PREFACE.

Another year has been added to our labours, and it is again a pleasant duty to lay before our readers a brief account of the progress of the two professions, to the service of which we are devoted. It will naturally be expected that in a year of severe financial embarrassment, succeeding also to one so fertile in important results as was the last, there must necessarily be a falling off in the amount of what would otherwise have been effected, and a delay in the execution of many works, the completion of which is thereby retarded. Our own exertions, however, we have not suffered to flag under circumstances so dispiriting, but trust that so far as has depended on us, the present volume is worthy of its predecessor, and of the patronage with which our endeavours have been crowned.

In considering the general features of architecture, we find that the invasion of the Renaissance style, which we announced last year, has actually occurred, but has singularly been accompanied with, or rather smothered by, a resuscitated taste for Elizabethan external and internal decoration. Considerable attention has also been devoted to the early antiquities of Moresque architecture. Our own ecclesiastical antiquities, we are happy to mention with praise, have been chosen as the special object of enquiry by a Society of Clergymen at Oxford, and thus we are led to hope for an improvement in taste, in a quarter which hitherto has had but too great a part in producing the present degeneracy.

A striking and interesting circumstance to every well wisher of the arts, is the great zeal with which both associated bodies and individual members of the profession have engaged in the struggle for maintaining the true principles of competition. Among these cases have been the Nelson Testimonial, St. George's Hall Liverpool, and the Royal Exchange, in the still pending contest respecting which latter, we believe we may say with truth, "Quorum pars maxuma fui." On learning the extraordinary attempt to impose a tax of a guinea on applicants, for copies of the Instructions of the Committee, we immediately obtained copies both of the instructions and the plans, and left them at our office for the free use of any applicant—a course of conduct for which we feel an abundant reward, in the vote of thanks unanimously bestowed on us by the Manchester Architectural Society. From these exertions hitherto, no immediate fruit has resulted, but much has been already attained from the influence which they have had in awakening the public mind from its lethargy, and calling its power to a subject so importantly affecting the national glory and the general taste.

Great progress has been made this year in bringing the accessary science of geology to bear upon architectural pursuits, and with a success which must have an influence on the future progress of each respectively. Government issued a commission, composed of geologists and architects, to examine the quarries of England, for the purpose of ascertaining the stone best fitted for the construction of the new Houses of Parliament. This commission has produced a report which must long be a standard of information to the profession, and a valuable model in future enquiries. The Goverment has also formed a Museum of Economic Geology, attached to the department of Woods and Forests, in which the commissioners specimens are collected, and to which future accessions will be made. Special courses of lectures on the connection of these two subjects have been delivered by eminent geologists: at the Royal Institute of British Architects by G. F. Richardson, (reported in our Journal), and at the Architectural Society, by E. W. Brayley, jun. Great attention is also paid to these subjects in the several faculties of civil engineering. Although not yet brought into immediate connection with architecture, we feel it our duty to allude to the discoveries in photograpy by Daguerre and Fox Talbot, and to those in engraving by voltaic electricity made at Liverpool. In the British Museum great improvements have been effected, and a Museum of Antiquities has been formed by the city authorities, in Guildhall. We regret, however, that the Soane Museum, the proper Museum of Architecture, as yet manifests no progress. The elementary drawing and professional schools throughout the country have exhibited a remarkable improvement, as have the schools of design, and the class of decorative artists appears to have attained a higher standard than it ever before reached. An act has been passed for giving protection to the copyright of manufacturing designs, and it is to be hoped that this symptom of a better system of legislation for art, may be pursued successfully. We may mention here as another legislative act, although not in perfect regularity, that an amendment has been made in the Brick Duties Act.

Great numbers of churches have this year been erected, and more are in progress, but of works of a high class few have been completed. We may however mention the Reform Club; the Club Chambers Association; the Athenæum and Unitarian Chapel, Manchester; the Highgate Cemetery; a Conservatory at Chatsworth for the Duke of Devonshire, one of the largest in the world; and a Colossal Monument in Scotland, to the Duke of Gordon. Many elegant commercial buildings have been erected; and an increased taste has manifested itself for public gardens, cemeteries, and other branches of landscape gardening. It is with regret that we are still obliged to complain of the little regard that is paid to the maintenanoe of the public taste, by the managers of the funds for the new churches. As to the other arts they are totally neglected, and architects have generally to complain of the niggardliness and inefficiency of the means placed at their disposal. In fact the advocates for new churches, like the fitters out of emigrant ships, seem to think that plenty of stowage is of much more importance than either convenience or safety. The members of the establishment have a rich inheritance of artistical wealth left to them by our ancestors, and they are morally bound to maintain its dignity, yet so far from doing so, they make little provision for the future, and take little care for the preservation of what they have in hand. We have to regret this year the demolition from such neglect of the nave of St. Saviour's, Southwark, a shrine rich in its antiquarian and historical associations, and the injury by a most terrific hurricane in the early part of the year of the Cathedrals of York, Chester, and St. Patrick's Dublin, and of the Town Hall, Birmingham, and subsequently of the Cathedral of Ripon. Repairs and restorations have been effected of Wolverhampton, Collegiate Church, Madley Church, the Pilgrim's Chapel Maidstone, St. Mary's Redcliffe, the east end of Guildhall, and many of our Cathedrals. A Government grant has been made for the restoration of the Cathedral of Glasgow, a work meritorious in itself, but an act of local favouritism, which has been vainly solicited for other parts of the empire. But a small grant would have preserved St. Saviours. Some slight improvements have been made in Whitehall, but no measure has been taken to render more worthy of the public a line of communication which possesses many interesting monuments, and recalls many historical scenes. The palaces of Whitehall and Northumberland House, both have a back view upon this site, and here also are situated the statue of James 2d, the United Service Museum, and the Water Gate. The principal foreign edifice completed this year, has been the Winter Palace of St. Petersburg, a work of great splendour and of rapid execution, a wonder of power if it were not an emblem of the weakness of the Russian empire. While this monument of selfish barbarism has been erected, what has been done for the temporary and permanent welfare of that immense realm? Canals have been projected a hundred years, and the only railway is that leading to the palace.

We have to deplore the loss of two members of the profession, each of whom has left a name, which must long live in its history. William Wilkins was the architect of Downing and University Colleges, of the University Club, St. George's Hospital, and the National Gallery; Rudolph Cabanel most distinguished himself as a theatrical architect, and by the improvements he introduced in many of the technical branches of architecture. Mr. Hardwicke has succeeded Wilkins as a Member of the Royal Academy, and Mr. Charles Cockerell as Professor of Architecture. Architects have as usual been lax in the literary career, but many valuable works have been produced, among which we may mention the new edition of the Public Buildings of London, by W. H. Leeds; the Public Buildings of the West of England, by John Foulston; the Traveller's Club, by W. H. Leeds; the Ancient Half-timbered Houses of England, by M. Habershon; the Suburban Gardener, by J. O. Loudon; the Architectural Remains of the Reigns of Elizabeth and James 1st, by C. J. Richardson; and the new edition of Repton's Landscape Gardening, by J. O. Loudon.

When we come to contemplate the government measures affecting the engineering interest, we are at once struck by a combination of jobbery, such as no year has hitherto so abundantly produced. Defeated in the House of Commons on the Irish Railway business, they managed to perpetrate the Shannon Navigation job; and again repulsed by the public voice on the Steam Vessels Accidents Commission, hydra-like they bring out a new report on Railways, teeming with all the elements of fertile mischief, at the very period when their own officers had exposed in the case of the Caledonian Canal, the consummated evils of a long process of ignorance and mismanagement. One of their last acts has been the appointment of a commission, to investigate the Harbours on the south coast of England, and another to decide on the competing railway lines to Scotland and Ireland. The results of these two measures the experience of their predecessors has taught us to look to with dread, and we have little hope from their origin of any error in our prognostic. It is to us a matter of consolation that we have not been remiss in opposing so far as in us lay, measures so fraught with iniquity, and we believe we may say with some little effect, but it depends neither on our temporary exertions, nor on those of others to combat this growing evil, it requires the united energy of every person interested, to resist a series of measures which are confined to no party and to no set of men, but are part of a system taken up with the robes of office and uniformly pursued by the most opposite in opinion. The civil engineers have an immediate interest in exerting themselves for this object, as the certain result of government success in this system must be to reduce the members of the profession here as abroad, to be the liveried sycophants of the government, instead of the independent officers of the public at large. To resist these attempts on the part of the government authorities, a Railway Society has been formed, although, we believe, not conducted with the spirit necessary to ensure success.

A circumstance greatly affecting the mechanical members of the profession, is the great development given to public taste for subjects, by the successful results of the Leeds and other Mechanics' Exhibitions. Some experiments, interesting to the profession generally, have been made on the explosion of mines, and charges of powder under water by voltaic electricity.

The agitation in the early part of the year respecting the Great Western Railway enquiry, subsided on the decision of the proprietors of that undertaking, to continue the plans of Mr. Brunel. The second Report of the Committee on Railways is only valuable from its statistical facts, which show indisputably the necessity for lowering the present high fares. Above one hundred and fifty miles of railway have this year been opened, of which the London and Croydon, and Aylesbury branch have been opened throughout, and the following partially, the Eastern Counties to Romford; the York and North Midland from York, to the Leeds and Selby Railway; the Southampton from Hartley Row to Basingstoke, and from Winchester to Southampton; the Great Western from Maidenhead to Twyford; the Manchester and Leeds, from Manchester to Littleborough; Birmingham and Derby; Midland Counties; and Glasgow, Paisley and Ayr, from Ayr to Irvine. The system of galvanic telegraphs on the Great Western Railway, established by Professor Wheatstone, has completely succeeded. Several foreign railways have been opened, among which are the Versailles, Amsterdam and Utrecht, Taunus, and Emperor Ferdinand's from Vienna to Brunn. For ordinary roads active exertions are now being made to introduce wood pavements.

We have already mentioned that a commission has been directed, to examine the harbours between the Thames and Portsmouth, and we may farther state that the hydraulic department of engineering has this year effected many important improvements, and shows an energy which promises much more. The works in the Wash are continued with success, and active measures have been taken for the improvement of the north west coast. The Mersey, Ribble and Wyre have been deepened, and important plans are in agitation for effecting the remaining objects. After many suggestions from different quarters, actual experiments have at last been made on the propelling of vessels on canals by locomotive engines on the banks, and with such success as to leave little doubt of the permanent establishment of this mode of transit. Experiments have also been made on the use of steam vessels on canals. At Cardiff, extensive docks have been formed at the expense of the Marquis of Bute. One of the finest hydraulic works of the year, has been the river wall for the new Houses of Parliament. In France much attention has been directed towards the improvement of their harbours, and a preliminary grant of nearly two millions sterling has been made for this purpose.

Steam navigation maintains the interest which it excited last year, and has received many important accessions.—A vigorous attempt has been made by government to establish over it a spy and job system, but it is to be hoped that the miserably trifling results of their intrigues, will induce them to give up this barefaced attack; no exertion must however be omitted by all parties steadily to resist the obnoxious measure. The utility of iron steam vessels seems to have been fully established, and they have been most extensively used, particularly for river navigation.—Many also have been sent to distant parts of the empire, and to foreign countries. Their success has led to the employment of iron as a general material for ship building, and the example of the Ironsides has been followed by the building of many other iron sailing vessels. The experiments on the Archimedes and other vessels have been continued, but have led to no permanent results, the French steamer Veloce was unfortunately burned, but a sailing vessel called the Vernon, is making a voyage to the East Indies, provided with a new kind of propeller. Professor Jacobi has made some experiments on the Neva, with a boat propelled by electric apparatus, but these like the previous attempts of the Americans have been hitherto inefficient. The steam navy has been greatly increased, and the dockyards improved, at Woolwich a central establishment has been formed. Among the vessels launched are the Cyclops (the largest steam frigate in the world), the Hecla, the Stromboli, and the Prometheus. For the East Indian navy have been built the Sesostris and the Queen. The adoption of large hollow shot as an armament for this class of shipping has greatly increased its efficiency. Sweden, Russia, and Holland, are among the foreign powers who have shown attention to their steam navy, to which our English vessels have served as models. Transatlantic steam navigation has been increased by the accession of the British Queen steamer, and government has entered into a contract for the conveyance of the mails by steam from Liverpool to Halifax, Boston and Quebec. The company for steam navigation to India by the Cape, has been discontinued, and their large class steamer sold; for the line by the Red Sea, however, the East India merchants have raised a hundred thousand pounds. Dunkirk and Rotterdam may be mentioned as rising steam ports, and Hull has by this mode of communication, successfully increased her eastland trade. The French have made their steam voyages to Russia productive of great commercial advantages in the sale of articles of luxury, and they have greatly extended their steam commercial marine.

Engineering literature has been increased by the production of many valuable works, most of which, even in the present progressing age of science, must remain standard works in the library. The mental labours of the profession have not indeed been of less importance than those in the field, and as great care has been shown to leave our successors good instructions as good examples. We may enumerate: Sections of English Railways, by George Bradshaw; the London and Birmingham Railway, by Thomas Roscoe and Peter Lecount; Illustrations of Mechanics, by the Rev. T. Moseley; the Practical Treatise on Bridge Building, by E. Cresy; on Steam Boilers, by Josiah Parkes; the Theory, Practice and Architecture of Bridges, by James Hann and William Hosking; On Oblique Bridges, by George Buck; On Arithmetical Perspective, by C. E. Bernard; On Steam Engine Boilers, by R. Armstrong; On the Construction and Formation of Railways, by James Day; and on the Construction of Oblique Arches, by John Hart.

The faculties of Civil Engineering, established in different Universities during the last year have gone on with success, and that at King's College, London, has particularly distinguished itself by improvements in instruction, and by the zeal of its professors. The University of London has announced its intention of granting diplomas for attainments in Civil Engineering, but on what basis they proceed we have not yet been able to learn. If the previous course required for this be similar to that required for their other degrees, it may be very difficult, and very useless; an engineer would rather have in his employment a working man than a college diplomatist. Attempts are now being made to establish a College for Civil Engineers, which it is to be hoped may be conducted on such principles as to render it useful.

A monument to Telford, has been completed, and placed in Westminster Abbey, and a handsome testimonial has been presented to a living engineer, Robert Stephenson, for whom also a statue is contemplated. Biographies and memoirs have been published of Watt, Telford, Trevithick, and James.

The proceedings of the several professional societies, this year, have been such as to maintain their previous high reputation. The several architectural bodies, the Royal Institute, the Architectural Society, and that at Manchester have applied themselves with vigour to obtain a fair system of competition, and have shown every attention to the improvement of their members, by courses of lectures on the collateral sciences, and by the distribution of prizes. The Royal Institute of British Architects has conferred a testimony of esteem on one of its officers, Thomas Leverton Donaldson, whose services have been long and publicly known. To the Manchester Architectural Society we feel indebted for a tribute of praise to which we have already referred. In Ireland an Institute of the Architects of that country, is in a promising state of progress, but we regret that the efforts for the establishment of a similar one in the United States, have proved abortive. The Institute of Civil Engineers has maintained a high rank, and the president has worthily followed the example of his brother president, the noble Earl De Grey, in his sedulous attention to the duties of his office and the interests of the society. The Military Engineers have published the Third Volume of their Transactions, which well keeps up the reputation of its predecessors. In the United States an attempt is now being made to establish an Institute of Civil Engineers, which we earnestly hope may be crowned with success.

Having dismissed the general interests of the two professions, we believe we may refer to our exertions with some complacency. We announced last year that the pressure of matter would oblige us to increase the size of the Journal, and we have accordingly, with the exception of one number, issued during this year an enlarged edition at one shilling and sixpence. That this was called for by the wants of our subscribers has been proved by the successful results of this measure, and we trust that we may appeal to our columns whether we have exerted ourselves in a manner worthy of this support. In the present volume will be found nearly five hundred closely printed pages, and above two hundred wood engravings, among which are those of the Synagogue in Great St. Helen's, the Athenæum Derby, the Pont du Carrousel, Bow Bridge, the Arc de l'Etoile, the Nelson Column, and the Club Chambers Association. There will also be found the Reports on the Great Western Railway Enquiry, on Steam Vessel Accidents, on the Caledonian Canal, and on the Stone for the New Houses of Parliament; a series of papers by Ralph Redivivus, Candidus, and on the Theory of the Steam Engine, by A. Aristides Mornay; on Railway Curves, and on Harbours, a Memoir of Trevithick, the Designs for the Nelson Memorial; and translations from the French of Arago's Life of Watt, and De Clairac's Ancient Marbles.

To our correspondents we have been much indebted for their valuable contributions on many occasions, and we can assure them, sincerely, that nothing shall be wanting on our part, at all times to show every attention to their communications. The Journal has always been open to every thing of merit, and, we trust, we shall never be found remiss in doing justice to any subject committed to our charge.

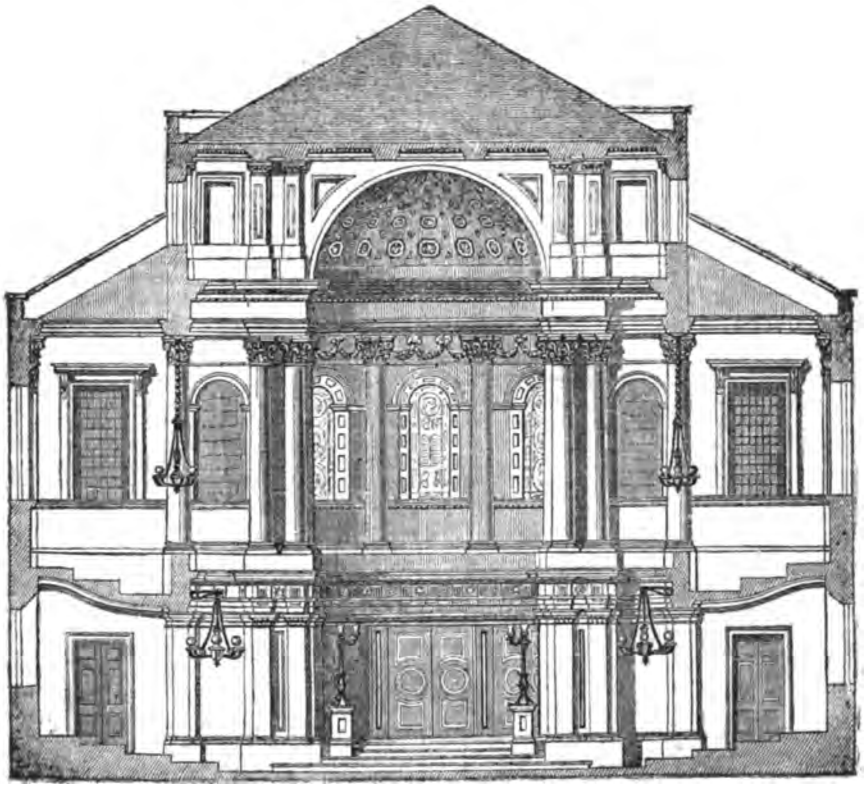
THE

CIVIL ENGINEER AND ARCHITECT'S JOURNAL.

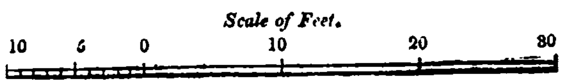
THE NEW SYNAGOGUE,

GREAT ST. HELEN'S, BISHOPSGATE-STREET.

J. DAVIES, ESQ., ARCHITECT.



SECTION.



On turning to the Index of our last, or we should say our first volume, our readers will there find the pages referred to, where we have already spoken of this building. To the second account there given of it we have now little more to add, except that the cuts will supply information as to various particulars not pointed out at page 339.

The section shows the general style of the interior, and the design of that end at which the ark is placed, also the arrangement of the lamps, and of some of the candelabra; but it conveys no idea of the effect, either as regards splendour of colour or perspective appearance. Most of our readers, however, will, so far from requiring to be reminded of this, be able to complete the picture for themselves, from the sketch here given; or should they not have done so before, they will now most likely take an opportunity of visiting the building itself. We ourselves have not seen it since it was opened for service, but should judge that it must look particularly rich when lit up; though at such times the effect of the painted windows within the ark must be lost—not, however, necessarily so, because a few gas-burners placed before them on the outside would show to perhaps even greater advantage than by day, and would diffuse a brilliancy and glow over the upper part of that recess. We cannot conclude without congratulating Mr. Davies both on the opportunity he has had for displaying his taste, and the able manner with which he has turned it to account.

The references to the plan of the ground-floor of the front building and lower part of the synagogue are as follow:—

A. Open vestibule or loggia, with arches on coupled Tuscan columns; 29 × 14.6′.

B. Inner vestibule or corridor, communicating with J. J., the staircases to the galleries.

C. The open area or floor of synagogue, 23 feet wide, between the lower sittings, F. F.

D. The readers' platform.—G. G. Waterclosets.—H. Office.—I. Strong closet.—K. K. Staircases in the private residences.—L. Secretary's residence.—M. Warder's residence.

In the other plan is the committee-room, 46 × 22 feet, and O.O.O. the ladies' galleries.

REVIEWS.

A Treatise on the Law of Dilapidations and Nuisances. By David Gibbon, Esq., of the Middle Temple, Special Pleader. London: J. Weale, 1838.

Architecture has its jurisprudence as well as medicine, and equally as connected with the rights of property, as a matter of police, it has been necessarily the subject of extensive legislation. Coming more within the province of the lawyer than of the builder, and being a subject in which the latter is not *tam Marte quam Mercurio*, we derive the greater pleasure from seeing it in the hands of one who is best capable of doing justice to its technicalities. The utility of its study is so evident, that there is indeed scarcely a day in which its necessity is not impressed. Its extent, too, is so great, that almost every branch requires a separate treatise, and it comprehends the laws of contracts, awards, fixtures, dilapidations, nuisances, buildings, sewers, drainage, prescriptive right, highways, &c.

Mr. Gibbon has already obliged the profession with a work on the law of fixtures, and we are now indebted to him for one on dilapidations. It does not diminish the confidence derived from its predecessors, and is written in a plain and intelligible style, and supported by numerous legal authorities.

In the introduction, the author has given a general view of the law on this subject, and then enters into the detail of its branches in the subsequent chapters. In the first chapter we find the law of dilapidation as it affects ecclesiastical structures and lands. The second exhibits, with equal skill, this law as it regards leases, either for life or during a term of years. From this chapter we shall make a few extracts, and show our readers with what ability Mr. Gibbon has treated his subject, although we must necessarily omit the references to the notes. These, indeed, form a most valuable and extensive portion of the work, and illustrate, by various authorities, the law as explained by the author.

For the natural decay of buildings, which is the inevitable effect of time or for fair and ordinary wear, a tenant for years is not, generally speaking chargeable; but for extraordinary decay, caused by suffering the premises to be exposed to the elements, or for accidents happening during the term, the tenant is liable. Suffering houses to be uncovered, whereby the spars or rafters, planchers, or other timbers, become rotten, is waste; but barely suffering them to be uncovered, without rotting the timber, is not waste. Where, after the determination of a yearly tenancy, the landlord had an estimate made of the sum necessary to put the house into complete and tenantable repair, and brought his action for that sum, Lord Kenyon said, "That it was not to be permitted to go for the damages so claimed. A tenant from year to year was bound to commit no waste, and to make fair and tenantable repairs, such as putting in windows or doors that have been broken by him, so as to prevent waste and decay of the premises; but that, in the present case, the plaintiff claimed a sum for putting a new roof on an old worn-out house." In another case, where plaintiff declared on a contract by defendant to deliver up premises in same state as he received them, and merely proved a tenancy from year to year, Gibbs, C. J., nonsuited the plaintiff, saying, "That the obligation was stated too largely. Can it be contended," he continued, "that a yearly tenant would be bound to rebuild if the premises were destroyed by accidental fire, or if they became ruinous by any other accident? He is only to use them in a husband-like manner;" that is, with ordinary care. In Anworth v. Johnson, an action against a yearly tenant, it appeared that the stairs of the house were worn out, new sashes were wanted, the doors were rotten and falling to pieces from decay, latches, keys, and locks, were broken and damaged, and a panel of a door was broken, Lord Tenterden, in summing up, said, "It appears this was a very dilapidated house, when the defendants took it, and they have had a very considerable quantity of work done upon it. The first question is, what are the things an occupier of a house from year to year is bound to do? He is only bound to keep the premises wind and water tight. A tenant, who covenants to repair, is to sustain and uphold the premises, but that is not the case with a tenant from year to year. A great part of what is claimed by plaintiff consists of new materials, where the old were actually worn out; for that the defendants are clearly not liable. But if you think that defendants have done all that tenants from year to year ought to do, considering the state of the premises when they took them, the defendants are entitled to your verdict." * *

The covenant to repair must be construed with reference to the nature and condition of the building as to age, &c., though it must be concluded that the house was in proper and durable repair at the time of the demise. If it appear that the covenants have been substantially complied with, and the buildings are in as good condition as, considering their age, they might reasonably be expected to be, the landlord will have no right to complain of dilapidations. For this we have the high authority of Tindal, C. J., in three several cases. In Harris v. Jones, the covenant was to leave the premises in good and substantial condition. It appeared, on the part of the landlord, that glass in the skylight was broken to the amount of 40s., that iron rails, tiling, and coping, were dilapidated. On the part of the tenant it was proved, that he had laid out considerable sums in repairs during the term, and that the premises were, in the whole, in tenantable repair, and in a better state than when demised. The Lord Chief Justice said—"The question is, whether the covenant has been substantially complied with? The defendant was only bound to keep up the house as an old house, not to give the plaintiff the benefit of new work." The Jury found for the defendant. Again, in Gutteridge v. Munyard, the same erudite Judge remarked—"Wherever an old building is demised, and the lessee enters into a covenant to repair, it is not meant that the old building is to be restored, in a renewed form, at the end of the term, or of greater value than it was at the commencement. What the natural operation of time, flowing on effects, and all that the elements bring about in diminishing the value, constitute a loss, which, so far as it results from time and nature, falls upon the landlord. But the tenant is to take care that the tenements do not suffer more than the operation of time and nature would effect. He is bound, by seasonable applications of labour, to keep the house, as nearly as possible, in the same condition as when it was demised. If it appear that he has made these applications, and laid out money from time to time upon the premises, it would not, perhaps, be fair to judge him very rigorously by the reports of a surveyor, who is sent on the premises for the very purpose of finding fault."

Again, in Stanley v. Twogood, where the covenant was to preserve, keep, and have the house in good and tenantable order and repair, Tindal, C. J., held that the question was, whether the house was in a substantial state of repair, as opposed to mere fancied injuries, such as a mere crack in a pane of glass, or the like. That although the state of repair at the time of the demise was not to be taken into consideration, yet it would make a difference whether the house were new or old at the time of the demise.

In Marke v. Noyes, Abbott, C. J., held that under a covenant substantially to repair, uphold, and sustain, the tenant was bound to keep up the inside painting. This, it will be perceived, is requiring such a tenant to do more than the incumbent of a benefice. The decision does not appear to have been very deliberate, and is not altogether consistent with those subsequent judgments of Tindal, C. J., and therefore I think cannot be safely relied on. It is usual in leases specially to provide for painting at stated intervals.

From these cases it will be seen, that principles of law are not strictly enforced in considering what are dilapidations; that of minute defects the law takes no notice, "de minimis non curat lex." Therefore, unless the premises have been much neglected or misused, and are in a much worse condition than they ought to be, it will not be safe for a landlord to take legal measures against his tenant: although, where there are substantial dilapidations, these minute defects may and should all be taken into account.

The following explanation of the law, with regard to the manner in which the tenant is bound to repair dilapidations or restore their value, does not appear to be supported by any legal decision of the judges, and this we regret, for it is a point of great moment to the profession. Certainly, most of the decisions of Tindal (Chief Justice), have a tendency this way; and there is very little doubt that if the question was to come before that judge, he would take the same view of the law as laid down by Mr. Gibbon.

Where any part has fallen away, the tenant is not bound to replace it with new materials, but only with materials of the same value and in the same condition as those deficient ought to have been, had they only been subject to ordinary decay and wear, except from accident or exposure to the weather. In determining this, reference must be had to the age of the building at the time of the lease granted, and to the duration of the lease, and so much ought to be deducted from the cost of new materials as it may be supposed they would be depreciated in value by ordinary wear during the period the materials to be supplied have formed part of the building. Mr. Woods thinks, that in hardly any case could the landlord require more than three-fourths of the new value, and none would occur in which one-fourth ought not fairly to be demanded.

Chapter III. explains the law regarding dilapidation by tenant, without impeachment of waste.

Chapters IV. and V. point out the law when the property is mortgaged, and held by joint tenants and tenants in common.

Chapter VI. relates to party-walls and fences. The author explains numerous points of law concerning the Building Act, which probably has caused more misunderstanding and litigation than any other Act of Parliament; several attempts have been made to amend it, but all to no purpose. We shall give one extract from this chapter, to point out an error regarding the time at which it is imperative to deliver accounts concerning the re-building of party-walls:—

Within ten days after the party wall is built, or so soon after as conveniently may be, the builder is to leave at the adjoining house, &c., a true account of the number of rods in the party wall, &c., for which the owner of the adjoining building is liable to pay, of the deductions to which he is entitled, and an account of all other expenses and costs.

The express directions of the Act are—that the account shall be delivered *within ten days after the party-wall shall be built;* it says nothing about "or so soon as conveniently can be." This ought to be impressed upon the minds of every architect or surveyor, for we know instances in which parties have failed in recovering the value, in consequence of the omission to deliver the account within the ten days.

Chapter VII. explains the law relative to churches; Chapters VIII. and IX. highways, bridges, sewers, sea walls, &c.; and Chapter X. is one of considerable importance; it explains the law touching nuisances, in which the author has taken considerable pains and trouble to collect numerous decisions as to what may be considered a nuisance. We shall give two or three extracts to show the able manner Mr. Gibbon has treated the subject.

In determining what acts are nuisances, we must ascertain the extent of the possessions of our neighbour; and here we may refer to the maxim of law, that he to whom the soil belongs is entitled to all the space of air above to the sky, and of the earth below to the centre. His rights extend perpendicularly above and below his own land, and not laterally, so as to claim any use from the earth beneath or the air above the adjoining land. It is, therefore, not only a nuisance to cause an encroachment or injury to the soil of a neighbour, as if John build a house overhanging the land of Thomas, whereby the rain falls upon Thomas's land, and injures it; but also if John corrupt or annoy the air over Thomas's land by noisome smells or deafening noises, it is a nuisance. But if John, by building or otherwise, exclude from the land of Thomas the air flowing over his own land, and the light which comes through that medium, he does no more than he has a right to do.

It is not every disagreeable smell or noise which I cause on my land, and which the wind wafts to my neighbour's, that will give him a right of action; it must arise, it would seem, from some permanent cause, and occasion him continual annoyance and discomfort; and that to a degree sufficient to depreciate the value of his dwelling-house, and render it less eligible in consequence of the neighbourhood. I cannot be restricted in the fair and reasonable use of my land by any delicacy of sense or peculiarity of habit of my neighbour. A swine-sty, limekiln, privy, smith's forge, tobacco-mill, tallow furnace, and glass-house, set up near a private residence, have respectively been held nuisances. And so a mill for steeping sheep-skins, by which the air was corrupted; a building for manufacturing acid spirit of sulphur, which occasioned noisome and offensive smells; a place for slaughtering horses. It is not essential that the stench raised should be unwholesome; it is sufficient if it renders the enjoyment of life and property uncomfortable. * *

Easements over a neighbour's land can only be acquired by grant or by prescription, which raises the presumption of a grant. Grants of easements are either express or implied. An express grant needs not observation; a grant of an easement is implied in the following case. Where a man, having built a house upon his own land, conveys that house to another, he thereby impliedly grants the easement of light over his own land to the windows of the house, as it then stands, and neither he, nor any person claiming under him, will be permitted to derogate from his grant, and build upon the adjoining land to the obstruction of the light. And, in like manner, where an unfinished house is granted with openings for the windows, or ground is leased upon condition that the lessee shall build thereon in a specified situation according to a certain plan, the gantor or lessor, or those claiming under him, cannot build upon the ground adjoining, so as to darken the windows of the house, when finished according to the plan. And where a house and the land adjoining are conveyed at the same time to different persons, and the land is described as building land, the purchaser of the land cannot build so as to obstruct the windows of the house, because it must be presumed that the easement of light was conveyed as appurtenant to the house, and the land was conveyed subject to that easement. * *

The prescriptive period of twenty or of forty years must be the period next before the commencement of the action or suit in which the claim is brought into question. And, therefore, where a party brings an action for the obstruction of his light, he must prove that he has had the uninterrupted use of the light for the twenty years immediately preceding the action.

