 mm long)
- breast drill with set of bits (2,3,4,6,8,10 mm)
- screw driver (250 mm long, 5 mm wide blade)
- combination pliers (200 mm long)
- set of open ended spanners (7 to 24 mm width)
- centre punch
- measuring tape (2 meters long)
- engineers scriber and divider
- set square (300 mm)
- rim bending and wheel assembling jig
- welding apparatus

### Type d : Advanced metalworking equipment

like type c and in addition

- wire frame hacksaw
- copper hammer (o.5 kg)
- files (flat, smooth; round, second cut; 250 mm long)
- hand operated post drill (with 12 mm capacity chuck)
- tin snip(straight blade 200 mm)
- adjustable spanner
- die stock and set of taps and dies (for 6 to 12 mm threads)
- simple bar and pipe bending equipment
- sheet metal folder and guillotine (250 mm long blades)