The usage must have been uninterrupted, but no act or matter is deemed an interruption, unless it has been submitted to, and acquiesced in, for one year after the party interrupted has had notice thereof, and of the party making or authorising the same to be made. Thus, if windows have existed for twenty years, an occasional obstruction will not affect the prescription; but if any such obstruction has continued unabated for a year, the prescription will be wholly destroyed. In like manner, if the owner of the house has pulled down his house, and not rebuilt it with windows in the same situation within a year, or has blocked up the windows for a year, his right will be gone. Though a disuse of the right for a shorter period would not, I apprehend, be deemed an abandonment thereof, so as to interrupt or destroy the prescription.

A prescription for the use of light may be destroyed by an alteration of the manner in which it is enjoyed, as by altering the size or situation of the apertures through which it is received. Thus, where a party, having the right to light, carried out the wall of his house, and made a bow window in the new wall, in the same elevation as the former one, it was held that the easement was gone, since he had no right to receive the light through the new window. But it has been considered that the enlargement of an ancient window will not of itself destroy the prescription, so as to entitle the owner of adjoining land to obstruct the passage of light into any part of the space occupied by the ancient window. And where a building, which had been a malt-house, was converted into a dwelling-house, Macdonald, C. B., ruled that it was still entitled to so much light as was sufficient for the purpose of making malt, though not to any greater quantity. And where a party was entitled to lights by means of blinds fronting a garden, and took away the blinds, and thereby opened an uninterrupted view into the garden, Lord Kenyon held that the proprietor of the garden was not justified in making an erection which diminished the light heretofore coming into the house through the blinds. From the modern decision of Garritt v. Sharpe, it would seem that, in all these cases, it ought to be left to the jury to say whether the nature of the aperture is essentially changed. Where there is a right to pen back water by means of a dam, and the dam is destroyed, the party has no right to erect another dam in a different situation. And where one has a right to ancient pits by the side of a rivulet, for the watering his meadows and cattle, and they are choked with mud, he may cleanse, but cannot enlarge them, or dig other pits.

We have made several extracts, to show the value of the book to the architect and surveyor; it has our entire approbation, and we are encouraged by Mr. Gibbon's existing contributions, in the hope that he will again devote his ability to the elucidation of some other branch of architectural jurisprudence.

Companion to the Almanac, for 1839. Knight and Co.

By this time, most probably, the greater part of our readers will have provided themselves with this little work, and could we be assured that such were really the case, we should not return to it. Yet, as our conjecture is grounded chiefly upon the belief that they would procure it if aware of the highly interesting architectural notices it contains, we shall make a few extracts from it, more especially as there is nothing whatever either on the title or in the advertisements of the publication to point out that it affords the kind of information just alluded to.

The "Companion" may be truly characterised as an exceedingly valuable annual *multum in parvo*, for, besides many scientific articles and statistical reports, it gives abstracts of Parliamentary documents and acts of Parliament, a chronicle of the session of Parliament, a list of public petitions, and a chronicle of occurrences. Another very useful feature, though a minor one, is the necrological table of literary men and artists, both foreign and English. After this mention of the usual contents in general, we shall particularise those alone in the present volume which are akin to the character of our own Journal; we, therefore, point out the two articles on "Steam Navigation" and the "Railways of Great Britain."

The buildings most fully described are the Synagogue, Great St. Helen's; the interior of the Fitzwilliam Museum; the Eastern Institution; the Railway Terminus, Euston-square; the London and Westminster Bank; the Athenæum, &c., at Derby; and the Victoria Rooms, Bristol. Many others, however, are spoken of or commented upon, including those at the Highgate and Norwood Cemeteries. Referring for these to the publication itself, we shall extract only what is said of High Cliffe, Hants:—

The splendid mansion of Lord Stuart de Rothesay, which, after having been in progress for many years, has now so far advanced towards completion that many of the apartments are fitted up. The style adopted for the exterior is not a little remarkable, being formed upon continental models of domestic Gothic, contemporaneous with our English Tudor, and, independently of its novelty in this country, highly striking for the richness and variety of the details, and the care and precision with which they are wrought. The principal fronts are entirely of stone, and that facing the sea has, in addition to a profusion of other decorations, a parapet *à jour*, or of open work, forming mottoes and inscriptions in Gothic characters. On this side subordinate ranges of building branch out from the body of the mansion, so as partially to form a kind of court, enclosed by three sides of an octagon, whose elevations, although somewhat different in design, all agree in being elaborately enriched. Among other distinguishing features is a magnificent oriel, forming an open tribune or balcony gallery on the level of the upper floor. The north, or other principal front has a spacious arched carriage porch, flanked by lofty octagonal turrets, which latter are crowned by ogive dome roofs and finials; and between them is the splendid window, and decorated gable, which form that end of the entrance hall. This hall, which is about sixty feet in length, by nearly forty in height, has also a range of windows in the upper part of each of its sides, the wall beneath them being wainscotted, and panelled with reliefs in stone. The pavement is inlaid somewhat after the fashion of mosaic, in patterned compartments, variegated with numerous badges and devices; and the ceiling, or roof, is of oak timber, carved. At the north, or entrance end, is a handsome stone screen, with a gallery above it, immediately under the great window, which is entirely filled with compartments of painting representing the genealogy of Jesse. At the opposite end is the staircase, consisting of an ascent on each side, in a single flight, with a superb railing of wrought metal highly gilt. Between these flights of stairs is the door leading into the ante-saloon, a spacious octagon fitted up in the Louis Quatorze style, in carved oak and gold, and with costly marble doorcases. This room communicates with the principal apartments—viz., the state drawing-room, library, dining-room, &c.

Dibdin's Northern Tour—(continued).

We now resume our notice of Dr. Dibdin's Tour, and proceed to cull from it the chief information it contains as to the modern buildings and architects of Scotland. Most of the latter, who are noticed, by him at all—for we have not met with the name of Mr. Burn, although we have heard him spoken of as a man of very high abilities and attainments, and zealously devoted to his art—are spoken of in terms of unqualified praise: we hope justly so, for to say the truth the Doctor deals so largely in puff that his praise goes for very little.

Of the wholesale puff we have a choice specimen, when he calls "Auld Reekie," or the "Modern Athens," as it has heretofore been styled, "*a City of Palaces, the* Genoa of the North." Both the italics and the capitals are his own, and are, no doubt, intended to give all possible emphasis and energy to the compliment. Yet one more *mal-a-propos* could hardly have been stumbled upon; since, so far from looking like a city of palaces, Edinburgh has far more the appearance of city of barracks; nor can anything be more dissimilar than the style of its architecture and that of Genoa, the one being as naked and frigid as the other is exuberant and pompous. What could have caused the Doctor to utter such rhodomontade? Was it the effect of one of those *symposia* which he chronicles with so much gusto? Very possibly it might; since, otherwise, it is perfectly unaccountable. One thing is certain, that there is nothing whatever in the book to bear out this assertion; whereas he might very well have cut short some of his gossip, and employed himself in pointing out and describing some of the architectural features that entitle Edinburgh to the epithet of the Genoa of the North. Or else, instead of giving views of its most dismal and downfally holes and hovels, and such exceedingly uninteresting, as well as hackneyed subjects, as the Regent Murray's house, he might have favoured our eyes with some specimens of its magnificence. Without perplexing ourselves any further by questions and remarks that must be rather perplexing to the Doctor himself, we will begin quoting at once.

With all its architectural attractions, the New Town of Edinburgh is defective in two material points. It wants a fine church, and a noble square. The church of St. George, at the western extremity, is a dwarfish representation of St. Paul's at a distance, if its dome only be considered. At hand it shrinks into insignificance, and is flat and tame. There is no bold projecting portico, and the quantity of dull surface above the entrance, to the springing of the dome, is a sad and striking failure. The church of St. Andrew, at nearly the eastern extremity of George-street, is a most inconceivable failure.

This, it must be owned, carries something to the *debit* side of the account, though by no means so much as ought to be, for a great many more deficiencies, defects, and failures, might be pointed out, while there is scarcely a modern building that rises above mediocrity of design, or of which more can be said than that it is endurable. In venturing, however, to find fault, and that, too, in the most unqualified manner, with St. Andrew's, the Doctor quite upsets Mr. Britton's opinion; for if we may rely upon the taste and critical acumen of the latter antiquary, "it is distinguished by its fine tapering spire, and a bold Corinthian portico." For our part, we greatly incline to the Doctor's opinion, and even Britton's own plate of it quite confirms it, since at all events it there looks like "an almost inconceivable failure." In likening St. George's church to St. Paul's, the man of "Bokes" seems to speak by the book, and after the fashion of that which tells us St. Paul's at Liverpool is a miniature imitation of St. Paul's at London. To be sure a dome is a dome all the world over; but the man, and much more the critic, who can perceive any semblance between that at Edinburgh and the one in London, is in great danger of mistaking his wife's bonnet for his own beaver.

That the Doctor did not bestow the epithet he has chosen for Edinburgh unadvisedly, is evident enough from the first sentence in the following quotation, where he speaks of some of the living Scotch architects.

I have more than once called Edinburgh a *City of Palaces*. Of course architecture is the sole means of achieving this splendid result; but if the materials for building were not at once abundant and lasting, as well as picturesque in tint, such an effect would with difficulty be produced. Where to begin? How to describe? *Hic labor—hoc opus est*."

This, it must be confessed, is exquisitely *naive*: how to eulogise—there seems to have been the puzzle.

But it cannot be done successfully—at least to my own taste. Here is James Gillespie Graham, Esq., with a genius all over Gothic; rich, original, tasteful.* Would that be were employed to case the whole of the Castle in a coat, cut according to the fashion of the early part of the fifteenth century. Then, again, I would have him put an ecclesiastical vestment over the whole of St. Giles's, or the mother-church, in the fashion of the fourteenth century. He would do it *con amore*; nor would he displease his own times or posterity if he raised the tower a good fifty feet, and reconstructed the "imperial crown" thereupon, as it is called, upon more intelligible principles of Gothic art.

In Grecian and Roman architecture a love of taste, and yet more of truth, induces me to place Mr. Playfair at the head; simply because he has not only

---

* We cannot withhold the Doctor's own note here introduced. "My friend, Mr. Mackenzie, took me one day to call upon Mr. Graham, more especially to view his design for the new House of Commons on the Gothic plan. It is very magnificent; but perhaps in too detached buildings; while Mr. Barry's, on the contrary, from its continuity, has too much the air of a large manufactory, which, however, may be broke (broken) by a boldness and variety of relief in the external ornaments. Mr. Graham's talents are likely to be successfully employed in the restoration of Glasgow Cathedral." We should like very much to know what are the manufactories of which Mr. Barry's design has at all the air of.

had the opportunity of doing great things, but of doing them well. His Academy of Painting, &c., is doubtless his masterpiece; but for just proportion, it should lose just one-fourth of its length. But the pride and glory of Mr. Playfair's interior, is the Library-room in the University of Edinburgh. It is at once lofty, broad, and commodious, and of a very singular construction in the arrangement of the shelves for the books. There *is* a point where you may stand, and although the room be one hundred and ninety feet long in the clear (longer than any library at Oxford), yet you shall not obtain the sight of a single volume. The ceiling is lofty and gilded; but why does good Mr. Playfair consider burnished gold to be a heresy? In such a magnificent interior you can hardly be too brave and saucy in the upper ornaments.

"Saucy" is a rather queer—certainly not very tasteful expression, except as it may serve to denote that poignancy of flavour so greatly studied by artists of a different class.

Having got among the books in the library, the worthy Doctor flies off in a tangent, without bestowing another syllable upon either "good Mr. Playfair," or any other architect; nor does he touch on the subject of architecture again until he reaches Glasgow, when he speaks of the Exchange as

One of the noblest commercial rooms in Europe, whether we consider its interior or exterior design, its facilities for carrying into effect all the objects for which it was built, or its spaciousness, lightsomeness, and beauty. I was infinitely struck and gratified with it. The architect is no less a personage than David Hamilton, Esq., who without scruple or flattery may be called the Vitruvius of the North.

Scruple he certainly has none, but we suspect that our Doctor does administer flattery in very large doses, weighed out, not by apothecaries' *scruples*, but in pounds avoirdupoise weight. With him, almost every person he names is of superlative merit, therefore he makes his praise so dog-cheap, that those who really merit it find it hardly worth having. Of this we have proof in the very next page, where he goes on to say—

Here, as at Edinburgh, the late Robert Adam has done a considerable stroke of work, in the architectural department; and some things, especially in the Assembly Rooms, and the Andersonian University, are executed with more than his ordinary skill. Of churches there is no proud or particular display; but one or two recent ones, from the designs of Mr. Hamilton, show a great improvement in the department of ecclesiastical architecture. The two principal squares of Glasgow, are those of St. George and Blythswood. The former is in the heart of the city, the latter at its western extremity. Within the former are erected the bronze statues of Sir John Moore and Watt; and at this moment the foundation stone has just been laid for the erection of a lofty triumphal pillar to the memory of Sir Walter Scott. To me the taste of it is perfect. The *Spartans* have here shot a-head of the Athenians.

Judging from the plate given of it, which is said to be an "accurate representation," we must totally dissent from the praise bestowed on this column; for it is nothing more than a meagre fluted Doric column, with a capital of most insignificant proportions and character, and with a base whose tori are enriched with guilloches and other carving! What degree of invention is shown, may be inferred when we say that, like others of its kind, this column also has square abacus to its capital, as if intended to support an architrave. The only recommendation such pillars have is, that any thing like a human figure will do on the top of them; yet they always look top-heavy. We trust that we shall have no such puerile enormity perpetrated in the centre of Trafalgar-square.

Of the cementing in the same city the Doctor says—

The very entrance, over a bridge across a river bestud by one of the most elegant arches of stone ever witnessed, is full of classical feelings; adding in a note, "David Hamilton, Esq., is the architect. He cannot for the soul of him commit a blunder. Mr. Bryce, an architect of Glasgow, has erected a façade of the time of our James I., of which the opposite plate is a faithful copy; and it must be allowed that he has been singularly happy in all its component parts." This last sentence is also accompanied by a very curious note, viz.—"I recommend Mr. John Bryce first to be the architect of every park entrance in Scotland, and afterwards in England. But let it not be supposed that he is confined to the period of 1600-1650. His Tudorian elevations are fraught with the most felicitous features and effects."

What Mr. John Bryce's "Tudorian elevations" may be we know not, having never seen any specimens of them; and with us the Doctor's prescriptions—i. e., his recommendations—obtain very little credit. As a sample of what he can tolerate, if not very eulogistically extol, he presents us with a view of the mansion at Abbotsford, to which, if the original bears any resemblance, it must be perfectly detestable—one of the most hideous specimens of architectural balderdash and bathos ever perpetrated. Happy would it be for the memory of Sir Walter's taste were it razed to the ground.

Since this article was in type, we have received some information relative to Mr. Gregory's splendid mansion at Harlaston, correcting the Doctor's errors and misstatements respecting it. But we must now defer communicating it till next month.

Illustrations of the Public Buildings of London, with Historical and Descriptive Accounts of each Edifice. By Pugin and Britton. Second Edition, greatly enlarged, by W. H. Leeds. In 2 vols. London. John Weale, 1838.

In our last number we informed our readers of the object of this work, and presented some extracts from the preface; we now, therefore, avail ourselves of the opportunity of taking a more general view of the subject. We cannot, however, dismiss the preface without requesting the attention of the reader to the admirable remarks on criticism given by the editor. They point out with force and truth the advantages which the profession must derive from extended investigation, and the necessity of freeing ourselves from the trammels of superannuated pedantry. In this age of steam, we have a right to distrust whatever is old, and particularly when the Elgin marbles have produced a new style of art, and the study of the true antique given a different impulse to architecture.

To the general reader this work must afford many points of interest, but to the architect it presents a double attraction; first, that he contemplates the glories of the metropolis of the empire, and next that he himself may become a contributor to its splendour.—"Io anche son pittore" is a remark well to be expected from the professional spectator of St. Paul's or the new London Bridge. The metropolis has, indeed, in this century attained a grandeur which our fellow citizens may admire, and of which our artists may be proud. It has, as it were, been so created that the extent of its limits are not yet ascertained; we flutter still between the recollections of the past and the existencies of the present day. We are too apt to think of the old city, or to contemplate the vast mass in its political divisions, and thus lose the conception of the immense ensemble.

With no superior in the Asiatic world, and none but inferiors in this, an Englishman may look down upon the modern queen of the world and prize it as one of the phenomena of that empire, which is the greatest that has been established. But it is not on immensity alone, or on artistical riches that this supremacy is based; the historical associations which it recalls are so entwined with the annals of our race as to shed a brighter lustre on its crown. It is well for those who can do no honour to the present day to exaggerate the glories of the past; but to the thinking mind the splendour of an illustrious name is not reckoned by centuries of homage, but by the depth of genius and the strength of thought. We can resuscitate the Attic theatre, or in imagination hear Cicero's eloquence wake the ruined forum from the sleep of ages; but we, who have such susceptibilities, and such a burst of sentiment, can leave the tombs of native bards unhonoured and unsought. If the arts are to be inspired from sources so sublime as the poet's song and the warrior's deeds, we want no Athenian to teach us what is great, nor a Roman to precede us in the art of copying; but we have it here in the streets trod by the busy crowds, in the halls devoted to the national laws, and in the temples consecrated to the public worship. Here the greatest of the modern bards have first seen light—here has been the theatre of their exploits; and in Westminster Abbey more honoured names repose than in any shrine in Christendom. To repeat all these localities, to tell over the sacred ground, would be a task as inexhaustible as the glory of its subject; but we cannot refrain from calling the attention of the reader to some among the many great men who had here their birth-place. Among the poets, artists, and musicians, are—Chaucer, Spenser, Ben Jonson, Fletcher, Milton, Cowley, Pope, and Gray; De Foe, the immortal author of Robinson Crusoe, Bolingbroke, Gibbon, and Lillo; Lord Bacon and Barrow; Hogarth, Bacon, Banks, and Nollekens; Arne, Arnold, Boyce, Aldrich, and Greene; Hampden, Howard, and William Penn.

These are names to which he who can attach no associations should never add the disgrace of belonging to a kindred profession. We think, however, they are such, of which, while no city can boast the equal, so any might feel justly proud. They have left us their immortality, and if we cannot equal them in our works, at least we can decorate that metropolis on which they have conferred the lustre of their names. This is a duty which, we feel happy to say, has been in no way yet neglected, and which every day is meeting with a greater fulfilment, and we may justly feel proud in reflecting that we have not in our days been remiss in fulfilling that service to posterity which our ancestors bequeathed to us. Since the year eighteen hundred so much has been done that it has almost effaced what previously existed, and to such a degree, that a person of the last century would justly feel astonishment at the new world, in which all his former recollections would be lost.

The metropolis, on the east, has been extended into Essex and Kent; on the south it has advanced to the tops of those hills from which it is perhaps again to make farther encroachments; on the west it extends to Hammersmith, and has thrown numerous suburbs to the opposite bank of the Thames; while on the north, again, other villages have been drawn into the vortex, and sacrificed their rural character. These new districts include Pimlico, the several branches of Chelsea, the whole space from Kentish and Camden Towns through the Regent's-park to Bayswater, great part of Clerkenwell and Islington, another section at Hackney and Kingsland, on the east, besides the suburban accessions, the greater portion of the docks, and on the south large tracts from Greenwich to Wandsworth. The whole of this district has been supplied with light and water by new means, and increased facilities of communication by canal and railway afforded with the whole of England. It forms, indeed, a mass extending at least twelve miles in length and eight in breadth, with two millions of inhabitants.

The new lines of street which have been erected are not of less importance. On the south a grand entrance from the continental road leads over London-bridge, through King William and Moorgate-streets to the New-road. Another crosses Blackfriars into Farringdon-street, and a third over Waterloo-bridge into Wellington-street. On the north are the Edgeware-road and Regent-street, while Pall-mall and the Strand have been re-constructed, and two magnificent lines of road branch off through Poplar and Mile-end to the eastern counties. Over the river new bridges have been thrown of various constructions, and include New London Bridge, Southwark, Waterloo, all by Rennie; Vauxhall, by Walker; and Hammersmith, by Tierney Clarke. Our squares and public places, which are justly the admiration of Europe, have been equally increased, and include Trafalgar-square, the place before the Mansion-house, Eaton-square, Belgrave-square, Park-square, Euston-square, and above twenty others.

Nor have the isolated buildings been less numerous: in every department works of importance have been executed. Buckingham-palace, by Nash; the Council Office, State Paper Office, Bank of England, Law courts, by Sir John Soane; the Post-office and Judges' Chambers by Sir Robert Smirke; the National Gallery and University College, by Wilkins; the British Museum and King's College, by Smirke; there are also the Colleges of Surgeons and Physicians, City School, Blind School, &c. The charitable institutions are extensive, Bethlehem Hospital, Christ's, St. George's, Westminster, and others. The municipal buildings have attained great splendour, and include Fishmongers and Goldsmiths Halls. The churches are too numerous to admit of any lengthened enumeration; among them—are Marylebone, by Hardwick; St. Pancras, by Inwood; St. Luke's, Chelsea, by Savage; and St. Dunstan's, by Shaw. The theatres include Covent-garden and Drury-lane, by Wyatt; the Haymarket, by Nash; the English Opera and St. James's, by Beazley; and the Colosseum, by Burton. Commercial buildings and clubs have also increased to an extent unprecedented, and greatly contribute to the ornament of the city.

Public monuments and statues have been erected to the Duke of York, to George the Third, Pitt, Fox, Duke of Bedford, and Canning, while those which are in progress assure the splendour of this branch of decoration.

All the Parks have been improved, and an addition made to them in the Regent's-park, which presents a unique feature in this world of novelty. The Regent's-park and Surrey Zoological Gardens have been formed, and Botanic Gardens are in progress, while the number of Cemeteries must greatly contribute to the health of the inhabitants.

Former edifices have been improved, or placed in better points of view, and made to promote more powerfully the adornment of the metropolis: among these have been St. Martin's, St. Bride's, St. Saviour's, and the Monument.

All these improvements necessarily call for a history in themselves, and to the volumes of Pugin and Britton the profession are greatly indebted for the information conveyed. The rapid growth of the metropolis, however, and the increase of novelties, had long since called for an addition to this work, but until the present period without success. The public spirited publisher now having the property of this work, has, however, supplied this want, and we are happy to say in a manner worthy of himself, and of the object concerned. The editor, too, in taking upon himself the task of producing this work, found that his efforts must not be confined merely to chronicling what is new, but that it might be beneficially exerted in remedying some defects which existed in the labours of his predecessors. He found that in many cases extraneous matter might be removed, which, however interesting to the general reader, was by no means useful to the professional student, and in doing this he availed himself of the opportunity of introducing the new matter without increasing the expense and consequently the bulk of the volume. At the same time he has amended the old subjects, by introducing some further professional information, and rectifying some of the errors which are inseparable from a work of such discursive character.

The subjoined extract relates to St. Pancras Church, and while it cannot fail to prove interesting to the reader, will afford him a fair proof of the manner in which Mr. Leeds has acquitted himself of the task which has devolved upon him:—

Whatever may be alleged against some of the combinations it presents, this church stands unrivalled as a correct example of the richest and most graceful variety of the Hellenic Ionic style; we say *style*, in preference to order, because it embraces so many distant modes, some of which have little else in common than their family characteristic, the voluted capital, and even that marked by striking differences, both in its mass and details. Previously to the erection of this building we had, with the exception of that at the India House, hardly a single Ionic portico of any note in the whole metropolis—certainly no instance of one applied to a church—since for such purpose preceding architects seem invariably to have had recourse to the Doric or Corinthian, in which, perhaps, they showed their judgment; for the Ionic known to us before that from Greece was introduced here, was the most insipid and inelegant of the orders, although complimented with the epithet due only to that from which it proved its descent, by its egregious falling off from it. But were it on no other account, this church would stand pre-eminent among its predecessors and contemporaries for the classical air of its portico, in which no quotidian features are allowed to obtrude themselves; while the three doors are of such exquisite design and admirable execution, that they serve as a climax to the beauty of the whole façade. They are, in fact, specimens of the most refined taste in detail and embellishment. Would that a tithe of the praise could be extended to the side elevations, where, had there been no more than the upper range of windows, that might have been tolerated; but the small oblong ones beneath them are decidedly injurious to the design, marring its Grecian physiognomy. The east end presents both a pleasing and appropriate deviation from the ancient temple plan, and the roof of the projecting hemicycle combines agreeably with the pediment; still the effect would have been all the better had there been only the three centre windows. The low square wings, attached at the angles, give play and variety both to the plan and elevation; at the same time, they do not interfere with the outline of the principle mass. In themselves, these features are exceedingly beautiful, and a very commendable adaptation of one of the choicest architectural relics of classical antiquity. The chief thing to be objected against them is, that the architect has not connected them with the body of the edifice, by carrying on the mouldings of their antæ as a sort of string-course along the side elevations, and resting the windows upon it, which would have required these latter to be raised but a very little higher than what they now are.

The article of theatres has been retrenched in what related to matter of purely general tendency, and its place has been supplied with some judicious comments on the plan and construction of these edifices, which we know cannot fail to be gratifying to whoever has considered the subject. It also contains a well-digested table, exhibiting the relative dimensions of various great theatres.

It must be confessed that our theatres are susceptible of much improvement, being so planned at present that many of the audience can neither hear nor see properly. This has been erroneously attributed to the large size of some of our houses, for in the very largest of them, all might both see and hear distinctly, were it not that accommodation in the way of mere sitting is made for a far greater number than can possibly be accommodated in regard to the purpose for which, it is to be presumed, they come thither—namely, to enjoy the performance. Many are placed, not at too great a distance, but much too near—thrust quite close upon the proscenium and up to the actors themselves; some directly on one side, so that they can see the stage only obliquely; while others are elevated so much above it, both in front and on the sides, as to look quite down upon it, and obtain almost a bird's-eye view of it. These inconveniences are increased, when, as is the case at Covent-Garden and in many foreign theatres, the house expands from, or in other words, contracts towards, the stage, so that those in the side boxes cannot obtain even a side view without turning very considerably to the right or left. Besides which, every variety of such form, the oval, or elliptic, is architecturally disagreeable in itself, being attended with a degree of irregularity offensively perceptible to the eye.

The semicircle is unquestionably the best figure, because it brings all the spectators, even those placed at the extremities of its chord, facing towards, though not exactly in front of, the stage; for it in fact cuts off what can properly be termed side boxes, or such as are at right angles, to the diameter or chord. Yet a simple semicircle would be objectionable on more than one account, because the stage would then be placed on the *longer* side of the area of the spectatory; consequently, as the diameter would give the width of the proscenium (which would be double the depth of the house, measured from the orchestra to the front of the centre box), either the latter must be very great in regard to breadth, or the house itself of small dimensions, or even if not small in itself, yet confined and contracted in comparison with the proscenium and opening of the stage; which inconveniences would bring others along with them, since, were the height of the house to be proportioned to the width of the proscenium, it would become excessive, in comparison with the dimensions in the other direction, and cause the spectatory to appear still more contracted and squeezed up. On the contrary, were it to be regulated by the depth of the house, or semi-diameter, the proscenium would be rendered much too low. This will be apparent to any one, if he turns to any of the plans of theatres here given; by applying his compasses—to that of Covent-Garden, for instance, and taking the line separating the orchestra from the pit, for a diameter—he will perceive it would be reduced to half its present depth, whereby, as he would see on consulting the section also, the height would become preposterous in comparison with such a contracted area.

Still, as the semicircle is by far the most advantageous, it ought to be retained for them, as might easily be done, should the house itself be equal to an entire circle, or somewhat more (as is the case at Drury Lane); and to effect this, nothing more would be requisite than to omit boxes entirely between the chord of the semicircle and the proscenium. Were this done, there would hardly be a seat in any of the boxes that would not command a sufficiently favourable view of the stage; while, in an architectural point of view, all the space so given up or lost, as perhaps it will be considered, would be a decided gain, because it would afford ample field for decoration in connexion with and continuation of the proscenium, so that the whole might be made to form a rich architectural framing to the stage; whereas, according to the present mode, the connexion between the boxes and proscenium is too abrupt, and can rarely be well managed; and whenever the boxes adjoining the stage are comparatively empty, they present a forlorn appearance, which does not at all reconcile us the better to their being in themselves a drawback on the general design. There would be another advantage arising from the system here recommended, namely, that as far as the boxes are concerned, there would be a sort of neutral territory between the audience and the stage, highly favourable to scenic effect and illusion. Every one in the boxes would then be seated where he would behold the stage and performance, not only conveniently, but from a proper distance station. The stage ought to be considered as a picture upon a large scale, and when a man looks at a picture of any dimensions, he neither pokes his nose against it nor does he place himself on one side, so as to view it askew, but in such a manner that he can distinctly behold it. In regard to the stage, however, such certainly is not the case with a very large proportion of the spectators in the boxes. Many of them are obliged to take up with places where they cannot possibly see the scene or *flat*, as it is technically termed, at all, let them twist their necks as much as they will, though *en revanche* they see a great deal more between the wings and side scenes than is either necessary or proper. * *

We shall here put together a few particulars relative to some of the principal theatres hitherto erected; not with the expectation of satisfying the reader, but rather of inducing him to prosecute the object further by his own researches; and the following table, it is presumed, will be found both interesting and useful, as exhibiting a comparative and synoptical view of several of the most important structures of this class:—

	From Curtain to back of Boxes.	Width across Boxes.	Width of Curtain.	Depth of Stage from Curtain.	Height from Pit Floor to Ceiling.	Saloon.
	Feet.	Feet.	Feet.	Feet.	Feet.	Feet.
London.—Opera House	102	75	40	35		
Covent Garden	73	63	32	59	54	56×19
Drury Lane	70	70	32	48	60	90×26
New English Opera	57	55	32			
Paris.—Opera	78	52	40	..	52	96
Theatre Feydeau	52	64	48			
Cirque Olympique	86.6	83	44			
Bordeaux	64	62.6	39.6	70	57.6	
Milan.—La Scala	94	78	44	..	75	100×24
Naples.—San Carlo..................	90	76	49	76	80	82×20
Venice.—La Fenice..................	72	67	42	45	49	56×32
St. Petersburgh....................	102	96	52	99	92	125×30
Berlin	61	58	38	..	43	
Hamburgh	69	68	39	..	56	
Mentz	65	58	38	..	43	
New Orleans........................	73	71	41	..	66	129×26
Dublin	64	62	33			
Birmingham..........................	44	45	28			
Turin	66.6	52	40	98		
Ghent	68	60	37	..	..	82×40

From this it will be seen that the London Opera House, although of the same extent as the Great Theatre at St. Petersburgh, measured on a line from the curtain to the back of the boxes, is considerably less in its other dimensions, and consequently very different in its proportions; it being narrow in comparison with its average breadth, owing to which, and to the contraction towards the stage, the greater part of the persons in the boxes are not placed even at right angles to, but actually turned obliquely from, the stage; as will be seen by the plan of it, and still more palpably by the section, which shows a considerable extent of the side boxes, whose fronts would not be visible in such representation were they at right angles with the curtain. Another great defect is the absence of proscenium, the boxes coming quite up to the opening of the stage, in consequence of which preposterousness in the plan, all architectural expression and propriety are destroyed, and a disagreeable flimsiness takes place, giving to the whole house the appearance of having been hurriedly fitted up for some temporary purpose. Besides which, this immediate contact of stage and boxes would render it almost impossible to cut off the flames from communicating to every part, should a fire break out among the scenery. In Schinkel's new theatre, at Berlin, the proscenium is formed by exceedingly massive walls; and the spectatory itself has the advantage of not being extended greatly beyond a semicircle. Covent Garden partakes in some degree of the faulty plan adopted in the Opera House, as the boxes between the semicircular portion and the stage are carried, not at right angles to the latter, but sloping towards, and consequently inclined from it. Had the boxes been continued on the sides for no more than a third of their present extent, this would have been of comparatively little moment; but as these sloping sides are protracted to such a distance that an entire circle might be described between the centre box and the proscenium, the spectators in the boxes nearest the stage are better stationed for reconnoitering the audience, than for viewing the scenery or the performance. Therefore, at least three of the boxes on each side should have been shallower than the rest. The plan of Drury Lane is decidedly preferable in every respect to that of Covent Garden, as well in the arrangement of the vestibule, staircases, and approaches, as in the form of the spectatory itself. It would indeed have been better had it not exceeded a perfect circle, that is, had the distance from the centre box to the curtain been no more than the diameter of the pit. Yet, notwithstanding that the general form itself is good, it exhibits an adherence to the erroneous practice of continuing the boxes beyond the semicircle facing the stage. We will not be so rigorous as to insist that they should in no degree be suffered to extend beyond that diameter or line, but most assuredly, the less they were to do so the better.

We have now extracted at some length from this admirable work; but we only fear that, although at some extent for our columns, not sufficiently to gratify the wishes of the reader. We know, indeed, that although ancient knowledge may be useful as the basis of our studies, we shall only be able to carry them on effectively by attention to the progress of the present. To all those, therefore, who are desirous of ascertaining the actual state of art in the metropolis, and of availing themselves of it, we can only refer them to this work, which will not only give them food for their observation, but teach them how to exert it.

It has thus been our lot to criticise a work devoted to criticism, but such is the fate of all publications, and to which our own must submit. Criticism must take its food from everything like death, for, in the words of Horace—" Pallida mors equo pulsat pede regum turres, pauperas que tubernas."

We feel happy, however, that, as brethren, it has not been our fate to disagree; but that on the other hand we are enabled to bear testimony to the correctness with which the editor has carried out the principles declared in his preface. Publishers are but too little looked upon in these things, but we must bear in mind that they are entitled to something more than the organ-blower's meed. There is much judgment to be exerted in the choice of a work, and often much boldness in the manner in which expense is incurred, and he who well carries out a great work is as well entitled to praise for his discrimination and public spirit as the author or editor himself. We are happy, therefore, in affording our tribute to the manner in which the publisher has complied with his duty, and not the less so that he has chosen in Mr. Leeds, one whose exertions deserve to merit the confidence of the public as much as his own.

Collection des principaux Monumens d'Architecture Bizantine, Gothique, &c., de la France. Paris, folio, 11th number.

Ornemens Classiques executées d'apres les Peintures Originales de Jules Romain et de ses Eleves. Paris, 4to.

These publications are the fruits of our Parisian neighbours' rage for the Renaissance. The first is the introductory number of a work on the early architecture of France, and includes the Byzantine, a style of which we know little in England. The second is a collection of the arabesques of Guilio Romano and his pupils; and they are both works of reference of which we have a deficiency here.

Herculanum und Pompeii Vollstandige Sammlung der Vis auf den neutigen Tag daselbst entdeckten Malereien, Bronzen, u. s. w. Enthaltend sammtliche in der Antichita di Ercolano, dem Museo Borbonica und dem ubrigen bisher erschieuen Werken, mit Neuern noch unedirten Aegenstanden vermehrt. Von H. Roux et Ad. Bouchet, Deutsh Vearbeitet von Dr. A. Kaiser. (Complete Collection of all the Herculaneum and Pompeian Paintings, Bronzes, Mosaics, &c., described in the Antiquities of Herculaneum, the Bourbon Museum, and the latest Works. Translated into German from the French of H. Roux, sen., and Ad. Bouchet, by Dr. A. Keiser.) Hamburg: Meissner.

This splendid work is to be completed in two hundred numbers of four plates each, great octavo, six of which have already appeared. The first division of the work, containing the paintings, is to consist of architectural ornaments, groups of figures, single figures, friezes, landscapes, and mosaics. The second division includes statues, busts, lamps, &c. The work is cheap and well got up, and cannot fail to promote the knowledge of these elegant styles.

Le fabbriche e i Monumenti cospicui di Venezia di Leopoldo Cicognara. A. Diedi e G. Selva. Venice: Folio (in Parts).

A work on the arts from songless Venice, and where but a few years ago even painting was extinct, is an unexpected occurrence in these days, and we hail with pleasure this promise of new life in the countrymen of Canova. It is needless to say that the public buildings of Venice possess an interest which is not local, but one which speaks to all European associations.

Polytechnischen Journals. Edited by Andrew Romberg, of Hamburgh. (1st Quarterly Part.) Altona: Hammer.

This is a new weekly German periodical, devoted to the different arts and sciences, and contains, besides accounts of improvements in arts, machinery, and manufactures, articles on architecture, and particularly on practical building. It is indeed a kind of extended Mechanics' Magazine, and shows an anxious disposition on the part of our German brethren to profit by our progress, it being the avowed object of the public to take advantage of those opportunities of obtaining information from the manufacturing countries which are afforded by the extent of steam navigation at Hamburgh.

Nouvelles Experiences sur l'Adherence des Pierres et de Brigues. Par M. Morin. Paris. 4to.

This work gives an account of several experiments made by M. Morin, at Metz, in 1834, on the adhesive power of stones and bricks placed in a bed of mortar or cement. These experiments were executed by means of windlasses or ropes affixed to the stones and bricks; and the work further describes the tension which was exerted on these motive powers. As M. Morin gives nothing beyond the recent experiments at London, we have not thought it necessary to go at greater extent into the work, although the minutiæ are treated very elaborately.

LITERARY NOTICES.

We have examined the article on Railway chairs in Crelle's Berlin Architectural Journal, Bd. 11, p. 100, but we have not observed anything of which to avail ourselves. The improvements suggested are of doubtful utility, and great labour has been bestowed in establishing a comparison with other modes of construction. We do not concur in this comparison, and particularly as while the American plan is founded for temporary purposes, and the Belgian suited to a level and sandy country, they can afford no criterion upon which to decide for other circumstances.

The Churches of London, by George Godwin, jun., F.S.A., assisted by John Britton, Esq., F.S.A., &c. Parts 21 to 24.—This work continues to give the same interesting historical descriptions of the ecclesiastical edifices of the Metropolis as the former numbers we have previously noticed. It would add considerable interest to the work if a few more interior views were given, and likewise plans of the churches. The latter might be given in an appendix to the present volume.

A Course of Military Surveying, including Instructions for Sketching in the Field, Plan Drawing, Levelling, Military Reconnoissance, &c., by Major Basil Jackson.—A very useful elementary work, suitable for the student; it contains several valuable hints for military surveying, and description of various instruments, the latter principally borrowed, as acknowledged by the author, from Mr. Simms' work on the use of instruments.

Treatise on Isometrical Drawing as applicable to Geological and Mining Plans. Second Edition, with thirty-five Engravings. By T. Sopwith, F.G.S. —We have no time to spare for noticing this work in the present number. We will endeavour to devote our attention to it next month. It having arrived to a second edition, shows that the work is justly appreciated by the profession.

The Life of Telford shall be noticed in the next Journal.

The Improved Builders' Price-book, containing upwards of 8,000 *Prices and* 2,000 *useful and important Memorandums and Tables*, by W. Laxton, Surveyor and Civil Engineer. Twelfth Edition.—This work has been revised and corrected throughout, and published in a new form, a size adapted for the pocket, which will be a great convenience. It contains a larger number of prices than any other book of the like description.

Mr. Foulston's work on the public buildings in the west of England erected from his designs, will be noticed in the next Journal.

We have great pleasure in announcing that Mr. Wyld has determined upon enlarging his highly useful work the *Index to the Times*. It is to be published as before, monthly and at the same price of one shilling, and will give above three thousand references to the five morning papers, the *Times, Morning Chronicle, Morning Herald, Morning Post,* and *Morning Advertiser*, showing the day of the month, number of the paper, and of the page and column in which the article is to be found.

Among the new periodicals to be started with the new year is the *Sybil*, a monthly publication of literature, philosophy, and the fine arts.

Mr. Timothy Claxton, who is well known by his exertions for the enlightenment of the working classes, has now in the press a book, called *Hints for Mechanics on Self-Education and Mutual Instruction*. Appended to this is some of the most valuable matter relating to Mechanics' Institutions which has yet been published.

ORIGINAL PAPERS, COMMUNICATIONS, &c.

RALPH REDIVIVUS.—No. 12.

THE PANTHEON, OXFORD-STREET.

Perhaps it is a most fortunate circumstance for the reputation of the original structure, and for the credit of the taste of its applauders, that no record of it remains in engravings, save in a few, which are such excessively trumpery ones as to be palpably graphic libels. Nevertheless, making all allowance for most execrably bad drawing and execution, I have never seen anything to warrant one tithe of the praise bestowed on the building, or that could be taken as an indication of either masterly invention or excellence of other kind. On the contrary, supposing any of those representations to have been tolerably correct in regard to general design, I should say that while the whole manifested a littleness, not to say paltriness of taste, there were also numerous improprieties and faults for which much better taste in decoration would hardly have atoned. Such is the impression made upon me by the few views I have seen of the interior, and which I ought therefore perhaps, to take for granted must have very grossly falsified it, it being else next to impossible to account for the unqualified terms of admiration in which it was eulogised. There is indeed one way of solving the mystery, namely, by presuming that for the encomiums bestowed upon it, it was indebted far more to the want of discernment on the part of the public, which blinded them to its defects, than to their discriminating perception of the beauties so liberally ascribed to it. I am all the more inclined to adopt this hypothesis, because I have never seen it critically appreciated anywhere, but merely spoken of in general terms of pompous rhetoric and panegyric. Nothing is easier than to bandy about a set of superlatives and fine-sounding epithets; but in nine instances out of ten it is exceedingly difficult indeed to particularise any one of the excellent qualities attributed to the thing itself by wholesale. In matters of art, if in nothing else, the *vox populi* is not at all to be trusted. It is apt to make up in noise for deficiency in sense. In regard to architecture more especially, this same *vox* was least of all to be relied upon during the *seventies* of the last century, at which period the Pantheon had just risen, and was hailed as a marvel and eighth wonder of the world, at any rate of the London world. It was quite a novelty as a place of amusement, and completely verified the adage of "Omne ignotum pro magnifico." Highly fortunate was it, we repeat, both for its own reputation and that of its admirers, that the first edifice was burnt to the ground; for had not such event occurred, in all likelihood the wonder it would now have excited would have been of a very different kind from that it first produced.

Should we, for want of satisfactory evidence as to what it really was, have formed a too unfavourable and an unjust opinion of it, we can only regret that James Wyatt himself should have behaved with such indifference towards this his first production—certainly not his last in point of celebrity—as not to publish a series of architectural drawings of it on a liberal scale. Had he done so, we should now be at no loss to understand what his Pantheon really was. In neglecting to do so, he was either highly imprudent, or the reverse; most likely the latter, unless we are willing to believe, that the Pantheon greatly eclipsed every thing else he designed in the same style. Without going quite so far as the author of the "Contrasts," who very summarily terms him "James Wyatt, of execrable memory," I cannot help thinking that the architect of the Pantheon was praised greatly beyond his deserts. Had he been less *cried up* in his day, his name would, in all probability, have stood very much higher than it now does at the present moment. He who is certain of applause beforehand, will seldom exert himself to deserve it; while the flatteries of his contemporaries persuade him that there cannot possibly be any hisses in store for him from posterity—that is, supposing him to bestow a single thought on posterity, which is scarcely ever done by any of the petted minions of fashionable patronage. To be sure, there are persons in the world who profess a most philosophic contempt for posthumous reputation. James Wyatt appears to be one of them; his merits seem to have been chiefly negative: he avoided the grosser errors of his predecessors. His generally bald and frigid style of design, which the public of that day were good-natured enough to accept as classical simplicity, afforded no room for grotesqueness and eccentricity, for heaviness and exaggeration. The women had laid aside their formal stomachers and long ruffles, and put themselves in the array, "arm-pit waists," and clear muslin *à la* Adam Buck: in like manner did Wyatt strip architecture of much of its cumbrous old-fashioned finery, till he almost cut off the very hem of its robe.

With the exception of one or two designs for Gothic buildings, all the rest appear to have been put together upon the "save-trouble" principle. They exhibit no study, no *con amore* feeling, no attempt at character; nor do I know of any epithet which would describe them so appropriately as that of "lack-a-daisical." As buildings, indeed, they may be perfectly unexceptionable, but as productions of art they are absolutely nought; nor can I call to recollection one that deserves to be rescued from this sweeping censure. Of the exterior of the Pantheon an adequate idea may be formed from what it was previously to the late alterations, for when the edifice was rebuilt after the fire, the front was restored, with only some trifling alterations from the first design; consequently, it could never have possessed much architectural pretension externally. Whether the porch was erected in strict conformity with the original, I am unable to say; but it certainly was a most contemptible specimen of architecture, with its ugly sham pediment, like a triangular board stuck upon it; and mean iron rails, that seem intended for no other purpose than to afford a stay to the pediment, and prevent its being blown away. This bit of trumpery has been removed by Mr. Sydney Smirke, who has further improved the general appearance by adding four more columns in front to the porch, fluting them, putting them in pairs, and thereby reducing the excessive width of the intercolumns. Even those who are decidedly opposed to the practice of coupling columns must admit, that in this case, there was hardly any other alternative; because, to have reduced the width of the intercolumns by merely dividing them, by inserting a column in each, would not only have rendered them as much too narrow as they were originally too wide, but would have occasioned one of the columns to be in the centre; while the addition of only two columns, so as to convert the tetrastyle into an hexastyle, would not have sufficiently remedied the defect. One defect, to which no remedy has been applied—probably because the architect was not allowed to devise any—consists in the great disparity between the front and lateral elevations of this porch.* The Venetian window above the porch remains as before, and certainly conveys no very favourable idea of the great Wyatt's taste.

As rebuilt by Mr. S. Smirke, the interior of the Pantheon displays much invention, and several good points of design, not only in the large hall or bazaar, but in other parts of it, and not least of all in the conservatory or in-door garden, which forms the approach from Great Marlborough-street. Much more, indeed, might have been made of it, but we ought to be thankful for the practical example of a highly pleasing novelty, instead of objecting to it, that the idea is capable of being greatly improved upon. The idea itself was probably derived from the conservatories at the Colosseum; but that circumstance in no degree detracts from this particular application of it, as Mr. Smirke has produced a design of quite a different character, and in a situation where a garden of this description is most desirable, and where such a one would add materially to the *agrémens* of a house in town; because, while it would present a highly agreeable scene in itself, and might, if lit up, be enjoyed of an evening as well as by day—if not otherwise, at least from the ground-floor windows looking out upon it—it would also serve to exclude the sight of dull brick walls, and other disagreeable objects.

THE ORIGIN AND USE OF THE STEAM DREDGING MACHINE.

COMMUNICATED BY THOMAS HUGHES, ESQ., CIVIL ENGINEER.

The honour of having first applied steam power to the purposes of dredging has been assigned to various engineers at different times, but it will be found on examination that the greater part of those who have hitherto laid claim to be considered the contrivers of this great addition to the resources of the engineer, have no other foundation for their claims than that of having at periods not long subsequent to the erection of the first steam dredging machine, constructed engines on the same principle.

From the evidence of living witnesses, who are no other than the very men who first worked the dredging machine by steam power, as well as from documents in my possession, I can prove beyond the possibility of doubt, that the first steam dredging machine ever used was constructed by my own father, the late John Hughes, in the execution of several contracts which he undertook for the Corporation of the Trinity House.

The following extracts, from a report by my late father, details the necessity which gave rise to the introduction of this new power, and goes on to show the difficulties he met with in the practical application, and how at length they were all overcome by the production of a dredging engine, which may almost be denominated perfect, when we consider the trifling value and importance which can be attached to any improvements made up to the present time.

When the docks at Blackwall were being formed for the East India Dock Company, it was found necessary to deepen the bed of the river Thames at the moorings opposite the dock gates. With this view the Corporation of the Trinity House were employed for nearly two years, at the expense of the Port of London Committee; but at the end of that period they abandoned their pursuit, as being impracticable, after incurring an expense of from sixty to eighty thousand pounds, because their ballast spoons and other implements were not sufficiently powerful nor properly constructed to penetrate the strata, which, at this part of the river, consist of strong blue clunchy clay, intermixed with layers of rock. Well knowing that these strata were impenetrable to all the ballast-lifting implements of that day, and that the Corporation of the Trinity House had, at the suggestion of the House of Commons, advertised for engineers and others to furnish plans for raising ballast upon an improved principle, I immediately, in the absence of my well-known and respectable partner, Mr. William Bough, then attending to a large contract we had at the Dartmoor prison, wrote and suggested to him a mode or principle of a floating steam engine, to work a dredging machine, that I thought would fully answer the intended purpose; to this he readily agreed. I immediately set about preparing it, which I was able to do in about three months; and as soon as it was ready, I proposed to the Port of London Committee to deepen and finish the East India moorings. They accepted my proposals, and I became the contractor. When I was ready to commence operations, the Port Committee came down to see the working of the engine, and were exceedingly sanguine about the success of this (at that time) novel and singular contrivance. Several trials were made in their presence, and I had the mortification to see many parts of the engine, which had cost me much expense and intense thought, torn to atoms, and links of chain, one and a half inch square, broken and snapped off, just as easy as the stalks of so many tobacco pipes, by the expansive power of the steam; finally, the machine was almost torn to pieces, and rendered useless, which was a great disappointment to me as well as to the Port Committee. Having, however, been bound under a penalty to execute the work, it was of no use to reflect on the disasters of this day's trial, which, after all, gave me an opportunity of seeing that the engine had sufficient power to penetrate the strata; but at the same time many improvements were wanting to make the machine equal to its task, it was therefore laid up in Mr. Perry's Dock at Blackwall, and in the course of a few weeks I had many additional friction blocks fixed to prevent breakage, and several other improvements made, which, on the next trial, proved successful, to the greatest degree of perfection, and enabled me effectually to accomplish and complete my contract, to the entire satisfaction of my employers.

About this time Messrs. Milne, Huddart, and Rennie, civil engineers, were employed by the Navy Board to inquire into the cause and nature of the accumulation and deposit of mud, vegetable, and marine substances, at his Majesty's moorings at Woolwich. They were engaged a long time in making the necessary observations, and obtaining the desired information; and subsequently made a long report thereon, which stated that the deposit of mud, &c., in the river at Woolwich, had so increased of late years, as to render the Dockyard useless, and unfit for Government; and where there was a depth of 15 or 20 feet of water, 12 or 14 years ago, there was now no more than six or eight feet. This report ended by submitting to the Navy Board the propriety of allowing them more time to make an actual survey and soundings of the river, which was granted. Messrs. Giles, then eminent land surveyors, were actively employed for nearly twelve months on this tedious and expensive survey. I had by this time constructed, at an expense of eight thousand pounds, a large and powerful floating steam dredging engine exactly on the same principle as the first, on board the Plymouth bomb vessel, which was purchased from Government for this purpose. It was far superior in power to the first, that being only a six horse power, and this one a thirty horse power. I therefore made a proposal to the Board to remove all the deposit at the King's moorings, off Woolwich, and offered not only to reinstate them, but to deepen the river several feet below the original channel. At the request of Charles Cunningham, Esq., the Commissioner at Woolwich, I brought my new dredging machine from Mr. Perry's Dock, where she had been erected, to make trial of the strata and deposit at Woolwich; the trials were continued nearly a fortnight, during which time it was clearly proved, to the satisfaction of the officers of the Dockyard, that the engine was not only capable of removing gravel and sediment, but was actually competent to penetrate several feet into the original bed of the river, which in this situation is an accumulation of mud, gravel, flint, and chalk. In one day we actually excavated and lifted the incredible and astonishing quantity of two thousand tons from an average depth of 30 feet of water, which can be proved by the Government accounts kept by the master attendant and other officers at Woolwich Dockyard. Having so far succeeded we tried no other experiments, but made further proposals to reinstate the depth of the moorings, &c., which

* The same fault displays itself still more offensively in the portico of the Haymarket Theatre. In that of Dover, *ci-devant* Melbourne House, Whitehall, the portico (through which foot passengers pass, as in the one just mentioned, and that of the Pantheon) is much better managed, although it loses much of its effect in consequence of being on a diminutive scale, compared with some of the buildings around it. The façade of Dover House is one of the most tasteful and classical pieces of design in the metropolis. The view of it, in Malton's "Picturesque Tour," shows it to great advantage.

seemed (with the sanction of the officers) to meet with the entire approval of the Board: but by this time the civil engineers beforementioned had brought in their voluminous and conclusive report, stating, that Woolwich was unfit for the purpose of his Majesty's Ordinary, and that the sediment off Woolwich Dockyard had so accumulated of late years, that it would take a period of five years to remove it, and that at an outlay of at least 152,000l.; and after all it would be so uncertain in its effects, that they declined entering into any further particulars, but recommended its being abandoned altogether, and that the Naval Dockyard should be established at Northfleet.

It is well known to every member in both houses of Parliament, at that period, with what violence the propriety of this immense work was agitated, which was estimated at the vast sum of seven millions sterling, or upwards. Pamphlets were written on the subject and circulated in all directions; one, I believe, by the late Lord Melville; another by the late George Rose, Esq.; and several others. We had, however, the satisfaction of being addressed officially, by the Navy Board, requesting us to send them our report to have it compared in all its bearings with the detailed reports of the engineers beforementioned; with this we of course complied, and offered, in open contradiction to our opponents, to reinstate the harbour in eighteen months. This proposition and statement (so much at variwith those of the other engineers) astonished the Navy Board, and they finally declined to decide on the eligibility of one report or the utility of the other; and with this impression, I believe, they laid the whole business before the Admiralty Board. I ought to add, that the plan of the new Dockyard and naval arsenal at Northfleet, was in such a state of forwardness, that the land at Northfleet for the intended docks was actually purchased by Government, and it was at one time fully expected that the works were to commence. But, notwithstanding all these preparations, the Board of Admiralty decided in favour of the mud engineers, with which name we were honoured in some of the pamphlets of that date. The grand work at Northfleet was consequently abandoned, and we, in the end, entered into a contract with the Navy Board, whereby we undertook to restore the Woolwich moorings to their former state. How far this has been accomplished may be easily ascertained by application to Mr. Cunningham, who, I believe, at one time, much to his credit, stood alone unsupported against the opinion of those engineers who advocated the abandonment of the Dockyard at Woolwich.

JOHN HUGHES.

The preceding extract will show that the first steam dredging engine with frames, links, and buckets, was used by my father in the year 1804, in a contract under the Corporation of the Trinity House, at the moorings opposite the East India Dock gates.

Of the advantages that have been derived by the Government and shipping interests of this kingdom, from the means afforded by the steam dredging machine, of deepening and clearing the various harbours, I am quite unable to give anything like an adequate idea. With respect, however, to its application by the civil engineer to the numerous operations connected with the improvement of navigation, it is quite certain, according to the experience of upwards of thirty years, since its first introduction, that a more effective and necessary machine has never been placed under his command.

I propose now to notice the further improvements that were made in the steam dredging engine under my own inspection, whilst managing the dredging operations on the Caledonian Canal, under my late uncle, Mr. William Hughes. In order to convey a proper idea of the great value of the system of steam dredging, as practised on this important work, it will be necessary to give some description of the nature of the country through which the canal is carried, from which it will be seen that difficulties almost insurmountable would have occurred to impede the execution of the canal, had not the dredging proved effectual to the full extent of the most sanguine anticipation.

The line of country which had been fixed on for the course of the canal, comprised three deep and extensive lochs or lakes, extending longitudinally with the canal for the length of thirty-seven miles and a half, whilst a distance of about twenty-three miles intervened between the lakes. Thus it was necessary, in order to complete the communication between the eastern and western shores of Scotland, to excavate between one lake and the other, and afterwards to deepen all the shallows that occurred in the direction through which the canal was to be carried.

The method of dredging which had been pursued by my father, as before described, on the river Thames, and subsequently by Mr. Rennie at the Hull docks, was found perfectly successful in every situation where the machine could float above the spot at which the dredging was required. The position of the buckets, however, required considerable alteration before the engine could be rendered capable of cutting her way across a neck of land, or through the various shoals which occurred on many parts of the lakes. It was accordingly found necessary so to construct and fix the ladder or bucket frame, that when lowered to the working position it projected several feet beyond the bows or stem of the vessel—an experiment, of which the ultimate success was at the time considered very doubtful, and concerning which great anxiety was felt by all those interested in the proceedings. It, therefore, afforded universal and infinite satisfaction to find that the engine worked with the most perfect ease, cutting a passage on the very first trial out of a piece of the canal (which had previously been filled with water for the purpose of floating her) through a neck of land into the eastern end of Loch Doch Four. This work having been accomplished, the engine was successfully employed in removing several extensive shoals which occurred in the lake. At the eastern end of Loch Doch Four where the water from Loch Ness falls into it, close to the ruins of Old Ness Castle, occurred perhaps the most difficult case of dredging that can well be imagined. This was occasioned by the necessity of carrying the canal along the bed of the river Ness, which discharges the water from Loch Ness into the lower level of Loch Doch Four. The bed of the river was composed of an exceedingly hard stratification known by the term mountain-clay; and it would be difficult to conceive anything more calculated to resist all efforts to remove it than this very compact and almost impenetrable substance. It occurs in great masses almost without any appearance of stratification, and entirely free from vertical cracks or fissures. Gunpowder applied in the ordinary mode of blasting was found to produce little or no effect on this clay, as it blew out of the orifice made to receive it without loosening any quantity of the mass.

The river Ness flowing over this primitive and hitherto undisturbed bed, falls into Loch Doch Four with rather a rapid current, and against this the engine had to fight her way, while the duty to be performed was the excavation of the river-bed, to a depth varying from four to twelve feet, and very often the sides had to be widened, and in places where considerable bends occurred in the course of the river, a new channel had to be formed with a breadth at bottom of fifty feet according to the regular section of the canal. It was soon evident when the engine was set to work against the current, and required to tear up the hard bed of the river, that the exercise of every possible contrivance was necessary in order to the fulfilment of this difficult task.

It was at first found impossible to keep the vessel, containing the engine, steadily moored against the current, in consequence of the slipping and giving way of chains, cables, and anchors. The machinery, which was of the very best description, and constructed by the Messrs. Donkin, was quite unable to withstand the immense force applied to it, in order to make the buckets cut into and bring up the excavated clay. All the ground tackle, comprising a full complement of anchors, cables, and hawsers, was first-rate, both in workmanship and materials; the links were of the best Swedish iron; all the bolt-holes were steel-bushed; while the bolts themselves were of the best tempered steel, and case-hardened.

The whole of the buckets were not only made of the best Swedish plate-iron, but had strong pieces of tempered steel-plate riveted to their edges. The friction-blocks throughout the engine were manufactured and fixed with most surpassing care, and could always be adjusted to act with the greatest nicety. Notwithstanding, however, all the perfection of this engine, and the constant care with which every operation was performed, the most vexatious and apparently insurmountable inefficiency, was the result of her first labours in the situation above described. It was no uncommon occurrence to witness, in rapid succession, the tearing away of the buckets, the stripping of the cogs from off the wheels, the snapping of the chains, breaking of bolts, and giving way of the anchors and cables, while on more than one occasion the whole string of chain, buckets, and bolts, was carried overboard.

No sooner were the necessary repairs executed upon the shattered machinery than it was again torn to pieces, and after all no impression was made, no effect produced, on the solid and obstinately resisting mass, against which the engine was contending. Without dwelling upon the various unsuccessful contrivances which were introduced, it will be sufficient to mention at once, that none of these proved effectual until the expedient was tried of removing every alternate bucket from off the chain, and fixing, instead of it, two cutters formed of plates of iron and hardened with steel, which projected at right angles to the line of the chain, and, as this revolved, cut vertically into the ground below. Each pair of cutters, therefore, effected two simultaneous incisions longitudinally in the direction of the vessel, and the lip of the succeeding bucket descending immediately afterwards, scoops up the mass separated by the cutters, and carries it to the top of the frame. After this alteration the work of the engine was performed with much greater efficiency than before; but, in consequence of the hard and incompressible nature of the clay above described, the counter resistance offered to the buckets and cutters would have been sufficient to tear them off and otherwise derange the machinery, had this not been prevented by the action of the friction-blocks. By means of these, whenever a visible tightening and straining of the chain throughout its whole length, denoted that some extraordinary resistance was opposed to the motion of the buckets, the engine continued to work and the wheels to revolve, while the chain and buckets remained stationary. The dredging-vessel was then allowed to drop back with the stream, in order to loosen the bucket, which, being thus extricated from the incision made in the ground, passes back without resistance.

The vessel is then hove up to her original position, and the next descending cutters render the previous incision more perfect, and the bucket immediately following these cutters commonly succeeded in tearing up the obstinate mass. Sometimes, however, it happened that the vessel had to be dropped from her work, and hove to it again several times before this effect could be produced.

These operations, tedious and difficult as they were, succeeded in forming the complete communication between the two lakes in the course of about four months. The distance thus dredged was about 800 yards, and the total quantity removed about 20,000 yards. It must, however, be noticed, that the returns of the work done did not exhibit so large an amount as the above, and this is accounted for by the fact, that a great deal of the material loosened and dislodged by the cutters and buckets was carried down by the stream into deep water, instead of being raised in the buckets to the top of the frame. The excavated earth being in this way as effectually disposed of as if it had all been hauled up by the buckets, it may not appear surprising to learn that the current of the river, although seeming, at first sight, so obviously an obstacle to the process of effective dredging, proved in the way described a great auxiliary to the power of the engine.

Another instance of the immense advantage which may be derived in some situations from the employment of the dredging engine occurred at the west end of Loch Ness. In this part of its course for a short distance out of the lake the canal runs side by side with the river, which descends from Loch Oich, the summit lake, to Loch Ness. The canal attains the level of Loch Oich by means of six locks, five of which are situate above Fort Augustus, about half a mile from Loch Ness, and the sixth at Kytra, about half way between the two lakes. The locks were founded and carried up beyond the reach of water before the canal was excavated on either side of them; and here it will be useful to observe the difficulties which would have presented themselves had not the power of dredging been applicable to this work.

In the first place, any attempt to excavate in the ordinary way between Loch Ness and the ascending locks would have been immediately followed by a deluge of water from the river, and it was certain, on account of the open and inadhesive nature of the strata between the river and the canal, that the water penetrating into the excavation made for the latter would have stood at least as high as the level of Loch Ness, which is the lowest drainage it could possibly obtain. Thus the operations of excavating must have been carried on under a depth of twenty feet of water—a case in which manual labour could not possibly be employed.

On the other hand the expedient of carrying the canal on a higher level, by building two of the locks immediately at the end of Loch Ness, and in this way obtaining drainage into the lake, would have been attended with almost equal objections, for the immense coffer-dams which would have been required in getting down the foundations in such a situation would have seriously increased both the time and the cost of execution. As it was, however, by means of the dredging engine the canal was easily excavated to its full depth and breadth, from the end of Loch Ness to the tail of the first ascending lock.

The application of the dredging engine in the case just described leads us to consider one of far greater importance, where a most difficult and extensive work would have been entirely avoided, had the power of the dredging machine been as well known at that time as it has since become. Every history of the Caledonian canal dwells with great minuteness upon the difficulties experienced in building the sea lock at the eastern end of the canal where it terminates in the Beauly Frith, a part of the Eastern Sea. At this place an embankment was actually carried out into deep water, and after sufficient time had been allowed for its consolidation, the excavation for the lock was formed in the middle of it. This expedient, ingenious at it certainly was, would have been quite unnecessary if the lock had been built on the solid ground inland, and a passage had been dredged out into deep water. Although it is probable, considering the state of engineering knowledge at that time, that the plan adopted was the best that could then be devised, it is certain that a much better work could have been constructed in the solid ground before entering the Beauly Frith, and in corroboration of this it may be mentioned, that the sea lock at this day has a considerable dip or inclination towards the sea, an effect no doubt occasioned by the after settlement of the artificial mound in which it was placed.

With respect to the dredging on the Caledonian canal very little more remains to be said. In various places on the west side of Loch Oich its powers were brought into requisition, but to describe the circumstances of its application at length would be merely to repeat what has already been told, with reference to Loch Doch Four, and Loch Ness.

Without any disposition to disguise the fact that difficulties serious and annoying occasionally presented themselves, I am quite safe in asserting that in every case a persevering and determined application of the dredging engine, in the capability of which every one engaged placed the most implicit reliance, succeeded without exception in a complete fulfilment of the duties expected and required. As it may be interesting to know the quantities of work performed by the engines on this canal, the following numerical statement may safely be depended on. The total quantity of dredging on the Caledonian canal exceeded one million of cubic yards, and the engines employed were only two in number, a six and a ten-horse power. The former of these was employed in the dredging out of Loch Ness up to the first ascending lock, in which district the quantity dredged amounted to 170,000 cubic yards and occupied eight months. This engine was also employed in dredging through the shoals of Loch Doch Four, and between this lake and Loch Ness. The ten-horse-power engine was built at Loch Oich, in the year 1816, and was employed in dredging into the lake, through the shallows, and between the summit level and Loch Lochy descending westward. The greatest quantity raised in one day by the ten-horse-power engine on the Caledonian canal was 1500 tons.

In reviewing the extraordinary performance of the dredging engine in every situation where it has hitherto been employed, it appears to afford to the engineer means of the most powerful and extensive capability in the construction of a class of works which must ever hold a place of great importance in the rank of engineering operations. I allude to docks and harbours, in the construction of which, during late years, the greatest acquirements, both practical and scientific, have been called into action. The well-attested performances of the dredging engine clearly establish the fact that this machine, being set to float in a basin or a channel of water, is capable not only of tearing up and deepening the bed, however hard or solid, but also of cutting away the adjacent land, and extending either the length or breadth of the body of water in any required direction. In the same way the engine would be quite competent, when placed out at sea, to work inland, either to clear out the *embouchure* of old rivers, docks, or harbours, or, as a still bolder undertaking, to excavate new channels where the old ones from any cause have been impeded and rendered useless. The design of constructing docks, harbours, and basins of any kind in sheltered situations, at any convenient distance from the sea, may be safely carried into effect, relying on the power of the dredging engine to perfect the communication with the sea, at an expense not exceeding that of ordinary excavation.

To enter into details respecting the cost of dredging in various situations would be out of place in a paper of this kind, which professes to be a mere outline of its advantages. But I shall at any time feel great pleasure in affording to any individual, or public body, who may think proper to communicate with me on the subject, the benefit of my experience and practical acquaintance from earliest youth, with every particular relating to the practice of dredging by steam power.

4, Acre-lane, West Brixton. THOMAS HUGHES.
December 15, 1838.

ON CONSTRUCTION, AND THE USE OF IRON.

Read before the Architectural Society, on Tuesday, Dec. 4, 1838, by R. E. PHILIPS, Esq., Member.

The great end of all the arts is that of making an impression on the imagination and feeling. That imitation of nature frequently does this I believe will be readily admitted; but that on some occasions it fails, I conceive will also be conceded; the true tests of the arts, therefore, does not rest solely upon the production of a true copy of nature, but whether it answers the end of art, which is to produce a pleasing effect on the mind. Architecture does not rank itself under the banners of an imitative art; but, like music and poetry, appeals directly to the imagination. There is in architecture an inferior branch of art, in which the imagination has no concern; it does not lay claim to its appellation as a polite and liberal art from its usefulness, or as an accessory to our wants and necessities; but from higher and loftier principles, we are convinced that a man of genius would render it capable of inspiring sentiment, and of filling the mind with great and sublime ideas. The influence of the fine arts upon the intellectual and moral character of a people, their utility and their value, as conferring upon a state in which they are justly appreciated as the highest proof of civilization, are considerations which cannot be too much entertained. Persons are too apt to regard the art of design as a mere elegance, as the sign of wealth rather than the production of wisdom, and as more the effect of pleasure than utility. It may be well for the members of our profession to consider what means and materials are in their hands, that may prove conducive to these ends, and whether this art has not in its power to address itself to the imagination by more ways than those usually adopted by architects. That the mere theoretical architect combines those qualifications, has not, I think, been proved in the buildings of the ancients, for I imagine that many of the deformities observable in the buildings of Greece and Rome have arisen from their ignorance of construction, and the modes adopted to supply that deficiency, some of which have been contrary to every rule of beauty and convenience. The strength and duration of their erections may, I think, be attributed to the goodness of the materials, and the quantity used, rather than any practical display of mechanical skill: and, at the same time, I cannot help regretting that at the present day, when the flourishing appearance of the arts would lead us to look for a display both of the one and the other, a sad deficiency exhibits itself, and especially when we are continually hearing the former decried, the latter so much commended.

To the Gothic architects we are considerably indebted for the unity of both, for in their works they exhibit a lightness, an art and boldness of execution, clearly proving that neither the singly practical or theoretical architect will ever exhibit to the mind a pleasing object for its contemplation, unless the union of the two becomes apparent to the imagination by the working of its effects.

England, perhaps, exhibits more than any other nation magnificent examples of these qualifications, equally admirable for the art with which they are executed, and the taste and ingenuity with which they are composed. I cannot here refrain from expressing a feeling of regret, that these structures, sacred to the soil, are not more considered, better understood, and held in higher estimation, and more encouragement given to our antiquarians in that peculiar branch, to undertake a correct publication of our ecclesiastical and domestic architecture, before ruin spreads its extending mantle, and preserve to after ages the remembrance of an extraordinary style, now fast sinking into oblivion, at the same time publishing to the world the riches of a great nation in the splendour of her ancient structures, and rendering a real service to the art of design.

That some of our modern architects have developed great skill and considerable knowledge in their erections, I candidly and joyfully confess; for instance, St. Paul's, and many other works of Sir Christopher Wren, present us with a display of numerous examples of admirable works, executed with so much art, that they are and ever will be studied and admired by all intelligent and researching observers.

> " Those massy columns in a circle rise,
> O'er which a pompous domo invades the skies;
> Scarce to the top I stretched my aching sight,
> So large it spread, and swelled to such a height."

To him and many others we owe great improvements in practice, especially in carpentry, which has been carried to a much higher state of perfection than by any other nation; and we are considerably indebted to many of our countrymen for several valuable books, which have been published, explaining the various modes of conducting the several works, and enumerating the apparatus used, together with the properties and nature of materials adopted; and let me here bear an humble tribute to the periodicals which now monthly add to our store; to these, then, the various structures to be found in the United Kingdom, and elsewhere, must the architect devote much of his attention, in order to acquire and collect the rudiments of construction, and other branches of his profession, which practice, experience, and attentive observation alone will render him consummately skilled in.

Perhaps there is no material so much in requisition in buildings as iron; but yet so little attention is devoted to the parts thereof, that although capable of being converted to the most ornamental purposes, at the same time uniting stability with utility, it is made an eyesore, or, in many instances, a severe reproach on the skill and ingenuity of the architect. The use and advantage of a thorough knowledge of the material will be best appreciated by those who seriously consider the dread effects of a failure in its application, as it would happen most likely when the consequences would be most serious; and, perhaps, there is no material which requires more the aid and assistance of science in its use, therefore the greater necessity for a constant study of its properties and capabilities. That very great improvements have been made in its application is every day more apparent, and which may be chiefly attributed to its great acquisition in manufacturing districts, and thereby produces additional reasons for a more minute cultivation of a thorough knowledge of its utility and value. Another reason for its adoption is on the score of economy, for although the opulence of the nation might warrant a supposition of prodigality in its public buildings, yet where thousands and tens of thousands are squandered in the most trifling, contemptible, and ridiculous modes, yet, in respect to the arts, especially architecture, the public liberality has yet been seen only to extend to almost a mere nothing, a foundation certainly much too weak to sustain an edifice either creditable to the national taste or native genius.

The existence of pure iron was formerly questioned; of the fact that such pieces have been found, I believe there remains little doubt, indeed none at all, if we rely on highly respectable authorities. A large piece of native iron was found in South America in 1783, by a Spaniard, which was found to be pure and soft iron, easily cut, and capable of being wrought without difficulty when heated, some portions of which are deposited in the British Museum, as specimens of the block. It has been likewise a matter of doubt whether the ancient Greeks, towards whom we generally look for authorities as to the early progress in the arts, were acquainted with the use of iron.

In the description of the games instituted by Achilles on the death of Patroclus, translated by Cowper, we find the following:—

> " The hero next an iron clod produced
> Rough from the forge, and wont to task the might
> Of King Ætion; but when him he slew
> Pelides' glorious chief, with other spoils,
> From Thebes conveyed it in his fleet to Troy."—ILIAD.

If iron had been common among the Greeks, we may assume that a lump of the metal of the size described by the poet or his translator would have been no unworthy prize of heroic contention; but as it is by no means clear that the knowledge of iron for military purposes really existed, much less that the art of subjugating so stubborn a material, was at that time known.

At what period the smelting of iron ore, so abundant in this country, was first undertaken, does not, I believe, appear. It will be readily admitted by those conversant in early history, as well as by those who respect traditional probability, that the earliest uses to which it was devoted were probably weapons of warfare. Although a considerable degree of perfection appears to have been attained at a very early period in the working of iron, the art of casting articles in sand from the metal in its crude state seems to have been either unknown or not practised till a comparatively late period. That it is fitted for every purpose in building is not asserted, especially considering the climate of England; but its usefulness for the support of great weights exposed in situations subject to rapid decay, and for the prevention of fire, must be self-evident, as, in the latter case, we have seen several instances lately, which fully bear testimony to the correctness of this observation, where there is every reason to suppose, that, had not the brestummer supporting the front wall of the house been of iron, the same would have been precipitated into the street, and thereby, perhaps, a sacrifice of many lives. There have been instances of failures in the use of this material, which, perhaps, has much prejudiced the public mind against its adoption more generally in buildings; but yet these may have been cases where it has arisen from a want of a proper knowledge of its properties, and not from any defect in the material itself.

Persons are too apt to imagine that a large piece of iron must possess infinite strength, and the dimensions of the most important parts of structures are frequently fixed upon by guess, and from such causes ensues unpleasant consequences. The chief and principal object is to regard the fitness, strength, and durability, at the same time endeavouring to produce, with those qualifications, a pleasing effect, correctness of design, and lightness of parts, yet at no sacrifice to the stability of the erection. When it is considered that the parts of a building should assume any particular form or position, as well as stress, it will become obvious that something more than mere resistance to fracture should be calculated. In the evidence given before the jury on the failure of the Royal Brunswick Theatre, the architects examined on that occasion differed materially as to the application of iron for the purposes of roofs; yet there are many recent instances where iron roofs have been adopted with complete success. I might mention the roof over the fruit market at Covent-garden, where it is composed of iron and wood, that has a very light and agreeable effect; the fish-market at the Hungerford-market is wholly of iron, with sheet-iron (? zinc) covering. In chapels lately erected, the cluster-columns have been made of iron, six inches diameter, cast hollow, with a stone core for their reception, and the height of which, I believe, are 25 feet; but yet, for the want of a little attention to these matters, every body must regret the bad effect which is produced by the introduction of iron girders, in chapels and elsewhere, without combining a spirit of design with that of utility, and perhaps economy; little or no attention is paid to the adoption of iron columns in shop windows where they become necessary for the stability of the building, which, if properly considered, instead of forming a blot in the design, might be made conducive to its general good effect, and that without detriment to its stability or usefulness.

As regards the qualities of iron, we find the following recommendations:—White cast iron is less subject to be destroyed by rusting than the gray kind; and it is also less soluble in acids; therefore it may be usefully employed where hardness is necessary, and where its brittleness is not a defect; but it should not be chosen for purposes where strength is necessary. When cast smooth, it makes excellent bearings for gudgeons or pivots to run upon, and is very durable, having little friction; white cast iron, in a recent fracture, has a white and radiated appearance, indicating a crystalline structure, it is very brittle and hard; gray cast iron has a granulated fracture of a gray colour, with some metallic lustre; it is much softer and tougher than the white cast iron, but between these kinds there are varieties of cast iron having various shades of these qualities, those should be esteemed the best which approach nearest to the gray cast iron. Gray cast iron is used for artillery, and is sometimes termed gun-metal.

The utmost care should be employed to render the iron in each casting of an uniform quality, because, in iron of different qualities the contraction is different, which causes an unequal tension among the parts of the metal, impairs its strength, and renders it liable to sudden and unexpected failures. When the texture is not uniform, the surface of the casting is usually uneven where it ought to have been even. This unevenness, or the irregular swells and hollows on the surface of a casting, is caused by the unequal contraction of the iron of different qualities.

Too much attention cannot be paid by the architect to the fact of ascertaining the capabilities of every portion used, by the necessary proofs, the importance of which has been frequently proved, the castings having been, to the eye, good and sound, but, under the necessary proofs, were failures, but which reflects no discredit either on the architect or founder, but only shows the high necessity for the before-mentioned caution.

I have been led to make these few remarks from a wish that some more able hand, and well-stored mind would, some evening, instruct us with a better and more elucidated detail of so interesting a topic.

The architect who has his mind thus filled with ideas, and made expert by practice, will work with ease and readiness, whilst he who would have you believe he is waiting for inspirations of genius, is, in reality, at a loss how to begin: whereas the well-grounded architect in theory and practice has only maturely to weigh his subject, and all the mechanical parts of his art follow; without conceiving the smallest jealousy against others, he is content that all shall be as great as himself, who have undergone the same fatigue, confirming the importance of the fine arts, and drawing forth a strong response from the generous hearts of all classes, ere a nation may wear that high intellectual honour which the production of masterpieces in painting, sculpture, and architecture has ever conferred.

May we not trust and be persuaded that we shall have the gratification, at no distant period, of adding a new page of lustre to the English history, there being nothing of glory left to achieve, we may still snatch the only remaining laurel in the midst of the enjoyment of peace and plenty; we may, after a long and severe struggle, enjoy those enchanting, fragrant, and ever-blooming laurels of painting, sculpture, and architecture, entwine them round our country's brow, stamp the age in which we live, and, by the patronage and encouragement given to the mass of talent in all the branches of the arts now in this country, if to the glorious names of Augustus, Pericles, and Leo, we may add that of Victoria, as the most enlightened and liberal patroness of the arts since the bygone days of Italian splendour, and make those days in which she ruled the golden age of England's pride.

RAILWAY CURVES.

Sir,—I have recently been engaged in staking out the line of one of the principal railways now in progress of formation, and in the course of my operations met with some difficulty, in consequence of being compelled to cross several roads and rivers, and certain lands, at fixed points. To accomplish this, I was obliged to make use of curves of different radii for shorter distances than usually adopted.

Now, although it is, doubtless, an object in laying the rails, to make the resistance equal by continuing a good working curve, or gradient, as far as possible, yet I think it would be an improvement upon the system of running directly from a straight line to a curve of 1½, 2, or 2½ miles radius, if a curve of 3, 4, or 5 miles radius for a short distance (say 5 or 10 chains, or any distance which the locality would make convenient) were made use of to connect them.

I would add, that projectiles (where the resistance is equal) assume the parabolic curve, to which the plan I propose is an approximation.

If any of your more experienced readers would correct any error I may have fallen into, they would much oblige

Your obedient servant,

Dec. 14, 1838. "A SUB."

THE SOANEAN MUSEUM.

Under the head of "Weekly Gossip," in its number for December 1st, the *Athenæum* has made the following remarks respecting this so-called *public* establishment:—"Whilst upon the subject of Museums, let us ask, are the Soanean trustees still nodding 'in the pleasant land of Drowsihood,' as well as their great prototypes abovementioned? (viz. those of the British Museum). How long is the *Public Inheritance* in Lincoln's-inn-fields to remain a close borough for Mr. So-and-so, the curator, and Mrs. So-and-so, the housekeeper? A rich *Architectural Library* was left, we submit, to be devoured by something else than the dry-rot. When shall we have the use and enjoyment of our heritage? Or has the entrance been removed to *terra incognita?* Two years almost has the testator been dead, yet the British people must still be satisfied with permission to visit *their own property* some few months (rather some few days) during the fashionable season! Let us hope that by next spring such arrangements will have been made, as may render a recurrence to this subject unnecessary."

It affords us great pleasure to find the matter so strongly taken up in such a quarter; for were we solitary in our condemnation of the system of nominal access to, but virtual exclusion from, the Soanean Museum, we might be thought to plead rather for our own convenience, than for the right of the public generally. So long as it continues upon its present footing, the whole is a monstrous piece of humbug—an absolute dog-in-the-manger affair, and as such cannot be too strongly reprobated. As far, too, as the *liberal donor's* memory is concerned, it would be infinitely more charitable towards him, to pay no regard to his childish freaks and whims, but throw the Museum open to the public, "every day and all day long," than, by adhering to them, to remind the public perpetually of his stingy disposition, which induced him to tie up the property in such manner that no one—neither the public nor his own family, can enjoy it; the only parties who can really be said to be in actual possession, being Mr. Curator and Mrs. Housekeeper—the servants of the public—who, no doubt, have full leisure to perform "high life below stairs," or, for the matter of that, upstairs, too. If there be a rich *Architectural Library*, which, after what we have heard, we very much doubt, let all those who can benefit by it have free access to it. The only respect in which the Soanean Museum can now be considered a *pro bono publico*, is, that it seems likely to be a bone of public contention. Let us, therefore, fight for it manfully—no, not manfully, but *doggedly*, until one party or the other get the day. At all events, it is a case wherein the next best thing to a decisive victory would be an equally decisive defeat.

SCHOOLS OF ENGINEERING, MINING, AND SURVEYING.

As very great ignorance seems to exist among the would-be political economists as to the state and progress of the schools for engineering, mining, and surveying, we are induced to publish the following remarks:—The Government have the departments at Sandhurst, Woolwich, and Chatham; the East India Company have also a college; the Royal Dublin Society have long given regular courses of lectures and instruction, under the superintendence of Mr. Griffiths; and surveying has been so effectively taught at the Agricultural School of Templemoyle, that the Ordnance Surveying Department there has received considerable assistance from it. Surveying is one of the regular branches of instruction at Elizabeth College, Guernsey; and we believe also at King William College, in the Isle of Man.

But if any deficiency of these institutions exists, it will be fully supplied by the faculties established at Durham, and in University and King's Colleges, London. In the college in progress at Bath, professional instruction is part of the course proposed, and we have no doubt that it will soon be adopted in Ireland or Scotland. The southern mines will also have a school founded by means of the Dunstanville subscription.

We wonder that the admirers of the Polytechnic School had not pointed out the deficiency of agricultural schools in England, while there are shoals in foreign countries, and there are establishments even in Ireland and Scotland. This would be about on a par with their other reasoning, for although the Irish and Scotch may want agricultural schools, the English do not. "It is not the healthy who want a physician, but the sick."

IRISH RAILWAY COMMISSION.

"Having thus endeavoured to explain, that the construction of the best lines of Railway between London and Dublin, and between Dublin and Cork, the latter being established as the fixed port of embarkation, a more certain, expeditious, and convenient, if not a cheaper, communication would be effected with America, than from any port of Great Britain directly, unless with partial advantages from Bristol only; and that even from Bristol, circumstances are likely to induce many vessels to touch at Cork. We may, then, safely urge the construction of these Railways as a consideration of national importance, quite independent of the amount of direct profit from increased business which the intercourse thus created is likely to produce.—*Page 66, Irish Commissioners' Railway Report.*

I shall now endeavour to examine and investigate the general utility of this plan recommended by the Irish Railway Commissioners, as its main object is put forward on merely assumed data, evidently for the purpose to induce the Government of the country, either to embark in the project, or to advance public money to carry it into execution; and as it is an undertaking not only gigantic, but of a very formidable kind, it ought to be subjected to the test of the stern scrutiny of reason and discussion; because it appears to involve the making of 140 miles of railway through Wales, and also 316 miles through the south of Ireland, and a consequent expenditure of more than ten millions sterling. I shall, therefore, be brief, and approach the subject at once by calling public attention to the time of travelling from London to Cork by railway, as compared to the sea voyage by steam to the same port. The merits of the direct voyage from London to New York—the superior advantages of the route from London to New York, by the Western railway to Bristol, and then direct by steam across the Alantic — the central position of Liverpool, in the British empire — its great American trade, and the many advantages it possesses as a point of general departure for America, and its becoming the great emporium of steam intercourse with the states of the new continent. To the nautical and geographical statements to illustrate and show that the recommendations of the Irish Railway Commissioners, as to Cork being established as the fixed port for embarkation, would be productive of no benefit, either as to general convenience, economy of time, or expense to passengers departing from the port of London, Bristol, or Liverpool, bound to America; and that even the making of 456 miles of railway through Wales and Ireland, would neither lessen the time nor the expense of steam navigation intercourse between the principal ports of Great Britain and those of North America; but on the contrary, if viewed on the basis of national utility, would be attended with immense trouble, inconvenience, and expense, not only in general to the travellers of England and Scotland, but also as to the transmission of packages by that route from Great Britain to America.

It is stated in the Irish Commissioners' Railway Report, that if the line of railway they recommend be made from Dublin to Cork, "and the most rapid possible communication opened between London and Dublin, persons or packages might then reach Cork from London in about twenty-nine hours, allowing twenty miles per hour for railway travelling." The Railway Commissioners have not given any detail of the calculations regarding how the journey from London to Cork by railway could be performed in twenty-nine hours, it may therefore be worth while to examine that statement put forth by them.

	Hours.
Railway conveyance from London to the Irish Channel	11
Steaming across to Dublin	12
Travelling from Kingstown to the Cove of Cork	9
	32

The Railway Commissioners mention that a saving of two or three days would be made in going by railway from London to Cork, as compared with performing the same voyage going by sea. This, upon investigation, does not appear to be the case, for the distance from London to Cork straight through the English Channel is about 595 English miles, which a powerful steamer could perform in about fifty hours in favourable weather, and which would only be a saving by the railway of about eighteen hours instead of two or three days; so that this statement of the Commissioners does not even appear to stand investigation when compared to the circuitous route of touching at Cork.

Looking into this question, and viewing it in another way; supposing passengers and packages leaving London in a steam vessel bound direct for New York in America, they would reach it even sooner than if they were to travel by railway to Cork, and then embark for America; because Cork lies 230 miles north-west of the middle entrance of the English Channel: and again, a ship steaming from London bound for New York, and calling at Cork, incurs an immense loss in running from the Land's-end to that port, her course then requiring to be changed from W. by S. to N. W. 4½ west for a distance of about one hundred and eighty miles, and in place of making southing, which she ought to do if sailing in a direct course, she would be making northing to the amount of not less than 190 miles, taking it from the centre of the mouth of the English Channel to the harbour of Cork. The direct voyage from London to New York would, therefore, possess many advantages in lessening the time compared to the same voyage being performed by going round the Land's-end and calling at Cork; or even going by railway through Dublin to that port, and then embarking for New York. Let it be further observed, that besides the *great expense* of this railway land journey from London to Cork, the embarkation to cross the Irish Channel, the disembarkation at Kingstown, arrival at Cork, and again, the re-embarkation at the Cove, would entail much more trouble, loss of time, expense, and inconvenience to passengers and packages taking this route, than the Irish Railway Commissioners appear to be aware of. But let any one acquainted with travelling just examine for a moment this plan recommended by the Commissioners, and it will appear, that there is neither reason for it, nor any kind of advantage to be derived from its adoption, and much less to the interests of the state; that there should be 456 miles of railway made, costing more than ten millions sterling, at the public, expense, upon such a senseless project, and which could never be of any national benefit whatever in accelerating the communication between London and New York, or the other ports in North America.

Can this favourite project of the Irish Railway Commissioners, so strongly advocated and put forward by them, of London passengers and parcels going through Dublin to Cork, and embarking for America, stand one moment in competition with the route from London by the Great Western Railway to Bristol, and then direct by steam to New York. A glance at the map of Great Britain and the chart of the Atlantic, will show the very great superiority of this line of communication between London and New York, as compared to any other that has yet been laid before the public, and which is now working practically to a great extent, with the most triumphant success. The Great Western Railway from London to Bristol, is wide and level, which will ensure to it a very considerable velocity per hour. The time of travelling on it from London to Bristol may be taken at about four or five hours, and then 28 hours steaming W. by S. towards New York, would place the passengers on board of the steamer at the end of 32 hours after departing from London, not less than 150 miles S. by W. of Cork. I ask, what is the Royal Commissioners' London, Dublin, and Cork project, requiring 456 miles of railway to be made, and costing more than ten millions sterling, compared to this plan, which is now, to a great extent, in full operation.

The Railway Commissioners' reasonings as to the advantages of Cork, compared to Liverpool, are equally fallacious as those which they have expressed regarding London and Bristol. As Liverpool is the largest commercial port on the west of Great Britain, and possesses a very large American trade, I shall offer a few observations in comparing it with Cork, as a fixed point of departure for America, and which the Commissioners very erroneously think will become the great port of communication with the states in the new continent.

	Hours.
Passengers crossing from Liverpool to Dublin, say	11
From Kingstown to the Cove of Cork	9
Amount of time from Liverpool to Cork	20

A powerful steamer departing from Liverpool and bound for New York would, in 26 or 27 hours, with moderate weather, reach the same longitude as Cork, but with a favourable wind 50 miles more southerly; so all that would be gained in point of time would be about six or seven hours, and as to the expenditure of fuel it would only be about 25 or 26 tons. But on the other hand, looking to the many eminent advantages which Liverpool possesses, and above all to her central position in the British Isles; united already to London and Hull by a railway, and also will be with Glasgow shortly—possessing a steam navigation intercourse with Dublin, Belfast, Glasgow, and all the principal ports on the west of Great Britain, and those on the shores of Ireland, her immediate connection with all those great manufacturing districts within the interior of England, the work-shop of the world, and justly exciting the admiration of people from every region of the globe. Looking at her wealth, the extent of her commercial activity, her rapidly growing trade, points out Liverpool, without requiring 456 miles of railway, and a ten million expenditure, to be destined to become the emporium of Britain, for steam navigation intercourse with all the rising states of America. The writer of this is as thoroughly convinced that such will be the case as any mathematician can be of any of the axioms of geometry.

The recommendations and assumptions of the Irish Railway Commissioners as to this important question tend eminently to mislead, not only the government of the country, but also the various companies, and the public. But if they had taken the trouble of examining with the least attention the chart of the Atlantic, exhibiting the eastern and western shores of America and Europe, and the map of the British Isles, they never could have fallen into such a gross misconception regarding the best and most direct routes of communicating by steam between London and New York, and also between Bristol and New York.

Are the Railway Commissioners not aware, that by the chart the course from the middle of the western entrance of the English Channel to New York is about W. by S.? and from Cape Clear, in Ireland, it is about W.S.W. 6¾ west? and further, that the middle of the Atlantic entrance of the British Channel, is north of the parallel of New York about 585 miles, Bristol 743 miles, and Cork 775 miles? and that any northing made in sailing from London or Bristol to New York, by calling at Cork, is a dead loss equivalent to double that amount, because a ship has as much southing again to make by such a deflection from the true and direct course? As to a London, a Bristol, or a Liverpool steamer getting business at Cork to compensate them for such a deviation and delay, is altogether out of the question, particularly looking at the state of the present existing trade in Ireland. The additional supply of fuel which the Commissioners think the Atlantic steamers outward-bound from London would require, and which they recommend should be procured at Cork, it may be observed, in reply, that the steam ships even from London can carry quite enough of fuel to carry them from that port to New York, without incurring a loss in nothing of nearly 200 miles, by calling at Cork; and that Falmouth, in this respect, would afford the supply much better, if required, and without loss of time or lengthening of the voyage. Looking at the geographical position of both Liverpool and Bristol, steamers from those ports would stand less need than those of London in calling at Cork for fuel.

It is presumed these observations show there can be no beneficial results from the making of 456 miles of railway through Wales and Ireland, costing more than ten millions sterling, in lessening either the time or expense in going from London or Bristol to New York, by making Cork the port of departure; unless it be to involve the unfortunate existing executive of Britain in an expense of more than ten millions sterling, and to support one of the most extraordinary projects or jobs that ever was proposed, or even ventured to be recommended to the government of any free country. Yet it has been so far countenanced by those in power, that augmented salaries and honours have been bestowed, marking their approbation of the measure.

In justice I deem it right to give the following quotation:—"The Viscount Melbourne and the Chancellor of the Exchequer state to the Board, that whilst they consider the importance of a safe and expeditious line of communication between London and Dublin to be such as to justify the interference of the public, they are by no means prepared to recommend any survey of a line of railroad. Several private bills have passed, and works are either in contemplation, or are actually undertaken, upon the successful completion of which a direct line of railroad from Dublin to London must depend. They therefore consider that any interposition on the part of the state, even if it were limited to the single object of a survey, would have a tendency of interfering with private enterprise, and discouraging the application of capital, when it may be required for the general improvement of the country."—*Report on Liverpool, Holyhead, and Port Dynllaen Harbours, 21st. Feb,* 1837.

W.

NATIONAL MONUMENTS.

Sir,—No one who knew London fifteen years ago but will see with pleasure how much it has been improved since then, especially near Charing-cross, and that truly noble structure, London-bridge. It would, however, puzzle a foreigner (and it puzzles me who am not one) to account for the incongruity which exists in the names of the principal streets and squares, and of the buildings and monuments that are placed near one another. For instance, how comes it that we are to have a monument of Nelson and Trafalgar-square in front of the National Gallery? Had the building been an Admiralty-office, nothing could be more appropriate; but a name bearing reference to the fine arts, and a monument of Hogarth, of Reynolds, or of some other of our famous artists, would have been more fitly applicable to a gallery of paintings. If bronze statues should (as they generally do) represent none but princes, warriors, or statesmen, King Charles's statue might have been removed further from the scene of his disastrous death, and turned towards the immortal works of the painters he so liberally patronized.

However, I suppose that, in spite of all that can now be said, Trafalgar-square will retain its name, and Nelson's statue will be placed there—at the risk of strangers to our history who have visited our chief towns (Edinburgh, Dublin, Liverpool, Birmingham, &c.) supposing England to have produced so few great men that we have been obliged, in order to have statues enough, to make a dozen for each of them. With the Greeks and Romans, our masters in architecture and sculpture, bravery only was virtue, and warriors the greatest of men; but are we Christians of the same opinion? Why have we not statues of Bacon, of Locke, of Newton, of Howard, or of King Alfred, in our squares and public places? or, if we must have soldiers and sailors, why not one of the great and virtuous Collingwood—of that warrior who, as a husband, a father, a commander, a patriot, and a subject, merits the unalloyed admiration of posterity, and whose whole character and conduct may well be held up as a pattern worthy of all imitation? Surely the monument in Trafalgar-square should be dedicated to both the admirals and to their brave companions also—to the men whose patriotism was not excited by the hope of immortalizing their names, as well as to those whose names were in the mouths of friends and enemies, and will be handed down with those of Cæsar, of Hannibal, and of Napoleon.

With regard to the form of the monument, I would protest against sticking a statue on the top of a column at such a height that it is not to be seen with comfort—unless it be the statue of a cocked-hat, a wig, or a pigtail, for then the farther from sight the better. More especially would I protest against a column with an unornamented shaft, with a detestable iron railing above the abacus, and this supporting a round-topped sentry-box; from the inside of which the half-naked sentinel appears to have emerged in a fit of melancholy madness, with the intention of falling on the pavement below; when the wind blowing on his shivering carcass and on the clothes that hang about his legs, shall overcome his endeavours to stand upon the slippery convexity, and take his feet from under him. If the Nelson monument is to be a statue on a column—1st, let the shaft be ornamented; 2nd, let it not be heavy Doric (*alias* English); 3rd, let the abacus itself form a stone parapet instead of a railing; and, 4th, let the statue stand or appear to stand (from the best points of view) almost immediately above the column, and on a flat surface not much raised from the abacus. Not that I approve of any Stylitic monuments, unless in honour of Simon himself. The Greek column is perfectly unfit for an isolated monument, and I do not know that the Greeks themselves ever made such use of it; nor yet the Romans, until the time of Trajan, when the arts began to decline. A column has an abacus as a preparation for a great weight to be placed above. Without this superincumbent mass it is incomplete and useless; but an isolated monument should be complete in itself, and it should terminate in a point or something nearly approaching one. Prejudice apart, how much more beautiful is the Turkish minaret, the Egyptian obelisk, or a Gothic spire, than a solitary Greek column! For my part, I prefer a well-built factory chimney when the smoke curls from its top, and gradually mixing with the air above it, leaves one with nothing to expect. It only wants a well-imagined railing to carry the eye gradually from the solidity of the edifice to the lightness of the vapour.

While so much has been done for the ornament of the city of London, it is to be lamented that Sir Christopher Wren's monument should still retain its pot of brass flames—the disgrace of English taste—the laughing-stock of all foreigners. It would be infinitely better with a statue; and whose would be more fitly placed there than that of Wren himself? There would be something like justice in that, and the great builder's ghost could not grumble, even though in another world he has improved his taste, which in this was certainly far inferior to his science and his skill.

Yours obediently,

B.

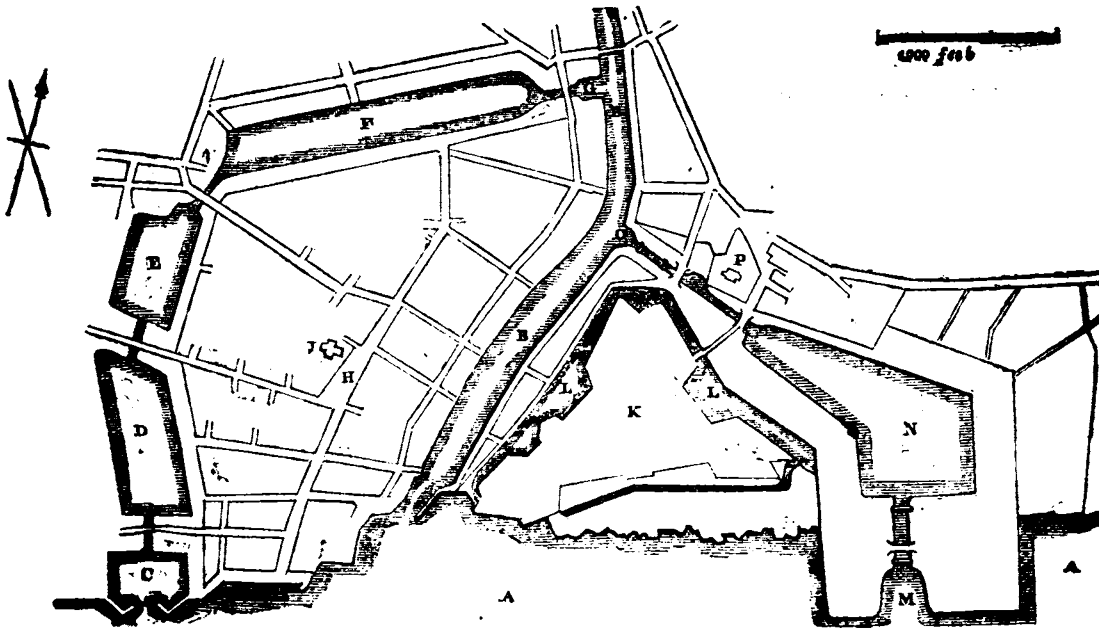
IMPROVEMENTS AT AUGSBURG.

Great activity has prevailed here in improvements, and it shows that in cultivating the fine arts, King Louis does not neglect the useful. An important sluice has been constructed on the river Lech, supplying a thousand feet of water in a second, for the use of the factories. The Protestant and Catholic cemeteries have both been enlarged, and the dead houses ornamented with Doric façades. The great cotton factory begun in April is roofed in, and will contain 30,000 spindles and 800 looms, and is to be worked by water by means of two of Fourneyron's newly invented Turbines, which will give 200 bic feet of water per second at 15 feet fall. To carry off the water, a cut is to be made a mile long, 42 feet broad, and 12 feet deep. A new street has been formed to communicate with the Jakober suburb, and the railway to Munich is in a very advanced state.

PLAN OF A PROPOSED NEW DOCK AT KINGSTON-UPON-HULL.

Designed by James Oldham, Civil Engineer,

To be called the Queen's Dock; *showing its connexion with the Rivers, and the present Docks of the Port.*



(Reference to the Plan).

A, River Humber.—B, the Old Harbour, or River Hull.—C, Entrance Basin to the present Docks.—D, Humber Dock, Area 7a. 0r. 24p.—E, Junction Area, 6a. 0r. 5p.—F, Old Dock Area, 7a. 0r. 24p.—G, Entrance to River Hull.—H, the Market Place.—J, the Church.—K, the Citadel.—L, Moat.—M. Basin to the proposed Dock.—N, proposed new Dock.—O, Entrance to River.—P, Church.

The convenience for trade afforded by the extensive system of docks, has perhaps more contributed than its local situation to the prosperity of Liverpool, while it has fully counterbalanced the difficult entrance of the harbour. Bristol, too, has equally found it necessary to extend its attention towards these entrepots, and it is only, perhaps, owing to the want of a corporation as rich as those two cities, that Hull has not taken advantage of such indispensable adjuncts to trade.

The present Dock Company was established in 1774. Their capital is 90,000l.; divided into shares of 500l. each. They have constructed three docks, occupying twenty-three acres, with quays and warehouses, all out of the profits, at a cost exceeding 450,000l., and they pay a dividend of twelve per cent., besides reserving the like sum to pay off a debt of about 70,000l., contracted to make their last dock.

It is not surprising that the accommodation supplied by this company should be considered insufficient, when at Liverpool alone there are one hundred and eleven acres of dock room and eight miles of quays. The increasing trade of Hull, and its position as the great midland outlet, evidently point out the deficiency, and we need not be surprised if, from the consequent inconvenience, loss of trade has ensued; for Hull does not, like Liverpool or Bristol, bear no rival near the throne, but has at her very doors two powerful competitors, in Grimsby and Goole, which not only attract much of the growing traffic, but threaten the usurpation of the whole.

Here, as Bristol, the existing institutions are attended by defects that tend still farther to aggravate the deficiencies they cannot supply, and like the case of the Great Western, the largest class of steam vessels are unable to enter the present Docks at all, though taxed to an immense amount for benefits which they never receive; for other large ships the accommodation is glaringly insufficient, and the notorious want of quay room is entailing upon shipowners and merchants a delay and expense to which they will not longer submit.

Under these circumstances it has been determined to apply to Parliament in the next session for the establishment of a Company, to be incorporated under the name of "The Queen's Dock Company," with power to construct a new Dock or Docks, thereby putting an end to the mischiefs complained of, and at the same time affording to the promoters every prospect of a handsome remuneration: the capital to be 180,000l., in shares of 100l. each.

The intended site is a piece of ground of about 30 acres, chiefly extra-parochial, lying to the east of the garrison, and extending down to low-water mark in the Humber. The water in front is, at low water, in spring tides, of the depth of four fathoms, and the works will be so far carried out as to give the entrance to the proposed Dock the full benefit of that depth of water. In this situation a sufficient quantity of land can be obtained to afford the amplest quay room, with every other necessary appendage for landing, storing, and loading merchandise of every description. A communication will be made between the river Hull and the proposed Dock.

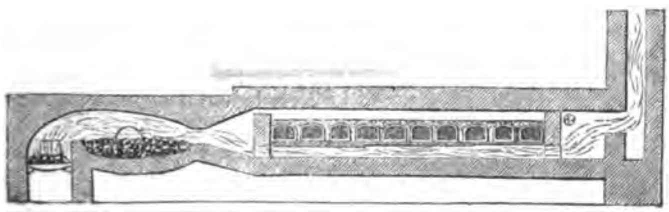
The Dock will contain about twelve acres; the principal entrance will be through a spacious basin extending into the Humber, to a line drawn parallel to the extremities of the piers of the Humber Dock. The basin will communicate with the proposed Dock by a lock of the width of 65 feet, the depth of 35 feet, and the length between the gates of 300 feet, capable of admitting the largest men-of-war or steam ships. The Dock will be excavated to the depth of 35 feet. It will communicate with the Old Harbour at its northern extremity by a short canal and lock of the ordinary dimensions. The quays on the eastern and western sides will be 210 feet wide, affording ample space for warehouses and sheds. There will also be sufficient space on the south side of the Dock for Graving Docks communicating with the Dock for ship-building upon the most extensive scale. The Dock and Quays will be surrounded by a lofty wall, rendering them in every way adapted for the bonding system.

It is not our business to point out advantages, or to lead the opinions of capitalists, but it is a necessary professional duty to see that a project is required or that it is likely to be remunerated; and we certainly consider that in this instance, as the plan is justified by the most urgent necessity, that so it is likely to meet with the happiest results. The income of the present Docks has increased from 24,789l., in 1832, to 37,808l. in 1837; and this latter year was by no means distinguished for its commercial prosperity. The situation of Hull is certainly of the highest importance, for it occupies with the Thames that position on the west of the North Sea, which Hamburgh and Bremen do on the east. With this advantage in position, by its river communication and by the railways, which on one side of the Humber will unite it to Liverpool and the Atlantic, and on the other, by the intended Hull and Nottingham Railway, give it through a rich agricultural country the monopoly of the midland manufacturing district, Hull wants but energy and spirit in its merchants to become the mart of the Baltic and the German Ocean.

THE NEW MODE OF PRODUCING WROUGHT OR MALLEABLE IRON DIRECT FROM THE ORE.

Patented by Mr. William N. Clay.

Fig. 1.—LONGITUDINAL SECTION OF BALLING AND PILING FURNACE, WITH RETORTS.



The retorts are covered with a layer of sand.

Fig. 2.—PLAN.

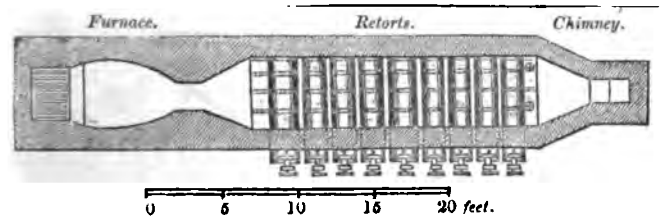


Fig. 3.—TRANSVERSE SECTION OF RETORTS AND HORIZONTAL FLUES.

The O are small apertures to allow a portion of the flame to pass over the top of the retorts. The retorts may be increased or diminished, as the waste heat is greater or less.

REMARKS BY THE PATENTEE.

Iron is popularly divided into two descriptions, cast and wrought.

Cast, or pig iron, is principally a combination of the metal with carbon, which it absorbs from the coke or charcoal of the blast furnace. Wrought iron has been hitherto produced by freeing cast iron from the carbon, &c., with which it is combined: the nearer it approaches to a state of purity, the better wrought or malleable iron will it be.

The richer ores of iron contain the metal combined with oxygen; if that oxygen were separated, the metal would be in its malleable state as wrought iron.

And yet, the advance of science has left this great branch of our national prosperity so far behind, as to suffer the manufacturer still to continue the practice of impregnating the iron with carbon in the first instance, which carbon must afterwards be separated, by tedious and expensive processes, to produce wrought iron of good quality.

But there are other evils in the common mode. It is necessary for the manufacturer to have a sort of glass floating on the molten iron at the bottom of his furnace, to prevent the oxydation of the recently produced metal by the blast. This glass is formed from the earths with which the ores of iron are mixed, and limestone to flux those earths: so that, ores of a very superior quality cannot be used by themselves, but only in part, to enrich such poor ores as have more earths combined with them than are necessary for their own fusion. Thus it is, that the Hematites, and other rich ores, found abundantly in Lancashire, Cumberland, Cornwall, &c., reach no higher a marketable value at the place of their production than the common earthy ores of the coal districts, although they contain twice as much iron, and that iron of a very superior quality.

Again, English iron is, from its mode of reduction, almost certain to be injured to a greater or less extent by combination with sulphur; the earthy ores, which form nine-tenths of those generally used, are impregnated with that deleterious mineral to a great extent; the coals from which the coke is formed are likewise more or less sulphurous; and this gives the high estimation and value to charcoal iron, or such as has been reduced in the several processes by the agency of wood instead of coal.

It is the object of the patent taken out by Mr. William Clay, to produce wrought iron of best quality, direct from the rich ores hitherto so little used from the causes beforenamed, by a process simple, rapid, and economical.

To make wrought iron of such quality, for instance, as chain cables are made from, five several operations are necessary, besides the preliminary one of making the coke for the blast furnace, namely—

1. Roasting the ore.
2. Smelting in the blast furnace.*
3. Refining.
4. Puddling, balling, hammering, and rolling.
5. Cutting up, piling, and rolling.

All these processes requiring a separate application of heat.

It is stated in the article on iron, the 106th number of the "Library of Useful Knowledge," a work written with great clearness, and an intimate knowledge of the subject, that 8 tons 17cwt. 3qrs. 3lbs. of coals are required for the production of one ton of finished bar iron; doubtless, the introduction of the hot blast has reduced the consumption of fuel in the smelting operation considerably, and the adoption of anthracite coal may decrease it still further. It seems, however, yet doubtful, whether the best bar iron can be produced from "hot blast pig:" at all events, very small proportions of that description are as yet used in the fabrication of iron of superior quality.

On the patent plan, the operations are reduced to three; namely—

1. Reducing, or preparing the ore in retorts, or other close vessels.
2. Balling, hammering, and rolling.
3. Cutting, piling, and rolling.

The first of these processes is accomplished by the otherwise waste heat of the two latter, so that only two separate applications of heat are required; and the second operation on this plan commences with the iron in as forward a state as the fourth of the old mode, whereby the cost of fuel and labour, and the enormous outlay of capital in land, blast furnaces, and machinery required to bring iron on the old mode to the third stage, are all avoided.

It is now necessary to state how this is to be accomplished.

Referring to the plan, it will be seen that between a reverberatory furnace of the common construction employed in "puddling," "balling," or "piling" iron, and the chimney, a range of retorts are placed, which are heated on their exterior by the otherwise waste heat of the furnace.†

Into these retorts are thrown 100 parts of Ulverstone, or other rich ore, and 20 parts of coke dust, ground charcoal, anthracite, or other carbonaceous matter, well mixed together. The retort is closed, and the vapours generated escape as gas. In the course of from thirty to forty-eight hours, as the heat is greater or less, the carbon will carry off the oxygen, and leave the iron in a metallic state.

It has then to be taken to the balling furnace, where it welds up, like scrap iron, and in fifteen minutes is ready for the hammer; thence it undergoes the customary process of rolling.

It is then cut up, piled, and rolled, and the operation terminates with the production of bar iron of superior and extraordinary quality.

The fourth operation of the old process, "puddling," takes from one and a half to two hours to perform; the second operation of the patent, only fifteen minutes; consequently, the consumption of fuel will be much less than if refined iron were used. It would be idle to compare the simplicity and economy of the first stage of the patent process, with the cost of the three stages required to make the ironstone into refined iron on the old mode, when we find by referring to page 28 of the work alluded to, that of the 8.889 tons of coal consumed in the whole process, 6.989 tons are used up to the refining, so that the 1.9 tons required for the subsequent operations, may be calculated on as more than sufficient for the patent plan—to which may be added (if the furnaces themselves do not supply sufficient cinders), the one-fifth part of the weight of the ore used, to mix therewith, as carbonaceous matter.

An objection may be made by an iron master that the mode is not wholesale enough—that the retorts contain only hundred weights, while his mighty tower furnaces hold tons. If the question were the production of pig, or cast iron, there might be some weight in this; but the superiority of the patent mode refers more particularly to the production of wrought iron; and here, the largest maker in the kingdom must await the laborious and tedious operation of the puddler—him he can only supply with a few hundred pounds of iron every two hours; so that, the retorts have only to furnish the same quantity, to keep up with the puddling furnace of the present system; if necessary, it might be shown that a balling furnace, on this plan, will produce considerably more than a puddling furnace on the old one.

* In this operation, the expenses of limestone and breaking it have also to be incurred.

† To show what this waste heat is, it is only necessary to state, that the chimneys of these furnaces in the iron districts are compelled to be lined with fire-bricks to the top.

It now only remains to notice the quality of the iron. In no one respect is it inferior to "best common," and in many of its properties it is equal to Swedish or charcoal iron; its tenacity is so great, that of four trials made with patent iron (1 inch chain), at the corporation testing machine, Liverpool, not one broke with a less strain than 26 tons, and one link required 28 tons 12½ cwt. to break it, the standard test for that size being 16 tons.

Experiment on Mr. Clay's method of making bar iron.—150lbs. of Ulverstone ore and 40½lbs. of wet coke (losing 12½ per cent. in drying) were put into one of the gas retorts in Dale-street, on Saturday, Nov. 24, at five in the morning, and remained in till ten on Tuesday evening, or sixty-five hours. The heat was maintained at a full red, or common gas-making heat. The above quantity reduced at the Mersey forge (two miles distant) produced in thirty-four minutes two balls of iron—one of 32lbs., and one of 26lbs.—58lbs. The former rolled to 1¼ inch puddled bar, weighed 30lbs., and was then brought down under the tilt to ⅝ inch square, and samples taken when broken. The yield 38⅝ per cent.

Comparative result of melting iron in a cupola with a mixture of anthracite coal and coke, and with coke alone, obtained from repeated trials:—

Old method of filling and working the cupola with coke alone.

	cwt.	qrs.	lb.
Charge with coke	6	0	0
Ditto limestone	0	2	0
Ditto iron	5	0	0
Ditto coke	0	1	20
Ditto iron	3	2	0

And continue filling ¼ cwt. 20lb. of coke to every 3½ cwt. of iron, as long as necessary.

New method of filling and working the cupola, with a mixture of coke and anthracite raw coal.

	cwt.	qrs.	lb.
Charge with coke	2	0	0
Ditto anthracite raw coal	2	2	0
Ditto limestone	0	2	0
Ditto iron	15	0	0
Ditto coke	0	1	0
Ditto anthracite raw coal	0	1	0
Ditto iron	8	0	0

And continue filling ¼ cwt. of coke, and ¼ cwt. of anthracite raw coal, and 8 cwt. of iron, as long as necessary.

The cost of coke fuel for melting each ton of iron, reckoning the coke at 30s. per ton, is 3s. 8d. The cost of the mixed fuel, reckoning the coke at 30s. per ton, and the anthracite coal at 25s. per ton, is only 1s. 8d. per ton, causing a saving of upwards of 50 per cent.; and the anthracite coal being almost pure carbon, has the further effect of improving the quality of the iron.

This experiment was tried at Messrs. Weber's foundry, Liverpool. The anthracite coal was obtained from the Ystalyfera Iron Works, near Swansea, now erecting under the direction of Mr. E. O. Manby, civil engineer.

N.B. The cupola which is now at work, according to the improved method above described, is 2 feet 2 inches wide inside, 8 feet high, and is blown by a fan blast through a twyere 6½ inches in diameter. The blast was not heated. The quality of the iron was decidedly improved by remelting with anthracite.

FURTHER REMARKS ON THE SLOPES OF EXCAVATIONS AND EMBANKMENTS ON SIDELONG GROUND.

Sir,—Having carefully read Mr. Bowman's contribution to your number for this month, on the above subject, I am induced again to address you. Mr. Bowman having stated the method he has described as being more expeditious and more accurate than that described by me in your Journal for November, in reply to his statement, that it is more expeditious, it could only have arisen from Mr. Bowman's not having practised the method I described; as instead of planting the instrument at each estimated width from the centre, as in the method described by him, I set up the spirit level in such a position as to command the ground backwards and forwards for several hundred feet, in which distance there would necessarily be several widths to set out; but this can be done only on moderately hilly ground. The method I adopt, where the ground is very abrupt and sidelong, is to plant my level so as to command the centre stakes, and as many of the upper widths as possible, which I rectify in the manner I have previously described; I then remove my instrument so as to command the centres and as many of the lower widths as possible, which I alter in a similar manner; in this way the widths on sloping ground, however rapid the fall may be, can be set out with great facility.

It must be very apparent to your readers that once planting the spirit level can be done much more expeditiously than (I speak within compass) half a dozen times with the theodolite—not taking into account the much longer time requisite in planting the latter instrument than the former. As to the greater accuracy, if Mr. Bowman does not impugn the method I think there is no doubt but that with the spirit level is infinitely superior, bearing in mind that the calculations with the latter in the field (simple as they are) is not trusted to the head only, but the readings of the staff, registered (on a waste sheet), and the necessary deductions or additions made; but without this latter precaution I cannot understand why a mistake would be less likely to occur in first reading the level staff, then setting the instrument to the angle of the slope and again reading the staff, than it would be to simply note the difference of level, multiply it by the slope, and correct the distance accordingly. In conclusion, although I would be sorry to be thought discourteous towards Mr. Bowman, whose method I highly appreciate, and in some localities would undoubtedly practise it, yet I much doubt its useful application in the majority of instances.

I remain, &c.,

Charlotte-street, Bloomsbury, PETER BRUFF.
December, 1838.

MOMENTUM OF FALLING BODIES.

Sir,—Oblige me by allowing your Journal to be my medium for submitting the following remarks to the perusal of your correspondent C. E. C., and your other, I hope, numerous readers.

Mathematical works tell us that the momentum of a body in motion is proportional to its weight multiplied by its velocity. I doubt this, and the following is my reason for so extraordinary a scepticism:—

The velocity of a body at rest (or, to avoid a contradiction, of a body all but at rest) is evidently $= \frac{1}{\text{infinity}} = 0$. If m were as $b v$, the force or pressure of a body just moving from a state of rest would be 0; for, as we have already seen, v then $= 0$, and $b \times 0 = 0$, whereas in fact it is b.

I believe that the momentum of a body can never be less than its mass, and that it is equal to the body's mass added to the product of a certain function of the body multiplied by the velocity—or, algebraically expressed, that $m = b + M^{bv}$.

I have some years ago endeavoured to measure the ratio of the momentum to the velocity per second of time. I repeated an experiment after reading your correspondent C. E. C.'s letter, and the following is an account of it and the results I deduce from it:—

Having attached one end of a cord to a weight of half-a-pound, I tied the other end to the hook of an accurate improved spring balance, by Salter, and having made the distances from the hook to the weight successively 16 feet, 8 feet, 4 feet, 3 feet, 2 feet, and 1 foot, let the weight fall these distances, and observed that the scale marked nearly 24lbs, 19lbs, 14lbs, 12lbs, 10lbs, and 6½lbs, so that the power acquired in falling the distances was for a velocity of 32 feet per second = 23½lbs; for 22⅝ feet = 18½; for 16 feet = 13½; for 13¾ feet = 11½; for 11 feet = 9½; and for a velocity of 8 feet per second = 6lbs. Dividing the velocities by the weights, we find that a body falling (or a body in motion) at the rate of one foot per second acquires a force equal to 10-7ths and 13-8ths of its mass, or, perhaps, very nearly once and a half its mass or weight. The momentum, then, is equal to the sum of the weight and the product of the weight multiplied by once and a half the velocity per second, or $m = b + \frac{3bv}{2} = b + \frac{3b}{2}\sqrt{32s}$, where s = the space fallen through.

A monkey of 200lbs. weight falling 25 feet on a pile head will, therefore, strike it with a force equal to the weight of 200lbs. $+ \frac{600\text{lbs.}}{2}\sqrt{800} = 8{,}685$lbs. nearly; and a weight of 100,000lbs. falling one-hundredth of a foot would strike with a force equal to a pressure of 100,000lbs. $+ \frac{300{,}000\text{lbs.}}{2}\sqrt{0.01 \times 32} = 184{,}840$lbs.: or it will require a force of 184,840lbs. to lift 100,000lbs. one-hundredth of a foot, with the velocity of fifty-six-hundredths of a foot in a second. By the old formula of $m = bv$, which has been erroneously applied for m is as bv, this weight would be moved at the above rate by a dead weight of 56,000lbs, 44,000lbs. less than its weight.

I remain, yours obediently, B.

COL. C. W. PASLEY, C.B., F.R.S., &c., AND MR. GEORGE GODWIN, JUN., F.S.A.

[We have been requested to insert the following letter, addressed to Col. Pasley, in reference to the disputed point touching the first use of concrete in England.]

Sir,—Permit me, although personally a stranger, to claim your attention for a few minutes.

In your recently published and most valuable work, "Observations on Limes," you have honoured me by referring to an essay on concrete, for which the Institute of British Architects awarded their first medal in 1836: and in the course of your remarks have taken occasion to contradict a statement showing (if true) that concrete was used by the late Ralph Walker, Esq., at the East India Docks, in the year 1800, and to complain of the omission of the name of Sir Robert Smirke, to whom you, perhaps justly, ascribe the credit of having introduced the use of concrete in its present shape to this country.

When I commenced the essay in question, which was in 1835, I found materials for the attempt exceedingly scant and meagre. I was unacquainted with any modern work containing useful reference to the subject (at that time I had not met with your lithographed "Course of Practical Architecture"), and found few persons able to give me authentic information. Two or three distinguished architects, to whom I applied, and who since then have extended to me the favour of their acquaintance, declined affording me any particulars; and Mr. Ranger, known to have knowledge on the matter, refused positively, although with great politeness and some show of reason, to give me the slightest explanation of his own system, or the least item of information generally, so that I was compelled to trust for the most part to my own resources and observations. Under these circumstances I did not attempt to give to any one individual merit for its introduction, but, recording briefly such points in connection with this question as fell under my notice, passed on at once to treat of its composition and its uses, with an impression that what was said, would elicit such other information as might enable us hereafter to arrive at truth and fill the hiatus.

The assertion that concrete was used by Mr. R. Walker in 1800, was made, as you have seen in the essay, on the authority of Mr. Macintosh, the contractor, who, at the time I applied to him, was engaged in the construction of the Greenwich Railway. On the day that he related the circumstance (Oct. 5th, 1835), we were together directing the composition of concrete for the foundation of the archway over the Grange-road, Bermondsey, and the matter was so fresh in his recollection—was so far from a thing of doubt—that he allowed me to make notes as he proceeded with the conversation. These notes, Sir, I have sought for and found, and from them I see that Mr. M. said more upon the subject than I have printed—quite sufficient, indeed, to show that there was no misunderstanding on my part; and I beg leave, therefore, to copy for you one or two of his sentences, in order that you may judge for yourself. "I executed concrete," said he, "thirty-six years ago at the East India Docks. The ground was a mud bank, with here and there gravel and sand, affording, therefore, most unequal bearing; but the concrete has, nevertheless, answered admirably. I think this was the *first* time concrete was used in England, indeed I know it was. Trenches for outer walls were merely filed in with gravel, sand, and water, no lime, and this has stood well;" and he then went on to speak of the quantity of lime which he considered best, &c., &c. Upon this, then, Sir, my statement rests. I had no wish, nor the slightest motive to add to the reputation of Mr. Walker, still less, if possible, to withhold credit from Sir Robert Smirke, for whose talents (in common, I believe, with the profession generally) I entertain the highest respect and admiration. The information which has been furnished you, and which is set forth in your book, seems to show that Mr. Macintosh was mistaken, unless, indeed, the measure was determined on after the specifications were issued, and was adopted merely in some particular places by way of experiment; but as I have nothing farther to add on this head, I must content myself with affording the above explanation, and leave time to reconcile the apparently conflicting evidence.

In regard to the omission altogether of Sir Robert Smirke's name, of which you justly complain, I am bound to confess that I was not aware, at the time of writing the essay, that Sir Robert Smirke was more intimately connected with the subject than were several other architects also not referred to, although I knew well that he had used concrete in several places; in excuse for which want of information, I can only offer the circumstances mentioned at the commencement of this letter. Immediately after the publication of the "Transactions of the Institute," wherein the essay appeared, I learnt that Sir Robert Smirke *had* paid particular attention to concrete; and in a second edition, which closely followed the first, I introduced his name in a paragraph concerning the foundation of the Custom House; and later still—namely, in the second of a series of papers published in the "Architectural Magazine," and headed "Hints on Construction," I appended the following note to a remark, that "Ralph Walker, Esq., and Sir Robert Smirke, were among the first, if they were not *the* first, who employed concrete, and advocated its use in England," serving, I trust, to show my desire to correct the omission so soon as it was discovered. This is the note:—"The name of this distinguished architect (Sir Robert Smirke), in connection with the re-introduction of concrete, was omitted, through want of positive information in the essay on that subject, printed in the 'Transactions of the Institute of British Architects,' and the author of it seizes the opportunity here offered to rectify the error."

Here, Sir, I should have left the subject, as I felt it would be impertinent to thrust myself forward to state that on which, perhaps, no one might care to have my opinion, and knew that nothing which I could say, or omit to say, would increase or lessen the high reputation of Sir Robert Smirke. As, however, you have been pleased to draw attention to the circumstance in a book, which probably will be read universally, I feel called upon not only to render you this explanation, but to make it as public as circumstances may permit, lest any should imagine, were I silent, that I still saw no reason for connecting Sir Robert Smirke's name with the first use of concrete in its present shape in England.

I trust, Sir, that under these circumstances you will not deem me wrong or rude, for intruding at this length on your valuable time, but that you will accept my profound respect, and believe me, Sir, your faithful humble servant, GEORGE GODWIN, Jun.

Brompton, Nov. 26, 1838.

THE LONDON AND BIRMINGHAM RAILWAY.

The following account of the construction of the works in the neighbourhood of Blisworth, we have extracted from the fourth part of "Roscoe and Lecount's History and Description of the Railway," which we have before favourably noticed. Besides the usual illustrations, the present part contains a very useful map of the line of the country through which the railway passes, reduced from "Cheffin's Official Map."

This cutting is one of the largest on the line, and according to the original estimate, would have contained 800,000 cubic yards; in consequence, however, of the necessity which was found of adding to the length of the wide part of it, which was considered to be essentially requisite during the execution of the work, together with the materials arising from numerous slips in the upper part, the total quantity removed approximated to 1,000,000 cubic yards.

The greatest depth is about 55 feet, and the length a mile and a half. The materials excavated consisted of clay and limestone. The clay and rock may be described generally as running into strata nearly on a parallel with the line of rails, which rise from each end of the cutting towards its centre, at an inclination of 16 feet in a mile.

The different beds of rock in the excavation abound with fossil shells, in a good state of preservation, consisting of nautilus, terebratula, oysters, &c. There were also two or three fossils of very considerable magnitude discovered, which were of the Saurian tribe, and were found embedded in a stratum immediately on the top of the rock. This rock is a species of half-formed stone, of considerable hardness when dry, but becoming soon softened when exposed to the air and damp.

The quantity of stone excavated was about one-third of the contents of the cutting, and considerable difficulties occurred at this point of the line. The rock was found not to reach to the depth of the excavation, and underneath it lay a deep bed of clay, in some parts to the thickness of 20 feet, through which the rails had to be carried. To secure this from bulging out, it was necessary to build retaining walls of considerable thickness along the sides of the excavation, which are inclined at two slopes; that portion which reaches from the railway to the top of the rock is at one quarter to one, and for that above the rock the inclination is at two to one, a ledge or benching, of nine feet in width, being formed where the two slopes meet. The object of the benching is to catch any loose portions of the clay which might be detached from above; they have also been found very useful in affording foundations for walls of pebble-stone, which it has been found necessary to erect upon them in many places, to retain the numerous slips of the clay above.

Immediately below the solid rock, in some parts of the excavation, is a bed of loose shale, mixed with a considerable quantity of water, and to such an extent, that pumps had to be constantly employed to allow the work to progress. The shale has been taken out, and the rock underset several feet, to allow retaining walls of stone to be built in its place; these walls, in fact, support the rock above, and as a further security, an inverted arch has been built beneath the railway to the opposite side, in a similar manner to the inverts of tunnels. As soon as the retaining walls were built, a drift was formed behind them three feet six inches high by three feet wide, forming a culvert to receive the water, which still keeps abundantly flowing out of this strata; and at intervals there are openings left in the retaining walls to conduct the water to the side drains of the railway, where it is carried off.

During the first year and a half, the progress of this excavation was extremely slow, owing to the want of proper energy on the part of the contractor, combined with general bad management. The time was frittered away without anything like a proper quantity of work being done; and if this was evident at the commencement, when there were no particular difficulties to grapple with, what might be expected towards the end, when nothing but the most energetic measures could insure success? At last the Company were obliged to get rid of the contractor of the Blisworth excavation.

From the moment it came into the Company's hands, no trouble or expense was spared to remedy the evil of the previous slow progress; and nothing could exceed the animation of the scene which the works presented when in their most active state. From 700 to 800 workmen in vigorous employment, numerous barrows and waggon runs in continual motion, a steam engine in constant activity pumping out the water, locomotive engines at either end, dragging long trains of waggons full of earth, or bringing the empty ones back, and blasts of the rock continually deafening the ear. In fact, the whole cutting seemed alive; and the busy hum of labour, resounding from the one end to the other, gave ample testimony to the zealous exertions of the engineer. Of course the expense was considerable. The article of gunpowder alone was, in many cases, 25 barrels, of 100lbs. each, per week; enormous quantities being used before the rock could be removed.

The mode of blasting made use of was by drilling a hole in the stone, about one inch in diameter, the depth being determined by the thickness of the bed. This was done by means of a round iron bar shod with steel, which was lifted up and then struck down, in the hole, water being used with it to cause the stone to cut more readily, till the hole was drilled to the requisite depth. When sufficiently deep it was dried out; a piece of fuse of the requisite length was then put in, and the gunpowder poured all round it, and secured by a covering of pounded brick or stone. Several charges being thus prepared, the ends of the fuses were lighted, and the workmen retreated to a sufficient distance for security. In a few minutes the whole exploded, rending up large masses of rock, and sending the lighter pieces high into the air.

This excavation is crossed by five bridges, some of which are of considerable span, and presents a fine appearance from the railway. They are composed of a mixture of the stone of the cutting and brickwork. It was originally intended that the whole of the materials which came out of the excavation should be used in the formation of the embankments at each end of it; but owing to the slowness with which the work advanced while under the contractor's hands, it was found necessary to throw about 150 000 cubic yards into spoil. The land for receiving this, together with that necessary to make up the corresponding deficiency in the embankments, of course still further increased the expense of the work.

The stone, gravel, and clay which were taken from the south end, had to be conveyed an average distance of about a mile and a half, and considerable difficulty was found in the formation of the embankment near the village of Ashton, owing to the unsound state of the valley which formed its base. Immense quantities of materials were teemed daily, which, as in the case of the Wolverton embankment, totally disappeared, and the natural surface of the ground actually burst up outside the limits of the railway, in consequence of the enormous pressure. A culvert near the spot was entirely destroyed from this cause.

The embankment at the north, or Birmingham end of the excavation, has more earth in it than the other; but the substratum on which its deepest part rests is of a better description, and no slip of any importance took place in that portion of the works; but a culvert of considerable length was in great danger of being crushed in; the expedient, however, of completely filling it with pebble stone was resorted to; notwithstanding this precaution, it was carried considerably out of its straight direction, so much so, that the light can but just be perceived when it is looked through. It may, perhaps, be thought uninteresting to mention works of so small a magnitude as culverts; but no person, who has any knowledge of the difficulty of their erection, when they have to sustain the weight of an embankment of 40 or 50 feet in height, could feel otherwise than nervous during the process of placing the material over them. An engineer could be wished no worse fortune than to be required to construct culverts upon a soft foundation under a deep embankment.

From this view of the nature and extent of this contract, and the means which were resorted to, in order to make up for the serious delay which occurred while the work was under the contractor's hands, every body will be prepared to expect that a sum of nearly 100,000l. has been expended beyond the original estimate; and been expended wisely, too, as the loss would have been considerably greater if these exertions had not been made. Viewing the work altogether, it affords one of the finest specimens of engineering this country can boast of. It is a spot beset with difficulties of every kind, and the bold and effective manner in which it has been executed, is a bright example of the talents of the Engineer-in-Chief.

PAPIER MACHÉ ORNAMENTS,

For the Actæon, Liverpool and Glasgow Steam Ship.

We have been favoured, within the last few days, with an inspection, at the manufactory of Messrs. Jennens and Bettridge, of a set of panels, in *papier maché*, intended for the decoration of the Actæon, Liverpool and Glasgow steamer; which, as works of art, have not, we believe, been surpassed by anything of the kind ever produced at this celebrated establishment. The panels are 28 in number, four of which are very large, and consist of historical subjects, some original, and others copies from the works of celebrated masters. The first represents, the triumphal entry of Alexander into Babylon; the second exhibits a view of a Grecian sea-port, and the arrival of a victorious fleet; the third describes the Olympic games, the combats of gladiators, &c.; the fourth gives a representation of the Hippodrome, the temple of Victory, and chariot races. Each of these subjects is depicted by the artist with the vividness and freshness of life. The various groups of Grecian, Egyptian, and Persian figures, the richness and brilliancy of the costumes, the colossal statues, temples, and columns, in their architectural grandeur and beauty, furnish a vivid representation of the barbaric pomp and magnificence of bygone ages. The smaller panels are divided into the classes, devoted to the illustration of particular subjects. The first series represents full-length figures, emblematic of Victory, Commerce, and the Arts and Sciences, surrounded with beautiful ornamental work, drawn in imitation of *alto-relievo;* the whole surmounted with the arms of Liverpool and Glasgow. The second embraces mythological subjects, representing the triumph of Neptune, Juno, and the Graces, Actæon, &c.; the whole adorned with an emblematic framework. The third comprises mosaic heads, and emblems ornamented with arabesque foliage, birds, flowers, and fountains. Viewed separately, each of these paintings is an exquisite specimen of the advanced state of this department of our manufactures and the fine arts; and, as a whole, they form unquestionably one of the most unique and splendid collections of the kind ever produced. The panels will not, we believe, be removed for a few days from the show-rooms of the manufactory, where artists and other visitors may have an opportunity of inspecting them.—*Birmingham Herald.*

PRUSSIAN RAILWAY.

The *Prussian State Gazette* publishes the text of a *law for the regulation of railway companies in the Prussian dominions.* It consists of 49 articles, and is framed in such a manner as to guard the public as much as possible from the speculation and jobbing to which undertakings of this nature are so liable to give rise. Among the more essential stipulations which it makes with this object in view, it provides, that while the shares may be made payable to bearer and free from stamp duty, no promises of shares before the undertaking of a railway is authorised, nor provisional acknowledgments are to be issued. Every subscriber for shares is to be bound personally to pay 40 per cent. of the nominal capital subscribed for by him, and he cannot get rid of this obligation in favour of a third person or of the company, under any pretence whatever. In case of a railway not being terminated within the time fixed in the grant of privilege, the government is to have the power, after a delay of six months, of ordering the road to be finished by public contract, at the charge of the company. The privileges of the post establishment may be exercised by railway companies under certain conditions. Railways are to be charged with an impost proportioned to the amount of the reserved fund of the company, but only after the railway shall have been opened three years, and that the state of its returns admits of it, and no other taxes are to be laid upon it. This impost is to indemnify the state for the diminution of revenue caused by the railway in the post department, and to form a sinking fund for the paying off the capital employed in the construction of the road. The state reserves to itself the right of purchasing the railway after a lapse of 30 years, on paying to the company 25 times the amount of the mean annual divideud received by it during the last five years of the 30, the state at the same time taking upon itself the liabilities of the company, but becoming absolute owners of all its property, including the reserved fund. No grant of a rival line can be made for the first 30 years; but after the first three years other companies may acquire the right from the state of conveying passengers and merchandise by the same line, on paying a fixed rate of charge to the original company. One of the concluding stipulations of this law is, that no damage occasioned to the railway by measures adopted, even by order of government in time of war, is to be paid for by the state. This law affects all grants of railways already made, as well as those to come.

OXFORD-STREET EXPERIMENTAL PAVEMENT.

The importance of ascertaining the best species of pavement for the carriage-roads of the metropolis is some excuse for the confusion, accompanied by the smoke and offensive odours from the cauldrons, which have prevailed at the east end of Oxford-street for the last two months. The inhabitants have, however, been great sufferers thereby; but we may now congratulate them that, at last, all the ground is assigned and set out for the different varieties, while many of them are completed, and the rest are in progress. Commencing at Charles-street are the *asphaltum blocks of Robinson,* one half laid straight, the other diagonally. This is followed by *granite pavement* nine inches deep, jointed with Claridge's asphaltum; then is to succeed a granite pavement of stones only 4½ inches deep, also to be joined with the same substance, Mr. Claridge being of opinion, and desirous of proving, that his cement is sufficiently strong to bind even these shallow stones into one solid mass. To this succeeds the *Bastenne Company's* portion; the blocks in this part are in the form of bricks, but somewhat larger; they have been laid both ways, straight and diagonally. Next follows the *granite pavement,* laid by the parish, which is undoubtedly one of the finest specimens of work of its kind to be found in London. It consists of three parts:—1. Stones laid in the ordinary way, on a well-formed bed of concrete. 2. Similar stones laid diagonally on a bed of the same material; the joints of both these portions are filled with a grouting of lime, sand, &c. 3. Stones laid in the usual manner, but on the earth without any official bed, and the joints are filled in with fine gravel. The whole of this work has a good curved surface, and the regular thickness of the stones has evidently been carefully attended to. The next experiment, going towards Tottenham-court-road, is what is called the *Scotch asphaltum granite* (said to be a patented article). This composition has the appearance of stone, and the blocks are about six inches thick, nine inches broad, and 18 inches long on one face, while the other is only 13 inches long. In laying them (which is done with Parker's cement), every alternate block is reversed, so that every second block lies solid on its base, or longest face, while the others fit in between them as keystones, and, when joined, each may be said to support the other. The next division is the *wood pavement*, composed of blocks of fine timber Kyanized, they are of a hexagonal form, 7 inches diameter and 15 inches deep, part is laid on a bed of 1½ inch planks. Then follows the *Val de Travers Asphalte*, which will occupy the remaining portion of the street devoted to the experimental pavement. This last article consists of blocks, about 10 inches square and five inches thick, formed of a bitumen thickly studded by broken pieces of granite; so that, when laid, it may be looked upon as a sort of Macadamised road, where, in lieu of earth for filling the interstices between the broken granite, and making the whole of a solid mass, a strong binding composition has been employed.

MONUMENT TO DR. VALPY.

A committee of the pupils and friends of the eminent classical scholar, Dr. Valpy, being desirous of testifying their esteem for his memory, have employed Mr. Samuel Nixon to execute a statue of him. The statue is of stone, from the quarries of Roche Abbey, Yorkshire, and represents the Doctor, the size of life, in a standing posture, and draped in the robes of a doctor of divinity. The sculptor had not the advantage of seeing the Doctor during his life, but he has been able to avail himself of a bust by one of the Westmacotts, and of a portrait by Opie, so as to give a satisfactory likeness. At the same time he has been freed from those conventional and habitual trammels by which friends and relations too often distress the artist. The figure and drapery are formed with ease, and their details are carefully executed, and altogether it is a work by which the subscribers may feel gratified, and Mr. Nixon honoured. It is intended to be placed in the parochial church of St. Lawrence, at Reading; but this site seems by no means to meet with the approbation of the press, so that the subscribers may, perhaps, be induced to give it a more public destination.

STEAM SHIP "LIVERPOOL."

The voyage of this steam vessel to New York appears likely to throw some light on the subject of the most judicious means of economising fuel. In the first unsuccessful attempt of that vessel, she appears to have consumed hourly a very large quantity of coal beyond what had been the estimate of the engineers; and to which circumstance was attributed her return to Cork. The cause of this extraordinary expenditure of fuel will be hereafter worthy of consideration, as it may lead to some valuable information.

On her voyage from Cork to New York the following facts have been elicited. The voyage occupied 16 days 17½ hours, during which time 464 tons 17 cwt. of coals were consumed, being about 23¼ cwt. per hour, and which was less than the engineers had, in the first instance, calculated on. On her first starting from Liverpool she had, it appears, 563 tons on board, of which 350 remained when she put back for Cork. One remarkable feature in the economy of steam, and of course, of fuel, appears to have been the use of the expansion-valves, and which varied from 42 to 24 inches. The application of these expansion-valves, from some hitherto unexplained cause, were not brought into operation on the first unsuccessful voyage on any occasion. The following extract from the log wi l show what an important feature these valves, and the means of using steam expans.vely. present on long voyages:—

Extract from the Log of the Liverpool, on her voyage from Cork to New York.

	Fuel consumed. T. C. Qrs.	Hours.	Miles by observation.	Daily average expansion.
Nov. 6	3 2 2	24½	20	42 Inches
7	29 18 0	24	180	41

	Tons 464 17 2	423½ Hours	3156 Miles	

The engines of the Liverpool are of the largest power yet in use, being 467 horse power, diameter of cylinder 75 inches, and length of stroke 7 feet or 84 inches; considering that the greater part of the voyage was under circumstances of tremendous head seas and gales of wind, the daily consumption appears a fair one.

Since writing the above the Liverpool has returned to England. She departed from New York on the 6th, and arrived at Liverpool on the 21st of December. She steamed 3239 miles in 348½ hours, and consumed 445 tons 9 cwt. of fuel, and had remaining, when she reached Liverpool, sufficient fuel on board for 11 days more, or 2456 miles additional distance.

THE BANN RESERVOIRS, COUNTY OF DOWN, IRELAND.

MR. BATEMAN, ENGINEER.

The river called the Upper Bann, is peculiarly liable to great irregularity in the quantity of water; presenting, sometimes almost a dry bed, while, at others, floods are pouring down with destructive violence.

The principal mills and bleach works are situated near the town of Banbridge, where the river is closely occupied, above and below the town, for about ten English miles.

Very considerable inconvenience was occasioned, during the summer months, and other dry seasons of the year, by the inadequate supply of the river; and, to remedy this inconvenience, it was proposed to construct reservoirs.

The greater part of the merchants and land proprietors connected with the district, having formed themselves into a body, in the spring of 1835, instructed Mr. Fairbairn, of Manchester, to examine and report on the most favourable sites. Three sites were, consequently, fixed upon—Lough Island Reavy, near Castlewellan and the Deers' Meadow, near Hilltown, as impounding reservoirs; and Corbet Lough, a few miles above Banbridge, as an auxiliary reservoir. A bill was brought into Parliament, which received the Royal assent, on the 4th of July, 1836, empowering the company to raise 40,000*l*., in 50*l*. shares, and to levy a rate on each foot of occupied fall, not exceeding 10*l*. per annum, the interest of the money expended being limited for the protection of the fall-holders, to 7½ per cent. per annum.

The construction of the Lough Island Reavy reservoir, the largest and most important of the three, has been carried on with vigour, and is now nearly completed. This, before the construction of these works, was a natural lake of about 92½ statute acres; but the area of the reservoir will be about 253 statute acres, the surface of the water 35 feet above the level of the old lake, and the average depth of the whole about 27 feet. It will be capable of containing upwards of 290 millions of cubic feet of water, and will keep up the water of the river, during the whole year, at about six or seven horses' power to each foot of fall. The construction of the Corbet Lough reservoir, by saving the night water from Lough Island Reavy, or that portion which would be running past the mills, when they were not working, would increase the power of the river to nine or ten horses' power, upon each foot of fall, below the outlet, from Corbet Lough.

The land, for the Lough Island Reavy reservoir, including the value of some chief rents, payable by the company, has cost about 6,000*l*.; and the expense of constructing the various works—viz., embankments, feeders, roads, &c., will amount to between 14,000*l*. and 15,000*l*.

There are four embankments to retain the water in the reservoir, measuring together about 1,560 yards in length, and containing about 219,000 cubic yards of earth and stone work. The principal bank is 700 yards long, and contains about 112,000 cubic yards. The inside slopes are faced with stone pitching, varying from two to three feet in thickness, according to the sheltered or exposed situation of the banks. They are formed in concave horizontal layers, about three feet thick, with an upright "puddle wall" in the centre.

The water is discharged by two cast-iron pipes, of eighteen inches in diameter, within an ashlar granite culvert, extending under the principal embankment, the valves being at the outer end, and enclosed in a handsome vault or building of the Egyptian style of architecture.

To supply the reservoir, the river Muddock is directed into it by a feeder, or new river course, 1 mile 550 yards in length, 4 feet 6 inches deep, 19 feet 6 inches wide at the top, with stop-gates and waste weirs to regulate the quantity of waters. The surplus waters of the Moneyscalp brook, and of the Slievenalargy brook, are also taken into the reservoir; the first by a feeder of 1,060 yards long, and 3 yards wide; and the latter by a drain of about a quarter of a mile in length.

To convey the water from the reservoir to the river, the old drain from the Lough to the Muddock, about a mile in length, has been made 5 yards wide.

The reservoir, when full, will be one and a quarter English miles in length, half a mile across in the broadest part, and near a quarter of a mile in the narrowest and, with the assistance of a little judicious planting, will present one of the most interesting objects in that part of the country.

PROCEEDINGS OF SCIENTIFIC SOCIETIES.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

The first meeting for the present session was held on Monday evening, 3rd December, Earl de Grey, president, in the chair.

The noble president, on taking the chair, expressed his satisfaction at meeting the members on that occasion, and briefly alluded to the circumstances which had transpired since the last session. During the recess an attempt had been made to consolidate this society along with another formed for the prosecution of similar objects, but without success. Since they had last met the profession of architecture had lost one of its most distinguished members in M. Passier, a foreign corresponding member. To show the reciprocity of feeling and spirit which existed between the architects of our own and foreign countries, it was stated that the intimation of his death was officially communicated to the society. Another instance of the growing interest and importance attached to the institute was also recently shown in the case of the visit to this country of M. Zant, a foreign professor, who made it his depository. During the recess the council have made arrangements for the delivery of lectures on acoustics and geology, two important objects connected with architecture, and which will soon be delivered. It is also intended to enlarge the benefits of the institute by establishing a new class, to be called the students' class, for the instruction of those who are not forward enough for associates.

Mr. Donaldson announced the list of presents received since the last session, and stated that the noble president had communicated with the Rajah of Tanjore, to whom the institute is under so many obligations, to continue an intercourse which has already been so beneficial.

Mr. Barry exhibited various medals taken out of the excavations for a sewer near the site of the new Houses of Parliament, a description of which was promised on an early occasion.

Mr. Fowler read a highly interesting paper on the art of glass painting, by Mr. Shaw, member, entering at length into its antiquity, general divisions, classification, different styles, and proper employment.

Messrs. Hoadley and Oldfield, of the Hampstead-road, exhibited some beautiful specimens of stained glass.

Mr. Godwin, jun., presented to the meeting an engraving of Girard College, Philadelphia, now in progress of execution, together with the original drawing, which had been left with him by the architect, T. Q. Walters, Esq., for that purpose. Mr. Godwin did this personally, in order that he might inform the meeting of the great respect with which the Institute was regarded by the American architects, and of the endeavours which had been made to form a similar society there. Widely separated as the States are, circulars were addressed to the chief architects in each, inviting them to attend in New York on a certain day, for the purpose of organizing an association; and several of the instigators of the attempt travelled a hundred miles to keep the appointment. The meeting was more numerous than could have been expected. Resolutions were passed, rules drawn up, and then, having first arranged an annual re-union, they each departed to their widely-separated homes. The second meeting, it need hardly be said, when the difficulties are considered, was less numerously attended. The chief members of the society, who were much engaged, found the sacrifice of time too great, and the attempt was ultimately given up, although not before much good feeling had been promoted, and some other good results effected. As Mr. Godwin observed, the whole transaction was so creditable to our Trans-Atlantic colleagues that it was worthy of mention at the Institute of Architects.

The second meeting for the session was held Monday evening, 11th December, Mr. Robinson, V. P., in the chair.

Mr. Godwin, jun., read a letter in explanation of some published views of his upon concrete, and in reply to some remarks on the subject by Colonel Pasley.

The donations to the library contained several works of rare archaiological and architectural interest; and amongst various novel objects exhibited were some drawings of the Cathedral of Carlisle, and in particular of the circular roof, from Mr. Billings; some very superior embellishments and designs in paper-hangings, from Mr. Clark; and a French work from Mr. Bohn, on the antiquities of Mexico, being a continuation of the splendid work of Lord Kingsborough on the same subject.

Mr. Donaldson, the secretary, read a memoir of the late Mr. Thomas Lee, architect, who died in 1834, and who was one of the founders of this institute. He was engaged in the construction of a great many public works, the most prominent of which was the column to his Grace the Duke of Wellington, erected on Wellington-hill, one mile and a half from Blackdown, in Somersetshire, and near the place from which the title is derived. After a very successful and eminent course, this deserving architect was found dead on the shore, near which he had been bathing, near Exeter, meeting an untimely death at the age of 40 years.

An interesting conversation ensued on the subject of the various combinations of the different orders of architecture, on which the probable opinion was given of the formation of an English style, of which there are now so many proofs.

ARCHITECTURAL SOCIETY.

At an ordinary monthly meeting of the society, held at their rooms, No. 35, Lincoln's-inn-fields, on Tuesday evening, Dec. 4, 1838, William Tite, Esq. F.R.S., President, in the chair, a letter was read from Mr. Sims, on various uses of asphalte, which the writer did not, however, consider applicable to ornamental structures, from the ease with which it was affected by heat, from the sun, and other causes. A notice was given that the next subject for a sketch was a design for an entrance to a railway station, without offices. Mr. Phillips read an interesting essay on some essential points connected with structure, which we have inserted in another part of our journal.

The following letter was inadvertently omitted to be forwarded last month, but which was received some time since from the Architectural Union at Berlin, and read at the opening meeting.

TO THE ARCHITECTURAL SOCIETY, LONDON.

The Architectural Society have received our friendly greeting, which Mr. Alexander undertook to deliver. We herewith beg to repeat the same, and likewise to express the wish that, by means of interchange of information, with a view to the promotion of our art, we may cement an intimate connexion between the two societies.

We observe by the laws of the Architectural Society, which Mr. A. presented to us, that, with some variation in form, the society has the same object in view, and consists of similar members to our own. We believe, therefore, that each society may be benefited by reciprocal communications, and accordingly beg that we may be entrusted with inquiries and commissions within the sphere of our profession, and that we may be permitted to use the same freedom.

With the laws of our society we beg herewith to present the first number of the Architectural Album, which is not the work of the members of our society alone, like the architectural designs, but of German architects generally, and which, by means of details, individual buildings, and construction, may be also useful to the workmen.

We purpose sending the continuation of this work, as well as the designs from the collection of the Architectural Union, together with the appertaining letter-press, and we beg your friendly acceptance of the same.

With high respect,

THE COUNCIL OF THE ARCHITECTURAL UNION, BERLIN.

SOCIETY OF ARTS.

The ordinary meeting was held on Wednesday evening, 19th December, David Pollock, Esq., vice-president, in the chair. The silver medal was balloted for, and awarded to Mr. J. Gray, for an improved instrument for taking out teeth and stumps from their sockets. The arrangements allowed of a greater facility for its introduction, and upon extra claws which allowed of freer purchase upon the stump. A letter was read from the secretary of the East India Company, accompanying a sample of tea from Assam for the opinion of the society. A silver medal was next voted to Mr. H. Page, for an improved, easier, and more durable method of lettering marble. A communication was read from Mr. George Aikin, on the recent agricultural improvements in the fens of Cambridgeshire. The natural soil of these parts is dark, being almost gray, and is mixed with a quantity of silt, below being a spongy peat, and great part being on a stratum of blue calcareous clay. The Bedford level, comprising 300,000 acres, was formerly very subject to overflows, and it was only possible to work the land in spring and summer. The greatest quantity of oats that could be procured was from four to five quarters per acre, and the crops were often lost by the floods, but now, owing to improved agriculture, principally resulting from the application of steam power for windmills in drainage, the produce was from five to eight quarters. One great improvement was in the introduction of clay or marl, and where formerly only bad oats grew there could now be obtained excellent crops of good wheat and oats. The proportion and succession of crops were stated, and the thanks of the society were voted for the communication. Communications were next read from Mr. Roberts and Mr. Hickson on the growth of a new variety of potato, submitted to them by the society in January last, but which were referred back for further experiments. The meeting then adjourned over the recess to the 9th of January.

ARTISTS' AND AMATEURS' CONVERSAZIONE.

The first conversazione for the season of this valuable society took place on the 5th Dec. last, at the Freemasons' Tavern. We cannot expect many visitants at this early period of the season, but we were pleased to see it so well attended. There were perhaps not so many publishers present as on ordinary occasions, and fewer novelties, as to engravings; but this deficiency was well supplied by the general interest in the proceedings which seemed to animate the company. Among the engravings was one in the line style, by Robert Graves, A.R.A., from the picture of Shakspeare, taken before Justice Lucy for deer stealing. It does equal honour to the engraver, and to Mr. George Harvey the painter. An additional point of interest attached to this work is that the room and its furniture are studies, by permission of the descendants of the Midas judge from the objects now in their possession. The picture and engraving both belong to the Scotch Association. There was also a picture by Allen, of Whittington and his cat, and another by Cooper, and also an engraving of the Battle of the Covenanters at Drumclog. Stanfield contributed several drawings, and among the minor objects were a portrait of Miss Roberts by Mr. John Wood, a miniature, copied from Gainsborough, by Miss Augusta Cole, and nautical sketches by D. Serres, &c. We were glad to see the ladies come forward to support those elegant arts which instead of meriting the designation of Pliny, "Solatia servitutis," ought more properly to be considered as ornaments of the household, and handmaids of the domestic virtues. As the season advances these conversazioni will, no doubt, be more fully attended by the numerous members; but even at the present early period they afforded full evidence of the pleasure they were capable of communicating, and the good they are likely to effect. It is, indeed, through such means that artists must hope to promote the progress of the Arts, which are no mysteries to be kept secluded, nor objects of difficult comprehension, but as they appeal strongly to the human mind, so by that they must be judged, and to be admired they must first be known.

HORTICULTURAL SOCIETY.

At the ordinary meeting on the 4th instant, Dr. Henderson in the chair, Dr. Lindley read a lengthened report of the effects of the late frost of 1837-8. The intensity of the cold was much greater than in many previous years. It had been proved, notwithstanding the assertion that the ground had been frozen to a depth of two feet, that although on the surface the thermometer was four degrees and a half below zero, it was never frozen for a foot below the surface. In the kitchen ground the frost was not found at more than nine inches, in ordinary soil at ten inches, and in an arboretum of moss not below five inches. The concluding part of the paper was devoted to an examination of the mechanical and other effects of frost upon plants.

MEETINGS OF SCIENTIFIC SOCIETIES.

Royal Society, Somerset House, Thursdays, at 8½ P.M., 10, 17, 24, and 30.

Society of Antiquaries, Somerset House, Thursdays, at 8½ P.M., 10, 17, and 24.

Institution of Civil Engineers, 25, Great George-street, Westminster, Tuesdays, at 8 P.M., 8, 15, and 29.

Royal Institute of British Architects, 16, Lower Grosvenor-street, Mondays, at 8 P.M., 7, and 21.

Architectural Society, 35, Lincoln's-inn-fields, Tuesday, at 8 P.M., 1.

Society of Arts, Adelphi, Wednesdays, at 8 P.M., 9, 16, 23, and 30.

LAW PROCEEDINGS.

ALLEGED BREACH OF CONTRACT.

The following case, relative to contracts, is so important to the profession, that we recommend it to their especial notice:—

VICE-CHANCELLOR'S COURT—Dec. 7, 8.

RANGER v. GREAT WESTERN RAILWAY COMPANY.

Mr. K. Bruce, Mr. Jacob, and Mr. Stevens *appeared on behalf of the Great Western Railway Company, in support of a demurrer put into a bill, which the plaintiff, who is a large contractor with the company, had filed against them, to obtain relief under certain contracts he had entered into with them, principally with reference to works at the Bristol end of the line.* The learned counsel said the demurrer had been filed on two grounds—multifariousness and want of equity. Before reading the prayer, however, it would be necessary to give the court a short outline of the case on which it was founded, as well as to make the alternatives it contained intelligible to the court. The plaintiff, William Ranger, had entered into four contracts with the company for the prosecution of works on various parts of the line. The contracts known in the pleadings by the letters B 1 and B 2, and the supplemental or extension contract, all related to portions of the works on the Bristol end of the line. They were not connected together, but all had reference to a neighbouring district of the country. The fourth contract, distinguished in the pleadings as L 8, from its relating to the London end of the line, referred to works in the neighbourhood of Reading, and was materially distinguished from the other three. In the course of making these contracts the plaintiff found it necessary to obtain sureties to join with him in his contracts with the company. The sureties to the three first contracts were James Cordy and Richard Ranger only, and to the last James Cordy, Richard Ranger, and George Ranger. These sureties and the company were the defendants to the suit. The contracts contained provisions similar to those which were familiar to the court, from having occurred in the Popish chapel case at Hereford,* where the contracting parties submitted to refer every dispute as to the sufficiency of the work to the decision of the architect. The only difference in this case was that the superintending engineer, instead of the architect, was to be the absolute judge of the fitness of the work, and as to the payments to be made from time to time on certificates under his own hand. Nothing could be more absolute than the powers given by these provisions; they were, nevertheless, generally adopted in contracts of this description, and though it might excite some wonder how parties would willingly submit themselves to them, still they had not yet been found in practice to be ordinarily attended with inconvenience. Independently of this power the contract contained a stipulation that the company should be empowered to resume possession of the works, in case the plaintiff made any default in its execution. Under the provisions of this contract the works had proceeded from time to time to a very considerable extent, when, after various disputes and defaults (as the company alleged) on the part of the plaintiff, the company at length, in exercise of their powers, had taken possession of the plants, works, materials, &c., which were situate in that part of the Bristol end of the line comprehended in the contracts B 1, B 2, and the extension contract. Of the works comprised in the other contract in the neighbourhood of Reading possession had not been taken, but they were now in progress and diligent prosecution by the plaintiff. This brief abstract of the case would enable the court sufficiently to understand the prayer of the bill, with this additional observation. In the course of the works the company, at Ranger's request, made payments to him which, as they represented, exceeded the amount of what was justly due to him, whereon they took certain security on the plant, materials, &c., as a kind of mortgage, without taking possession, and of the reserved funds of 20 per cent. in the hands of the company. These matters being all fully set out, the principal portions of the prayer were that the company might elect whether they would permit the plaintiff to continue and complete the several works which on the 2nd of July last he was in the course of completing, or whether they would discharge the plaintiff from the further execution of them, the plaintiff offering to accept either alternative, on being paid the amount justly due to him on the footing of his contracts and agreements, or otherwise on such terms as the court should think fit to direct. And in case the company should elect to permit the plaintiff to continue and complete the works, then that they might be directed to reinstate the plaintiff in the possession of such of the works and of the plant and materials thereon, of which they had taken possession, and to pay him such amount as, upon a just account to be taken as after prayed, should be found to be justly due to

* Reported in Journal No. 8, p. 201.

moneys paid to him or for his use, and all moneys which the company should be entitled to deduct or retain by way of a reserve fund or under their mortgage deeds or otherwise, during the progress of the works, and that all proper accounts might be taken for ascertaining such balance, and that all proper directions might be given for ascertaining the quantity and price of the contract works. And in case the company should elect to discharge the plaintiff, then that he might be wholly and completely exonerated from all future liability to see to the execution of the works, and from all responsibility to arise therefrom; and that thereupon all accounts in relation to the contract and works, or such of them from which the plaintiff should be discharged, might be taken, and that the company might pay the balance, deducting therefrom the amount due on the footing of their mortgage securities, the plaintiff offering, in case a balance should be found due from him, to pay the same, and that the company might be decreed to deliver up to him the plant, engines, &c., of which they had taken possession, and permit him to remove that portion of which they had not taken possession; and that it might be declared the plaintiff was not subject to or was entitled to be relieved in equity against any penalties or forfeitures under his contracts; and that the company might be restrained from retaining or withholding from the plaintiff the possession of his plant, &c., of which they had taken possession, and from doing any act whereby he might be prevented from completing the works or from removing off the ground, or otherwise altering the situation of the plant and materials already upon the ground. The court would thus see the relief prayed turned upon the right of the company to make their election which course they would take, no offer being made to redeem the mortgages, nor any question of account raised, except on this imaginary right to have an election. He should now proceed more in detail with the case made upon the bill. It set out with a statement of the act of Parliament of the 6th of the late King, incorporating the company, and setting forth their powers, under which any three directors might enter into written contracts, which would be binding on the company. It then stated subsequent acts under the several provisions of which, taken together, they had entered into the four contracts with the plaintiff, which it was alleged were signed by the plaintiff, and under the common seal of the company, or otherwise executed on behalf of and assented to by them. The first contract (B 1), dated March, 1833, related to the erection of earth work, tunnelling, building a bridge over the river Avon, &c., stipulated the works should be done to the satisfaction of the company, and of their principal and resident engineer, clerk of works, surveyor, and inspector, and declared that all disputes were to be referred to the exclusive arbitration of the principal engineer for the time being, and the instalments for works done were only to be paid on a certificate under his handwriting. It then contained the usual powers to the company, requiring a sufficient number of workmen to be employed, and preventing sub-contracts without the consent of five directors. Then followed a clause, that in case the contractor should become bankrupt or insolvent, or should neglect or otherwise become incapable to proceed with the works, the company should have power to give him notice in writing to proceed, and if default was made for seven days after such notice, the company were at liberty to employ others to proceed with the works, and any previous payments were to be considered as the full value of any works already done.

With reference to the nature of the engagement into which the defendants had entered, they were found to exist in all trades and professions. The direction being absolute, the company had taken possession on a breach of the contract, and, if they had taken wrongful possession, an action of trover or ejectment was the proper proceeding. The learned counsel concluded by observing that no fraud was alleged either against Mr. Brunel or the company. The plaintiff only disagreed with Mr. Brunel on questions of time and other calculations: he only attacked his skill, or accused him of negligence, but nowhere complained of fraud. In one place he said he was unfairly dealt with; and, as it had been decided in the Hereford case a charge of fraud was necessary, and was nowhere to be found in the present, it could not be relieved against in a court of equity. On all these grounds, therefore, the demurrer must prevail.

Mr. Sergeant Wilde, Mr. Wakefield, and Mr. Girdlestone, severally addressed the court in support of the bill. The learned counsel dwelt upon the importance of the case to the plaintiff, whose property, to the value of 100,000*l.*, was arbitrarily seized by the company, and himself left to the mercy of his creditors, whose money he had expended in purchasing that property. The contract, it was contended, was so manifestly unrighteous, and the use made of it was so unjust, that the court was bound to interfere. The plaintiff contended there was no forfeiture. The company, it was charged, was labouring to create one by inequitable means, and this manner of acting, both prior and subsequently to the notice, bore out the imputation of the fraudulent motives which dictated the notice; and when the plaintiff was earnestly praying for some specific information as to the causes of complaints, the defendants were as cautious in concealing them. Upon the point of multifariousness, the decisions of the present Lord Chancellor showed that was a question of convenience, and the company, at least in this instance, had no reason to complain that one bill, rather than four, had been filed against them.

During the discussion, which occupied the whole day, his Honour asked whether the validity of such contracts of forfeiture as these had been discussed in courts of law?

Mr. Sergeant Wilde did not recollect any instance in which the question had been tried.

him, under the contracts or otherwise in respect of the contract works and extra additional altered works and extension works, after deducting all

His Honour said this was a case very much parallel to that of the Roman Catholic chapel at Hereford, where the whole works were seized, and the contractors were left to get what redress they could; and certainly they got none in this court. It was a case of heart-breaking hardship, but his Honour never heard there was an appeal from his decision.

Mr. Sergeant Wilde—Probably the men became bankrupt.

When it was urged by Mr. Wakefield that the principle of law would not permit the parties to constitute Mr. Brunel a judge without appeal,

His Honour asked, then what would become of the case of Heap *v.* the Archbishop of Canterbury?

Mr. Wakefield relied on the well-known rule as to arbitration clauses.

His Honour, without calling for a reply, delivered judgment, and said he must allow the demurrer for want of equity. He did not think the objection for multifariousness was well founded, or the contracts, though not one and the same, were yet in *pari materia*; and if the court had jurisdiction at all, it could only exercise that jurisdiction upon the contracts altogether, and the parties had, in their dealings under the contracts, blended them together, according to the allegations in the bill. One observation, however, occurred to him: the suit was so framed that if any other parties should make the objection, it can hardly be made without producing that objection to the bill for want of parties which the plaintiff had already submitted to as insuperable. It was impossible not to see that George Ranger had nothing to do with the three first contracts, and if he objects, his name must be struck out of the record; and if he is off the record, the objection for want of parties revives, and thus the bill is placed between Scylla and Charybdis. With respect to the general point, he could not but himself think it was the intention of the company that they should have, in a very great degree, an arbitrary power to dismiss the contractor if they should feel dissatisfied with him; and, to his mind, the language of the clause which related to the notice of dismissal proved it. The clause was thus:—"In case William Ranger should become insolvent, or be declared a bankrupt, or from any cause whatever other than the act of the company, their engineer, or agent, should be prevented from, or delayed in, proceeding with and completing the work according to the contract, or should not commence or proceed with the work to the satisfaction of the company, then it should be lawful for the company to give him notice, requiring him to enter upon and regularly proceed with the work; and in case he should, within seven days after the notice, make default, it should be lawful for the company to employ another respectable workman," and so on. His Honour observed upon the generality of the second member of the sentence, namely, "in case the contractor should not commence or proceed with the work to the satisfaction of the company," and said it appeared to him that the parties in forming the clause were sensible if they allowed it to stand in the spirit of the first member of the sentence they would have taken away from the company their arbitrary power; and if they meant to guard against a despotic and arbitrary exercise of power or whim, how came it that none of the exceptive words in the first branch found their way into that sentence? And it appeared to him that there was very great reason for the company to stipulate for that power, for these works must be performed in a particular time, and it would never do for the company to enter into bickerings with the contractor from time to time whether he was going on with the works in a proper manner; and, therefore, in his opinion very wisely, and with the full knowledge of the contractor, they stipulated for an arbitrary power to give notice; and he could not but think the only reasonable method of construing the words "make default" was to read them with reference to the preceding sentence, so as to make the dismissal to depend simply upon his not going on to the satisfaction of the company. Any other interpretation would be nonsense; for, suppose the company gave notice, and the contractor went on to their dissatisfaction, they must, it is said, give notice again; and so on you have a succession of notices, and the company in a perpetual state of dissatisfaction with the contractor. That could not be the meaning of the parties. It was evidently their intention that that the company should have liberty to exercise the arbitrary power of ejecting the contractor. His Honour then referred to the case of Heap *v.* the Archbishop of Canterbury, in which, if he recollected aright, a party contracted with the commissioners for building churches that a contract should be performed to the satisfation of certain individuals. Upon a question of forfeiture for breach of contract, it was urged that the stipulation was arbitrary and unjust; but the answer was, it was quite impossible for the persons on whose behalf the work was done, themselves to form a fair opinion upon it, and they were perfectly justified in stipulating that it should be performed to the satisfaction of some given individual on whom he had reliance, and, if he was not satisfied, they meant, as the contractor was aware, that there should be no appeal. He could not for the life of him think but that the company meant to reserve, and did reserve, to themselves an arbitrary right to dismiss the plaintiff; and although it was stated in the bill that the company had dismissed him with a view to get hold of his property, and so on, that may be true; yet, if they have dismissed him, they have only exercised the right which they possessed, and the exercise of that right was followed with consequences which they did not contemplate, and which were mere accretions in exercise of the right. Just consider the power of arbitrarily dismissing persons in their employment, which parties possess, in many instances, under the law of England. Put the case of common day labourers or servants. You may go home, a complaint may be made, and you dismiss your servant, and refuse to give him a character, yet he has no redress. If you give a false character, that is a different matter. But supposing the power of dismissal in this case were not arbitrary, he could not see how the court could interfere. If the forfeiture was legal, there was no redress at law. A party applying for equity must do equity. And how was a court of equity to relieve against the forfeiture without providing for the execution of the contract? And if the court will not execute a building contract, *a fortiori*, it will not execute such a contract as this. Thus the court was disabled from giving any equity to the plaintiff, because it was disabled from giving that reciprocal equity to the defendant of effectually providing at once for the completion of the railroad without interruption, to which he was entitled. And if the court cannot relieve the plaintiff because it cannot relieve the defendant, there is no portion of the bill on which it can be sustained. The case was nothing more than that the company had illegally, and without warrant, seized the plaintiff's spades, wheelbarrows, &c., and therefore the bill was filed. There was no case for an account. The payments were all on one side for work, and labour on the other. If there was a question of trespass, or if there was a question upon a *quantum meruit*, a court of law was the place where that should be decided; but so long as the work was in progress this court could not interfere. He should therefore allow the demurrer.

This decision, of course, disposed of the motion for the injunction.

Against this decision the plaintiff appealed to the Court of Chancery, the appeal was argued before the Lord Chancellor on the 23rd of August last, and following day. On Tuesday, December 4th last, the Lord Chancellor delivered the following judgment, reversing the decision of the Vice Chancellor:—

This was a demurrer which came before him during the long vacation. He had been induced to hear it, although the sittings were terminated, because it was represented as necessary that the demurrer should be disposed of in order to give the party an opportunity of moving for an injunction; but he was so satisfied from the discussion which took place on the case made by the bill that it was not one in which he should interfere, that he had delayed pronouncing his opinion till now. The demurrer was a general demurrer by the Great Western Railway Company, on account of multifariousness; but he saw no reason for entertaining it on that ground, the company being immediately interested in the whole matter introduced in the bill. It remained to be considered whether the general demurrer for want of equity could prevail. It could not of course prevail, if there was any part of the relief prayed to which the plaintiff was entitled. The bill was certainly singular in its form, because it prayed that the defendants might elect whether they would restore the plaintiff to the situation in which he was in possession of the work, so as to enable him to complete the works he had contracted to perform, or if not, that they should consider the contract at an end; but in either alternative the prayer was, that the accounts which subsisted between the plaintiff and defendants might be taken. In was not necessary to go into the very detailed circumstances laid before him at the hearing, because if any part was capable of giving an equity, of course the demurrer could not prevail. But for the purpose of explaining the view he took of the case on the bill, it was sufficient to state, that the plaintiff alleged he had entered into contracts to do certain works on the railway; that it was part of the provisions of those contracts that the surveyor and engineer of the company should every fortnight ascertain the quantity, or rather the value of the work done according to certain stipulated rates of charge; that the contractor, the plaintiff, should be paid four-fifths, 80l., out of every 100l., for the amount of work so ascertained to be done, the 20l. per cent. unpaid being to remain in the hands of the company until it had accumulated to a certain sum, 4,000l., and on attaining that amount, the engineer having satisfied himself that the work was well done, the contractor was to be paid the whole that was due. In these contracts there were certain conditions imposing great penalties and giving great powers to the railway company. Among others there was this condition—if the engineer should not be satisfied with the mode in which the works were conducted and the progress made, the company were to give notice to the contractor to prosecute the works, and if he did not within seven days prosecute the works, they should be at liberty to enter upon the works in progress. Upon that taking place, not only all the plant, machinery, utensils, &c., employed by the contractor was to become forfeited to the company, but the plaintiff was also to forfeit all that remained unpaid on the work previously done—*i. e.*, that the money actually paid should be considered in full satisfaction of the work up to that time. If the engineer had done that which the contracts required—if he had provided for the payment, according to the contracts, of 80l. per cent. on all the work done every fortnight, the forfeiture would have operated on the 20l. per cent. remaining unpaid; but the case made by the bill was, that this had not been done, and that in fact the engineer, favouring the company and acting oppressively towards the contractor, did not estimate the work done so as to give the contractor 80l. per cent. According to the statement in the bill, a very much larger sum was due to the contractor than 20l. per cent. on the previous estimates, yet the penalty was sought to be enforced on all that was due, not only to exclude the contractor from the 20l. per cent. not paid, but also from a very large proportion of the 80l. per cent. which he ought to have received. How was this, then, to be ascertained? Only by an investigation of the work done, and the mode in which the engineer had estimated it. But that was not the whole case stated in the bill. Independently of the works carried on under these several contracts, which were in writing, there were other contracts not in writing; there was also what was called the extension contract for carrying on the line, which was not in writing, but to be carried on at certain stipulated prices. Under that contract, the bill alleged payments had been made, but very large sums still remained unpaid. The bill stated that upwards of 30,000l. remained due on works actually completed by the contractor; so that if the company were right in doing what they had done, and enforcing the contracts for forfeiture, they were in possession of a large sum of money, which, even in that case, must be coming to the plaintiff, while the amount could only be ascertained by the quantity of work done, and the mode in which payment had been calculated—an investigation obviously which could only take place under the superintendence of a court of equity, for it was utterly impossible such an account could be taken in any court of law. The case, however. went still further than that. The bill stated, that the plaintiff being pressed for money to carry on the works, applied to the company for an advance on loan; they consented, and three several advances were made, secured on the property of the contractor—namely, on the plant, utensils, and tools employed in carrying on the works, and by a mortgage on what remained due to him, the 20*l.* per cent. for work previously done, but that the bill alleged applied only to the plant, implements, and tools for the works under the written contracts: it did not apply to the plant, utensils, and tools employed on the contract not in writing. The company, however, had taken possession of the whole; they claimed all under the penalty as forfeited. Now, the bill contained a statement which, if true, showed that the company had no title under that clause of forfeiture. The forfeiture could only be enforced if the contractor disregarded the monition after seven days; and the bill alleged that within the seven days, taking up the very words of the contract, the plaintiff had put himself in that situation, which, if true, would have prevented a forfeiture. The company therefore had no title under that clause of forfeiture; but if they had no title under that clause of forfeiture, they were in possession of large property, stated in the bill to amount to 70,000*l.*, on which they undoubtedly had a lien for the repayment of the sums advanced to the contractor. The bill also stated that the engineer of the company declared that in making the certificates he should consider what was the state of the account upon all the contracts. The result, therefore, would be, according to the allegations in the bill, that the defendants had illegally and without authority possessed themselves of property which they contracted to leave in the hands of the plaintiff, and an unsettled account remained between them. It was impossible to say, if such a case were made out, that the Court would not administer some relief; it was impossible to say the plaintiff had no equity, and the demurrer could not be supported.

The Vice-Chancellor's decision allowing the demurrer was accordingly overruled.

PRIVY COUNCIL, Wednesday, Dec. 12.

The petition of James Russell, Esq., of Handsworth, came on for hearing before the Privy Council this day. The lords present were Lord Brougham, Mr. Justice Parke, Mr. Justice Bosanquet, Sir Stephen Lushington, and the Hon. Mr. Erskine.

The petitioner prayed for the renewal of a patent "for certain improvements in manufacturing tubes for gas and other purposes," assigned to him by Cornelius Whitehouse, a workman employed by him for the purpose of carrying into effect the manufacture of tubes by machinery.

Mr. Cresswell (in the absence of Sir William Follett) detailed the history of gas-tubing from the period of the application of old gun-barrels for that purpose. The present invention had arisen in consequence of the petitioner having been prevented by the combination of his workmen from meeting the demands of the Gas Companies for tubes, the supply afforded by manipulation being limited, and too dependent upon the caprice of his workmen to allow him to enter into contracts. The great demand for the patent tubing, and its great superiority over the hammered tube, had led to numerous infringements, which, coupled with the enormous extent of litigation consequent on such piracies, had deprived the petitioner of the fair and adequate remuneration he ought to have obtained for so valuable an invention, without which gas-lighting could not have been carried on to its present extent, and which had led to several inventions of great utility.

Angier March Perkins, Esq., Civil Engineer, proved that he was the inventor of an improved method of heating buildings, which had been adopted in the British Museum, Milbank Penitentiary, and in many churches, houses, and other buildings, both public and private, to a great extent, and that his patent was entirely dependent upon the patent tubing of Mr. Russell, without which he could not have carried out his invention.

Francis Bramah, Esq., Civil Engineer, proved that he had inspected Mr. Russell's works, and was delighted with the beauty of the invention; that he had for some years used the patent tubing, and had submitted it to a pressure of 3 tons upon the square inch. Mr. Bramah also spoke to the great reduction in price effected by the patent, and its utility for hollow axles, spindles for machinery, and a variety of mechanical purposes, independent of its value for transmitting heat, gas, or fluids.

The Lords of the Council having intimated their opinion that the value of the patent was in some degree proved by the numerous decisions of the Courts of Law in its favour, the accounts were put in and verified.

Mr. Fletcher, of Dudley, as solicitor to the petitioner, produced the original patents and other documents, and proved that he had complied with the regulations pro- gated by the Privy Council.

The Att ey General then addressed their Lordships on behalf of the Crown, and st..ed that he was fully acquainted with Mr. Russell's patent, having been employed in opposition to it in different Courts of Law. He could, however, fully attest the value and utility of the invention; and if their lordships should be of opinion that sufficient remuneration had not been afforded, he should, under the peculiar circumstances of the case, rejoice if their lordships would grant an extension, in order that adequate reward might be given to an invention of great public benefit.

Lord Brougham: Their lordships having taken the whole of this matter into account, retain the opinion which they have had impressed upon their minds from the very beginning—that this is an invention of extraordinary merit, doing the greatest honour to the inventor, conferring great benefit on the community; founding in this eminent merit not merely the application of a known principle embodying it in new machinery, and applying it to practical purposes, but involving the discovery of a new, curious, and most important principle, and, at the same time, applying that principle to a most important purpose. Their lordships have on the same side of the question taken into account (which it is material to mention) Mr. Russell's merit in patronising the ingenious and deserving author of this invention, in expending money till he was enabled to complete this invention, and in liberally supplying the funds which were requisite for the purpose of carrying this invention into execution. On the other hand, their lordships have taken into mature consideration (which they always do in such cases) the profit made by the patentee, Mr. Russell, standing in the place of the inventor. They find that it is not a case, as in claims of other inventions of great ingenuity and certainly of great public benefit, of actual loss in some, and of very scanty if any profit at all realised in others, but that a considerable profit has been realised, and upon the whole no loss. It is to be observed that the profit is not, perhaps, very much greater, if at all greater than the ordinary profits on stock to that amount employed without the privileges and extra profits of a monopoly. It is proper to consider that one great item of deduction from those profits also involves great pain and anxiety and suffering to the party, namely, the litigation to which he has been subjected, and which is generally found to be in proportion to the merit and the usefulness of a patent, namely, the temptation to infringe it, and to set at nought the right of the patentee, both in the Court of Chancery, when he applies for protection by injunction, and afterwards in a Court of Law, when he comes to claim compensation for damages; the temptation being, as I have stated, in proportion to the benefit and the demand for the invention. That is an item which has, to a considerable degree, attracted the attention of their lordships in this profit and loss account which has been laid before them in the course of these transactions. Taking the whole of the matter into consideration—the merits of the patentee, the merits of Mr. Russell, and the loss that has been sustained in the litigation—and setting against those, on the other hand, the profits which have been made, their lordships were of opinion that the term ought to be extended, and upon due execution being given to the undertaking, which has been just given by Mr. Fletcher on behalf of the inventor, that the term ought to be extended for the period of six years.

STEAM NAVIGATION.

An iron steam vessel, of 60 tons burden, 71 feet in length, and 10 feet of beam, with wheels at her stern, constructed on the sculling principle, called the Robert J. Stockton, came round from Liverpool to London upon an experimental trip, during the late tremendous weather, and arrived in the river in safety on Monday evening, Dec. 3. The superiority of the wheel introduced into this vessel, in comparison with what is called the Archimedean screw, and other contrivances, was satisfactorily shown, and no doubt whatever is entertained of its extensive adoption. The Robert J. Stockton will in a few days proceed on a voyage across the Atlantic.—*Evening paper.*

Steamer.—On Thursday morning some curiosity was excited at Blackwall, and below, towards Gravesend, by the novel spectacle of a large heavy-laden ship proceeding down the river propelled by a steam apparatus. Her appearance was that of an ordinary vessel, with the exception of a few bars of iron on her sides, crossed in different directions, to which the propellers appeared to be attached. No paddle-boxes were visible, nor was the water thrown up, as in the case of the paddle-wheels—the action seemed to be smooth and equable. This is the first attempt, as far as we know, to adapt the use of steam power to propel a vessel of the ordinary construction; and it certainly does, on reflection, seem extraordinary that some plan for effecting this object should not have been, before now, brought into beneficial use, the enormous expense attending the constant consumption of fuel in steam vessels being the great obstacle to the application of steam power to distant voyages. The ship above alluded to is the Maria, going to India; her machinery, including the boilers, occupies comparatively little space.—*Daily paper.*

Newfoundland Steam Navigation.—The House of Assembly of Newfoundland have voted 600*l.* for the promotion of steam communication between Newfoundland and Great Britain and Ireland.

Bordeaux and New York Steam Navigation.—A public meeting, attended by eighty-nine of the most respectable merchants, was held at Bordeaux on the 29th of Nov., and appointed a committee to take preparatory measures.—*Commerce.*

North America.—The important topic of steam-navigation to the British North American colonies is engaging much attention in Halifax and St. John's. Mr. Howe, who had been advocating in England the expediency of a change in the present system, has returned to Halifax.—*Morning Advertiser.*

West India Islands.—We have seen, within the last few days, a circular containing a prospectus of a plan for opening and maintaining a regular communication by steam betwixt Liverpool and the different West India Islands.—*Liverpool Albion.*

Brazilian Steam Navigation.—The Bahia people were looking forward with impatience for the arrival of some of the steamers which the Bahia Bay Steam Navigation Company proposed to put into operation in that quarter, and there seemed to be every disposition on the part of the residents to give all the encouragement in their power to the undertaking.—*Morning Post.*

French Experimental Steam-Boat.—The steamer Veloce has received orders to hold herself in readiness to sail for Havannah and Mexico, to try the new system of masts adopted by her commander, M. Bechameil. The question whether steam and wind can be combined will thus be speedily solved.—*Armoricain.*

Steam Cutter.—The United States discovery ship in the South Seas, the Macedonian, has an eight-horse steam engine to put into the cutter of the frigate, to ply up the various rivers in New Zealand.

Adriatic Steam Navigation.—The Austrian Lloyd's Company have established steam vessels between Ancona and Trieste.

The Royal William started on the 15th ultimo from Liverpool for America. She was provided with fuel sufficient for 27 days, of which 30 tons 9 cwt. were of Mr. Williams' patent peat stone fuel.

PROGRESS OF RAILWAYS.

Railway to Lewes and Hastings.—The plan comprehends a line of railway, commencing from the line of the London and Brighton Railway, at St. John's Common, and running in nearly a straight line to Lewes, where it crosses the river a short distance below the bridge; it is then carried on through the levels of Laughton, across the Cuckmere river near Selmeston, and from thence through the Eastbourne and Pevensey levels, passing to the north of Eastbourne, and in front of the Castle at Pevensey, and thence in nearly a straight line to St. Leonard's and Hastings. The line selected passes through so level a country, that the works required for its construction are scarcely of greater magnitude than those of ordinary turnpike roads, which is a circumstance of the most material importance, as diminishing the cost of the line far below the usual average cost of other railways. The gradients are also peculiarly favourable. In connexion with this line of railway, it is proposed to construct a ship canal from Newhaven Harbour to Lewes, with a wet-dock and basin at Lewes, a little below Lewes bridge; the canal will contain twenty feet depth of water, and by reason of avoiding the intricate windings of the river, will reduce the distance from Newhaven bridge to Lewes to five miles and a half. By this canal, therefore, Lewes will become, as of old, a port, and the whole of the trade and commerce of the district be brought to the merchant's own door.—*Sussex Express.*

Brandling Junction Railway.—Every exertion is being made to open this line of railway for public conveyance as early as January next. Four splendid locomotive engines, from the factory of Messrs. Longridge and Co., at the Bedlington Iron Works, have this week been forwarded through this town for the Brandling Company; and, from what we can learn, those engines called the Brandling, Newcastle (now being tried on the Newcastle and Carlisle line), Bedlington, and Gateshead, are of a very superior construction, and reflect much credit upon the manufacturers of them.—*Newcastle Journal.*

A Contrast.—Great Western Railway.—The works on the Great Western Railway, near Reading, continue to be at a total stand-still. Some of the labourers are begging about the streets of that town, and others have left, to obtain work elsewhere.—*Reading Mercury.*—The works on the Great Western Railway, between Reading and Didcot, are progressing with a rapidity and punctuality exceeding that on any other portion of the line. There is a report that a temporary station will be erected between this town (Reading) and Twyford in April, but we do not believe it will be required so soon.—*Berkshire Chronicle.*

We understand that the eastern arch of the Maidenhead bridge has been taken down, for the purpose of rebuilding it: this we were afraid would be the case when we surveyed the bridge in June last.

London and Southampton Railway.—Part of an embankment on this line, near Weybridge, gave way, and blocked up the road so as to oblige the passengers by the five o'clock train to leave the carriages.

London and Brighton Railway.—The works on the London and Brighton Railway are proceeding in the most satisfactory manner. There are 1,600 men now employed on the line. Messrs. Thornton are making rapid progress in the Long embankment north of Clayton-hill: and the tunnel shafts at Merstham, Clayton, and Balcombe, are nearly completed. In order to expedite the execution of the works in the Shoreham branch, it is understood that a double set of men are engaged for the cutting on Mr. Fuller's farm at Aldrington, the work being by these means carried on night and day without intermission.—*Brighton Gazette.*

London and Greenwich Railway.—On Tuesday, the 4th of December, the remaining portion of the London and Greenwich Railway, extending from Deptford to the Prince of Orange public-house, in Greenwich, was privately opened, under the superintendence of the directors, who were accompanied by Colonel Landman, the engineer. The new part of the line is laid upon longitudinal wood bearers, supported upon transverse wood sleepers upon a bed of ballast. The top of the arches have been coated with Claridge's asphalte. On the 24th December it was opened to the public.

Great North of England Railway.—The workmen have now commenced laying the foundation of the fifth and last bridge of the Great North of England Railway, near Northallerton, a little to the south of the town, which will cross over the high road leading to Boroughbridge, near to the 220th milestone from London.—*Newcastle Journal.*

Tamworth and Rugby Railway.—So confident are the parties engaged in this undertaking of obtaining their act for carrying the Manchester Railway through Tamworth to Rugby, that a legal gentleman in the neighbourhood of Nuneaton has received authority to contract for the purchase of any land which may be required in that district.—*Birmingham Advertiser.*

Manchester and Leeds Railway.—The portion of this extensive undertaking which lies betwixt this town and Rochdale is in a very satisfactory state of forwardness, and will, in all probability, be opened in May or June next. Of the part betwixt Mills Hill and Rochdale, which was the most heavy and difficult, about three parts in the hundred only remained unfinished in the middle of November. The cuttings and embankments, the latter including the important one of Mills Hill and Castleton Clough, were nearly perfected, and permanent rails will be laid in good time on the whole of those works. The bridges (from a difficulty in obtaining stone) were the only works not in a corresponding state of forwardness. The tunnelling at the summit is proceeding as fast as human skill and activity can promote it, and at Gauxholme a large muster of workmen are daily employed in sinking foundations and cutting stone for the erection of warehouses and other requisite buildings.—*Wakefield Journal.* The line of railway from Manchester to Littleborough is advancing so rapidly towards completion, that, if the severity of the weather do not materially protract operations, it will certainly be ready for opening, between these two places, in the spring of next year. About half of the permanent rails have, we understand, been already laid.—*Halifax Express.*

Manchester and Birmingham Railway.—A deputation of the directors, accompanied by G. W. Buck, Esq., the engineer, met the committee appointed by the town council of Macclesfield, in order to communicate to them the plan for a diversion of the proposed branch to Macclesfield. Mr. Buck's report was read; it stated that the Macclesfield branch enters the main line in a cutting, on a curve, and at the foot of an inclined plane which is upwards of a mile in length. Under such circumstances, approaching trains would be invisible to each other, and, therefore, to prevent accidents from collision, it would be absolutely necessary that the trains coming from Macclesfield should stop before entering upon the main line; but stopping here would be impracticable, on account of the momentum acquired in descending the inclined plane. Again, although no trains might be approaching on the main line, still the Macclesfield trains should enter the main line at a slow speed, which would be impracticable for the same reason. It is obvious that these defects are such as would constantly give rise to serious accidents, and, therefore, ought, if possible, to be obviated; with that view, Mr. Buck recommends that the Macclesfield line shall branch off near the seventh mile, on the Parliamentary plan, at Cheadle Hulme, and thence proceed in a direction nearly south, passing by the Siddall houses, then gradually bearing eastward to Hollingworth smithy, where it should pass under the road to Adlington Hall, and fall into the Parliamentary line a short distance beyond, from which place to Macclesfield the Parliamentary line will be retained. By diverting the turnpike road near the Mill-house, no crossing of it will be required in the whole distance, except at Beech bridge. The length of this deviation will be about 5¼ miles, of which the first 26 chains adjoining the main line may be level, and the remaining distance will have an ascent of 20 feet in a mile, or 1-264. From Hollingworth smithy to Macclesfield, the railway may be constructed of one gradient of 1-232, or about 23 feet in a mile. The advantages which will accrue from adopting the proposed line are the following:—The length to construct will be about one mile less. The junction takes place where the main line is straight, upon a level, and upon a small embankment. The maximum gradient will be 1-232, or about 23 feet per mile, whereas on the Parliamentary plan, it is 1-150, or 35 feet per mile. The proposed line will be cheaper to execute and cheaper to work.

Manchester and Birmingham Railway.—The extensive viaduct across the Mersey and valley at Stockport, has been left to Messrs. Tomkinson and Messrs. Holme, of Liverpool, at a little below £70,000. It will have twenty-two arches of between sixty and seventy feet span, the centre arch crossing the river at a height of 100 feet. The lowest estimate was about £62,000, and the highest was about £100,000.—*Macclesfield Courier.*

Sheffield and Rotherham Railway.—The station and its vicinity still continue the great scene of attraction. On Sunday the number of passengers conveyed amounted to 2,500. The number of passengers who have travelled on the railway since it was opened for business, have averaged 1,350 daily. A gentleman has made a wager that 800,000 persons will be conveyed in the railway carriages during the first twelve months.—*Sheffield Iris.*

Birmingham and Gloucester Railway.—The Gloucester portion of the line is rapidly approaching to completion. The earthwork is remarkably light, as is also the masonry, of which the whole is being executed at prices hitherto unknown to railway proprietors. Workmen are engaged all along the line, which is let in small contracts. At Tewkesbury the depot is commenced, and the Lansdown depot will be immediately proceeded with—the drawings being already in the builder's hand. A plain but elegant skew bridge, under the Arle road, is now waiting for the iron work; and we observe the workmen very busy on the large bridge which is to carry the old Gloucester road over the railway.—*Cheltenham Looker-On.*

Chester and Birkenhead Railway.—We understand that Messrs. Clements and Henry, the contractors for the Chester end of the Birkenhead and Chester Railway, are progressing satisfactorily in the heaviest portion of their work—viz., the filling up of the valley, and the erection of the bridge over the Dee and Mersey Canal at Mollington. They are preparing an inclined road, and fitting up a stationary engine at great expense, in order to expedite the conveyance of the earth into the valley. Great progress has been made at the other end of their contracts, near Sutton; a great quantity of earth has been removed, and through the deepest portion of the cutting great preparations of material are now being made, in order to prosecute vigorously the whole line next year; combining the lighter portions of the work between Mollington and Chester, as also on the other end, between Sutton and Plimyard Brook, in the township of Eastham, which terminates their portion of the line.—*Chester Gazette.*

Glasgow and Ayr Railway.—We are enabled to inform the public that this great national undertaking is carried on most satisfactorily, and that the whole expenses yet incurred have not exceeded the parliamentary estimates—a circumstance as unprecedented as creditable to Mr. Miller, the engineer. The same may be said of the first part of the line as far as Paisley, which is executed by Mr. Locke, for the Ayrshire and Greenock Companies jointly. The whole line, we are assured, will be completed by the time the Glasgow end is ready, which will be in the spring of 1840.—The Earl of Eglinton has, we understand, determined on completing the harbour and docks at Ardrossan, and making the necessary arrangements for goods and passengers; whilst the inhabitants of Ayr are also bestirring themselves to render their river harbour as good as it is capable of becoming, and a company is already formed to establish a steam navigation from Troon to Belfast.—*Glasgow Courier.*

Glasgow and Greenock Railway.—The directors, at their last meeting, let the two remaining contracts on this line, Mr. Brassey having gained the Walkinshaw, and Mr. M'Kenzie the Finlayson. Judging from the rapid progress already made by these gentlemen at Arkleston and Bishopton, there is no doubt but the opening of the railway to the public in the early part of the summer of 1840 is secured.—We understand that at the Bishopton ridge nearly 100,000 cubic yards have been excavated, that one steam engine is already at work, for pumping the water and hauling the rock from the tunnels, and that another engine is preparing here at Messrs. Johnston's works.—At Arkleston the same rapid progress has been made, the tunnel shaft is completed, and the tunnel commenced. About 90,000 cubic yards have been excavated, and ballast of a very superior quality has been found in great abundance.—In this town the masonry for carrying the railway over the streets is proceeding rapidly for the season; four arches are turned, several others in hand, and a length of wall is built.—The works are equally stirring at Port-Glasgow, where, for nearly half the length of the town, the masonry is in progress.—In Paisley, the large bridge over the river Cart is built above flood water, which is very creditable to the contractor, Mr. Lyon, who only commenced work late in the season. The bridges over Gilmour-street and Greenlaw-street, together with the retaining walls, are also considerably advanced.—Two cargoes of rails have arrived from Bristol, and several miles of the road will be laid early in the spring.—*Greenock Advertiser.*

Edinburgh, Leith, and Newhaven Railway.—An elegant and substantial bridge, of thirty feet span, under the Queensferry road, about one mile from the city of Edinburgh, has been finished, under the superintendance and design of Mr. James Adam, jun., the assistant engineer, for 1,400*l.* The lowest offer by contract was 1,000*l.* The contract from this bridge to the Water of Leith is now nearly completed. It consists of embankments and excavations of thirty-four feet in height and depth, and has an interesting appearance from the city. The contract at Trinity is also far advanced. The principal depot is situated at this terminus; and from this it is intended to carry the branches to the pier at Granton, and the harbour at Leith. It is also expected that the tunnel will be commenced immediately, at the principal depot at Canal-street. The Edinburgh and Glasgow, as well as the great Newcastle and London line, will terminate at the same spot, which is in the very centre of the city.—*Railway Times.*

West Cumberland Railway.—Another source of distrust towards the coast line scheme is that the parties do not look for obtaining the general support and concurrence of the residents in the districts through which the line is to pass. This may account for the cavalierness of the committee, but it also suggests that some jobbing interest is at the bottom.—*Kendal Mercury.*

Railway to Glasgow.—The people of Glasgow have already begun to evince their anxiety to unite with Carlisle, to communicate with the south, either by Mr. Hyde Clarke's Morecombe Bay Line, or that over Shap.—*Dumfries Courier.*

Scotch Railway.—The Dumfries people are anxious to form a junction with Carlisle, and to give every assistance for this object. It would be worse than superfluous in us to add one word of argument in support of the eligibility of Mr. Hyde Clarke's West Cumberland railway communication with Scotland.—*Dumfries Times.*

Preston and Lancaster Railway.—The operations on this line of railway are proceeding with great activity, and, so far as the work has proceeded, everything has been highly favourable. A great number of men are at work, and the respective contractors are sparing no pains to advance the works with all possible rapidity.—*Manchester Guardian.*

Eastern Counties Railway.—The following is a statement of the progress of the works on this line between London and Romford:—*Works completed in Brickwork, Masonry, and Iron*—A bridge over the Regent's Canal, of iron, 56 feet span; bridge over the river Lea, 70 feet span; Stratford viaduct, of five arches, 36 feet span each; Mill Pond bridge, 46 feet span; Stent's bridge, of four arches; Abbey bridge, 32 feet span; Aldersbrook bridge, 40 feet span; Roding bridge, 40 feet span; Romford river bridge, 30 feet span, in 34 feet embankment; Essex turnpike-road bridge, carried over railway on cast iron girders for a distance of 154 feet; besides 11 bridges over public roads, and six occupation bridges; six other road bridges are in progress, and also the viaduct between Cambridge row and Devonshire-street.—*Earthwork*—Embankment over Regent's Canal to Hatfield's archway, nearly ready for ballasting and permanent way; from Grove-road bridge to Tredegar-square, the embankment up to the ballast line; Coborn-road to Fairfield-place, embankment partially formed; from the west culvert to Forest-gate, the cutting and embankment complete, and the permanent way laid for nearly two miles; from East Ham up to and beyond Ilford, the cutting and embankment crossing the Ilford valley complete, and the permanent way laid for more than a mile.

The portions of cutting and embankment not yet begun amount to not quite a mile and three quarters. About a mile and a quarter consists of a cutting only eight feet in depth, in very favourable soil; a quarter of a mile is embankment, not averaging six feet in height, and the remaining quarter of a mile is that portion of the embankment over the Stratford marshes, where the ground for a depth of eight feet is inclined to " spew up." Considerable difficulty and delay might have arisen by the consequent subsidence of the embankment, but this has been completely obviated by carrying a frame-work of timber, supported upon piles, in advance of the operations. A certain proof of this, is the fact, that between the 11th of September and the 23rd of October, the embankment was carried from the east side of the Carpenters' Company's occupation archway over Stent's Mill bridge, a distance containing 44,680 cubic yards, although the lead was one mile and a half.

In order to insure an early opening of the line up to Romford, four locomotive engines are working night and day in the formation of the embankments.—*Extracted from the Railway Times.*

A Railway Warner.—There is an ingenious contrivance by which accidents may be effectually prevented. It consists of a bar of iron fixed in front of the engine, at a small distance above the rails, crossing the whole breadth of the road, which pushes any obstructing body before it, and, when so obstructed, rings a bell, which gives notice to the engineer. The benevolent inventor allows the use of his contrivance gratis.—*Morning Advertiser.*

Railway Missionaries.—The Bishop of Bath and Wells has appointed the Rev. F. Campbell, M.A., as a missionary among the navigators employed on the Bristol and Exeter Railway. The Railway Directors, and the Church Pastoral Aid Society, have liberally contributed, and it is hoped that the same well-judged efforts will be made elsewhere to reclaim them from their present heathen state.—*Bath paper.*

FOREIGN RAILWAYS.

Railway from Brunswick to Harzburg.—The first section from Brunswick to Wolfenbuttel was opened on the 30th of November. The duke himself was present on the occasion, and the train, consisting of five carriages, set out at twelve o'clock, and reached Wolfenbuttel (seven English miles) in twenty minutes. The duke, the ministers of state, and other distinguished persons, were highly pleased with the result of this trial, which was loudly cheered by the crowd that had assembled to witness the novel sight. On the return, it was resolved to divide the train between two machines, in order to try their power and the goodness of the road. Their progress was accelerated as much as possible, and the seven miles were passed in ten minutes. The road was opened to the public on the 1st instant, and in the first seven days there were 6,527 passengers, and the number would have been much greater, did not the shortness of the days prevent the trains from going more than four times in the day, backwards and forwards.—*Hanover Gazette*, Dec. 11.

Nuremberg and Furth Railway.—The number of passengers on this line in three years has been 1,357,286, and the receipts 173,443 florins. During this period no loss of life has been incurred.—*Globe.*

Havre Railway.—Two important measures were adopted at the recent meeting of the Council of Administration of the Havre Railway Company, which decided that a new survey shall be made of the whole line from Paris to the sea by the engineers of the company, and has also named from amongst its members a committee charged to discuss with the Government the modifications which it may be necessary to introduce into the contract, in consequence of the estimates and plans to which the investigations above alluded to may lead. Till the expenses of the railway shall be laid down with accuracy and precision, the Council of Administration, it adds, has suspended the works which were commenced according to the estimates of the Government engineers, but which might have compromised the capital of the shareholders in an undertaking impossible to be terminated with the funds at the disposal of the company.—*Commerce.*

Havre Railway.—The committee have determined to have the whole line re-surveyed by their *own* engineers, *not being able to place any dependence on the government engineers.* M. Lebobe has been appointed temporary managing director in the place of Count Jaubert.—*Commerce.*

The German Diet, before it broke up, took a resolution which has caused great joy at Mayence. It consented that the iron railroad of the Taunus should have its terminus in the federal fortress of that city, and even that one of the bastions should be pierced, if necessary, for that purpose. It seems that the Bavarian ambassador declared that he had orders to oppose whatever might, in the smallest degree, affect the security of that important fortress. The Austrian and Prussian engineers declared that there was not the smallest danger in complying with the wishes of the citizens of Mayence; and an eminent Danish engineer clearly demonstrated it.—*Morning Chronicle.*

Austria.—The statutes of the company for the Milan and Venice Railroad have been approved of by the Austrian government, and the works are to be commenced next spring. The journey will be accomplished in eight hours, and the fares are to be exceedingly moderate.

America.—The late accounts from the United States present some interesting details of the progress of the improvements in the free states of the federal union. The state of Pennsylvania has completed the survery of the route of the railroad to connect Pittsburgh with Philadelphia, and the state was about to make an immediate appropriation for making on its own account a railroad to connect it with the Harridburgh and Lancaster road, by which the Ohio and other great rivers will be reaches in 24 hours. The same state has also made a railway to Lancaster, and will continue it from Harrisburg.

ENGINEERING WORKS.

Fortification of Sheerness.—A survey of the Isles of Sheppy and Grain has been going on for some months past by order of Government, with a view of immediately fortifying her Majesty's Dockyard, which is at present without almost the slightest power of resisting an invading foe. Several plans have been laid before the Lords of the Admiralty, but the one that is most likely to be brought before the house next session proposes a line of fortification across the range of hills extending from Minster church to the Swale. A range of batteries here, it is said, will cover the whole island, and would at any time prevent an enemy from landing at the south-eastern extremity. The Dockyard and Miletown are to be covered by strong batteries, and martello towers will be also erected along the shores at given distances. The Isle of Grain is to be fortified with strong batteries, extending in the shape of a half-moon. These will not only cover the entrance of the Thames, but also the Medway. The estimated expense is nearly a million and a half of money.—*Greenwich Advertiser.*

London Docks.—A great improvement has been lately made in these docks, by the erection of a magnificent jetty, supported on massive piles, extending from the south-west quay, eight hundred feet across the large basin, affording a quay frontage on both sides for the loading of outward-bound ships of 1,600 feet. The jetty is 62 feet in width, and three lofty sheds, each 208 feet long by 48 feet wide, for the reception of goods and merchandise for exportation, are in the course of erection; one of these store-houses is already completed. There will be a space of seven feet clear on each side of the warehouses. The erection of the jetty is said to have cost the London Dock Company not less than 60,000*l.*, and it will afford great accommodation to the shipping, and particularly to the Sydney and Hobart Town ships. There are now eight large vessels bound to those places lying alongside the new jetty. They will all carry out a great number of emigrants. There is sufficient depth of water for the largest ships in the jetty, and at spring tides there is twenty-three feet of water. The whole work reflects great credit on the skill and enterprise of the respectable commercial body by whom it was designed. A capital of one million sterling has been expended during the last twelve years in enlarging and improving the London Docks, including the excavation of the eastern bason and entrance, and we understand further improvements are in contemplation. The dock, with the various rows of lofty warehouses and vaults, is the first establishment of the kind in the world.

The Eddystone.—We feel great pleasure in stating that, on examination by the competent authorities sent here from the Trinity Board, it is ascertained that the Eddystone Lighthouse has not sustained the slightest injury during the late severe storm. The report forwarded from this port to London, that it was feared that the lighthouse had been severely damaged, created, as might be imagined, great sensation; and an eminent engineer (Mr. Burgess), and a member of the Trinity Board, were immediately dispatched to ascertain the extent of the injuries, and preparations were made to place a floating light near the rock, if it should be found necessary. On the arrival of the deputation here they proceeded to the rock and commenced their survey, making the most careful examination throughout the structure. They repeated their visit a few days after, accompanied, we understand, by two efficient public officers of the port, and we are enabled to state, from what we consider undoubted authority, that it has been found that the noble structure has not received the slightest damage, unless the washing off the paint from a portion of the upper part of the building, which exhibits a crevice in the paintwork about a yard in length, and damaging two of the panes of glass in the lantern to the extent of a quarter of an inch, be called injuries. The result of the survey will, no doubt, be made public, in order to restore confidence as to the stability of the edifice after the alarming reports which have been made. It may be fairly presumed that the extreme violence of the storm, and its continuation for so many days, created fears in the minds of the men in the lighthouse for their safety, and this, no doubt, gave rise to the rumour that the building had been shaken by the storm.—*Plymouth Herald.*

Plymouth Breakwater.—The utility of this great national work has been fully demonstrated in the late storms. All the vessels in the Sound rode out the gale, though at high water there was a heavy sea rolling over the Breakwater. It is feared, indeed, that it will be much injured; all the cranes on the west end have been washed down by the violence of the sea.

Port Carlisle.—The wet and dry docks and pier are in active progress under the superintendence of Mr. Boyd. The contract for the pier has been taken by Mr. Nelson.

Fortifying the Coast.—Surveys are being made on the east coast of this county and the river Humber for the most eligible sites on which may be erected batteries, in the event of hostilities with Russia. Whether a war now take place or not it is intended to secure the ground in the event of any future occasion. A site at High Paull and the opposite coast will be again occupied as military establishments for the defence of the Humber.—*Hull paper.*

Ardglass Pier.—The lighthouse and part of the pier at Ardglass, in the Bay of Dundrum, which had been nearly completed at an expense of 26,000*l.*, were destroyed by the violence of the late storms.—*Morning Post.*

Semaphore on Shooter's-hill.—The engineers have been surveying the ground between Shooter's-hill and Woolwich, for the purpose of erecting a semaphore, and perhaps a fort, upon that spot. Should a battery be erected there, it would be found that one or two traversing guns will command the river below the Royal Arsenal.—*Rochester Gazette.*

Dangerous State of the South Coast.—During the late severe gales, upwards of 100 lives were lost on the Dorsetshire coast, between the adjoining ports of Bridport and Weymouth.—*Times.* [Surely this calls for some remedy. Why are not ports of refuge established in different parts of our coast, as recommended by the Committee of the House of Commons? The utility of Ramsgate and Plymouth has now been fully established, but doubtless the absurd standing orders impede this branch of public enterprize, as they do others.]

Common Road Steam Carriages.—Sir James Anderson, an Irish baronet of peculiar ingenuity and extensive fortune, has completed a vehicle of this class, which will be placed, about ten days hence, upon one of the London roads, and is warranted to perform fifteen miles within the hour. Sir James's experiments to accomplish this object have been so costly, that upwards of 30,000*l.* were sunk on them some months ago.—*Irish paper.*

Waterloo Bridge.—A general assembly of the proprietors of Waterloo-bridge was held at the Crown and Anchor, Strand. Mr. Bredell, the secretary, read the last half-yearly report to the 23rd of August. The report stated that the select committee appointed, on the motion of Sir M. Wood, Bart., M.P., to consider the interests of the Waterloo-bridge proprietary as regarded the City Improvement Bill, had not come to any decision on which they could report. The soundings of the bed of the river had, since 1835, suffered but trivial variations, not exceeding six inches in any direction connected with the bridge, and the latter structure continued without the least defect. A gradual improvement has taken place in the receipts of the bridge. Mr. Plews observed that the approaches to the bridge contained an accumulation of water which had saturated the embankment, and would ultimately reach the abutments and wall of the bridge, if a remedy was not immediately applied. The chairman, in reply, said that the directors had arranged to abate the evil complained of in the early part of next spring.

Sea Ordnance.—At Woolwich Dockyard the workmen are busily engaged in enlarging the bores of 24-pounders for the purpose of lessening the weight of ordnance between four and five cwt., and at the same time enabling them to discharge a 32-pound shot and shell of the same calibre. This is in accordance with a plan some time since recommended by the late Lieut.-General W. Miller, R.A., and which will thus enable the guns to be worked with greater facility.—*Morning Advertiser.*

Hollow Shot.—The Prince George, which has been used to ascertain the effect of the hollow shot and shell fired from the Excellent, has been taken into the South Dock to be broken up. Her appearance sufficiently indicates the tremendous effect of these projectiles, as well as the skill and precision with which the scientific and practical course of instruction pursued on board the Excellent is arming our officers and seamen.

NEW CHURCHES.

Catholic Cathedral.—It is stated in a provincial journal to be the intention of the Roman Catholics to erect a magnificent cathedral in London, and that 100 wealthy peers and commoners are expected to subscribe 1,000*l.* each towards it.

Worcester.—It is in contemplation to build a church on the site of old St. Clement's, in the city of Worcester, to be called the Watermen's Church. This will, it is hoped, prove a great blessing to this hitherto much-neglected people.—*Ibid.*

New Church, Meltham Mills, near Huddersfield.—This church, dedicated to St. James, was opened on the 2nd instant. It is built upon a plan recommended by the bishop of Sodor and Man, and will seat 250 persons; and adjoining it is a school for 600 children, which, by means of sliding shutters, may be thrown open and form part of the church. It is in the Gothic style, by Mr. J. P. Pritchett, York.—It is handsomely finished inside, lighted with gas, and has an excellent organ, by Ward, of York. The expense, which was 4,000*l.*, was defrayed by Mr. James Brook, the mill-owner.—*Leeds Intelligencer.*

Trinity Church, Gray's Inn Road.—This church was consecrated on Thursday December 13th, by the Bishop of London.

Astbury Church Spire.—This venerable structure (which was struck by lightning in August last) the pride of the surrounding district, has been raised to its former beauty and elevation by Mr. Thomas Wallworth, architect and builder, of Congleton.

Brighton.—The new church of St. John the Evangelist, which, through the praiseworthy exertions and liberality of the rev. vicar, is now in course of erection on Carlton-hill, is already nearly roofed in; and, as the works proceed very rapidly, it is expected to be completed for divine worship in six months from the present time.—*Brighton Gazette.*

Preston.—The first stone of a new Catholic chapel was laid on the 3rd ult.

Birmingham.—A new church, named Bishop Ryder's Church, was consecrated on the 18th December. It was erected under the direction of Messrs. Rickman and Hutchins, architects. It contains 1,574 sittings, 813 of which are free. The whole expense of erecting the church amounts to about £4,300.—*Leamington Chronicle.*

PUBLIC BUILDINGS AND IMPROVEMENTS.

Statue to Huskisson.—At the meeting of the Liverpool Town Council, on the 5th, a letter from Mrs. Huskisson to the Mayor was read, requesting permission to place a statue to her late husband under the dome of the large hall of the new Custom House. A resolution was unanimously agreed to, acceding to Mrs. Huskisson's request.—*Morning Herald.*

Coutts's Banking House.—Vast improvements are now going on at Coutts's banking-house, in the Strand, under the direction of Mr. Hopper. Great altitude has been given to several of the offices, by the removal of the floors of the rooms above; iron staircases have been constructed, and the adjoining house, westward, has been thrown into the former extensive premises. Messrs. Price and Manby have fitted up their apparatus for warming the various offices.

Hounslow.—In consequence of the dark state of that portion of the Great Western-road which passes through the town of Hounslow, a public meeting of the inhabitants unanimously resolved to light the town with gas, the expense to be defrayed by a private subscription.

Buckingham Palace is filled with workmen, employed in the repair and improvements now in progress. A portion of the wall extending from the Mews to the Conservatory will be rebuilt.

Kensington Palace.—Considerable repairs are going on in this palace.

Western Literary and Scientific Institution.—A new lecture theatre is to be built at the back of the premises in Leicester-square, under the direction of Mr. Godwin, jun. The estimated expense is 1,000l.

Carlisle.—The progress of the spacious public buildings is most satisfactory; the lecture room, for 800 persons, is nearly completed, and over it an exhibition room 56 feet 6 inches by 46 feet 6 inches, is now being constructed.—*Carlisle Journal.*

New Custom-house, Liverpool.—The long pending question of the warming and ventilating the Long-Room of the New Custom-House, is set at rest by an order from the Treasury to Messrs. Price and Manby, to apply their patent apparatus, a description of which we gave in No. 10 of our Journal. The great extent of this room, and the approaches to it having together a cubic content of upwards of 521,000 feet will require considerable power to raise the temperature sufficiently, and at the same time insure perfect ventilation; but judging from the very successful application of the system to the Elgin and Egyptian Galleries of the British Museum, the work-rooms of the Indigent Blind School, and other buildings of equal extent, there can be little doubt of the desired end being obtained.

Taymouth Castle.—Workmen have been busy during the last summer and autumn in building a wing to this magnificent seat of the Marquis of Breadalbane, to correspond with that on the east side, which formed part of the original building. It is generally understood that the cause of the completion of the building at the present time is to be referred to no less than an expected visit of royalty. Rumour says that it is fixed, so far at least as such movements can be so, that our young Queen is to visit her ancient kingdom of Scotland next year; and in the list of noblemen's residences to be honoured by her presence Taymouth Castle occupies a distinguished place.—*Perth Courier.*

Improvements in Westminster.—Notices have been served upon the tradesmen and other persons occupying tenements between Westminster Abbey and Grosvenor-place, Pimlico, at the instance of the Westminster Improvement Company, who state in such notice that it is their intention to apply to Parliament in the ensuing session for leave to bring in a bill for forming certain new squares, streets, terraces, &c., within the said district, and requiring the person upon whom such notice is served to give his or her assent or dissent to the proposed proceedings on or before the 1st day of January, 1839.

A marble bust of Sheridan Knowles has just been sculptured by Mr. Tate, an artist of Newcastle, for some spirited friends in the north.

FOREIGN INTELLIGENCE.

Danube and Black Sea Canal.—The negotiations between Austria and Turkey are going on with vigour. Austria undertakes the direction of this important work, which is to commence a little below Rassowa on the Danube, close to C ornavoda, and will proceed thence in a straight line to Lake Lorazo, falling ultimately into the Black Sea at Kustendji, where a port is to be established.—*Franconian Mercury.*

Public Works, Egypt.—Mehemet Ali has held a divan, in which it is said that the continuation of the dams on the Nile was deferred for want of money. For the same reason the railway from Cairo to Suez was postponed, but its place was resolved to be supplied by a canal.—*Journal des Debats.*

Gas in the Orkneys.—The town of Kirkwall, in Orkney, is now lighted with gas, which now burns in the *Ultima Thule.*—*Morning Chronicle.*

Restoration of St. Ouen.—The municipal council of Rouen have just approved of the plans for the completion and restoration of the church of St. Ouen, one of the Gothic *chef d'œuvres.* The estimate is 1,400,000fr. or 10,000*l.*—*Morning Herald.*

Russia.—The rebuilding of the Winter Palace, on which several thousand workmen have been employed during the summer, proceeds rapidly, and externally it is nearly finished. The Emperor, who viewed it a few days ago, expressed himself fully satisfied with the progress of the work. It is said that the state apartments of the palace will be ready for use next Easter. The commission which was sent at the beginning of the year 1837 to Toflis, the object of which was to draw up the scheme of a reform in the several branches of the administration in the Transcaucasian provinces, appears to have terminated its labours. Baron Von Hahn, the president, and some other members of the commission, have lately arrived here from Teflis. At the end of last month the Cleopatra frigate, Captain Grey, arrived here from Cronstadt, having on board the Marquis of Clanricarde, the British Ambassador. Count Strogonoff has returned from his extraordinary mission to London.

To-day there is to be a brilliant parade of the Imperial Guards, and the newly erected triumphal gate at the barrier on the Moscow road will be inaugurated. Their Imperial Majesties, and the members of the Imperial Family, arrived yesterday from Zarskojeselo, to be present at both,

Haarlem Meer.—In the second chamber of the States General at the Hague, on the 12th inst., a Royal message was brought up with a project of Cour, for raising a loan to defray the expense of draining the Lake of Haarlem.—*Journal de Commerce d'Anvers.*

The Government has lately purchased in England two iron steam boats—the Inkermann and the Newka. The first is intended to ply between Constantinople and Odessa. It arrived at Odessa on the 9th of this month, having performed the voyage from London in 38 days. The Alexandria steam boat, which ought to have arrived here on Monday, is not here. To-day it ought to set out on its return to Lubeck. We learn here that it has been compelled by a storm at sea to put into Ballischport.—*Hamburgh paper.*

Vienna.—The church of St. Stephen's is to be wholly repaired, and we are happy to find the *Vienna Architectural Journal* contradict the report current in Germany that part of the spire was to be taken down on account of the inclination in the upper part being 3 deg. 3 min. This we believe was caused in the siege by the Turks, and we believe is no more productive of danger than the settling of Salisbury spire, or the vibration of our Monument. The Town House, at Prague, as interesting as a work of art as it is from its historical associations, is also to be fully restored and beautified. The Emperor Ferdinand has at his own cost repaired the romantic castle of Karlstein in Bohemia, one of the best works of the Cinque cento; and instead of being used as a powder magazine, it is to be converted into a museum or national Valhalla, like that at Munich.

Bridge at Presburg.—The engineers have chosen the locality for the permanent stone bridge over the Danube at Presburg, which is to form part of the Vienna and Raaber railway.

Engineering Prizes in Hungary.—The recent devastation of the city of Pesth by inundation has caused the public spirited Count George Andrassy, to offer munificent prizes for the best treatises on the history of these overflows of the Danube, and the means of averting them, and with a generosity worthy of their donor, they are thrown open to foreign competition.

Texas.—A company has been formed to establish a road for waggons, and to carry on trade from Galveston Island through Chihuahwa to Montery on the upper part of the Gulf of California. —*New Orleans paper.*

Egyptian Dock —M. Mongel, a French engineer, has arrived at Alexandria. The pacha has sent for him to confide to his care the construction of the repairing dock which Sahir Effendi commenced, but could not finish. M. Mongel's reputation leaves no doubt of his success. The viceroy has granted him 36,000 francs a year, and 2,000 for his lodging. If, as he has promised, M. Mongel terminates this work before three years, he is to have besides a gratuity of 60,000 francs.

Versailles Waterworks.—The king has appointed a Commission of engineers to inspect the waterworks at Marly, and to draw up plans for the better supply of Versailles with water.—*Galignani's Messenger.*

Suspension Bridges, Constantinople.—A French painter and architect, M. Hector Horeau, has drawn up the plan of a suspension-bridge, which is to open a new communication between Constantinople and Galata. It is to have several suspensions, and that of the centre is to be sufficiently high to admit of the passage of the largest vessels. The principle advantage of the construction will be to conciliate the naval movements with the public circulation. The plan, which is a sort of revival of that conceived by Michael Angelo for the same spot, is to be presented to the Sultan.

French Mail Coaches.—A decree has been issued authorising the Minister of Finance to pay 400,000 francs, or £16,000, for the establishment of the new mail coaches on the great roads of France.—*Moniteur.*

Quicksilver Mine.—We are informed by Mr. Cooper, that in boring near this place through the soft stone upon which this region of country is based, his auger, at the distance of several hundred feet from the surface, dropped into a lake of quicksilver, fourteen feet and some inches deep.—*Marengo Ala. Gazette.*

Paris.—The clearing away of the small houses surrounding the fine Tower of Saint Jacques la Boucherie appears to have been suspended. On the site of one of the porches of the church a reservoir is now forming for supplying the inhabitant of the adjacent quarters with filtered water.—In consequence of the frost nearly all kind, of masonry work has been suspended at Paris, and more than 15,000 workmen are, now out of employment in the capital.—*Galignani.*

Calais.—It is in contemplation to erect a new light-house at Calais, 200 feet high in the room of the Tour du Guet, which stands only 120 feet above the level of the sea. The precise spot of the new building is not yet decided upon, but a commission has been appointed to select the most eligible position.

The *Journal de Cherbourg* announces that the Minister of War intended to call for a credit of 10,000,000f. for the completion of the fortifications of Cherbourg and the establishment of a new powder magazine.

Greece.—The king has laid the foundation of a monument to Marco Bozzaris, at Missolonghi.—*Times.*

French Fortifications.—There are 121 fortified places in France, of which 21 are of the first class, 48 of the second, and 52 of the third.—*Times.*

Dutch Engineers.—The minister of the colonies, at the request of the governor-general of the French Indies, has published in the *Staats Courant* an invitation to the young officers of the Waterstaat who are unmarried, and if possible not above 26 years of age, to be employed in the colonial possessions, whither they will be sent, and in the first three years with salaries of 2 to 300 florins per month (20*l.* to 30*l.*), exclusive of other emoluments.—*Times.*

Australia.—The estimates of colonial expenditure for the year 1839 are, for roads, bridges, and streets, 25,970*l.* 2*s.* 6*d.*

The King of Bavaria has received, as a present from the Emperor of Russia, a vase of malachite, of extraordinary beauty and size, being twelve feet high with the pedestal.

Professional Press in Russia.—The government publishes the following :—Mining Journal, Engineering Memoirs, and Journal of Ways of Communication (roads and bridges). There is besides a Gazette of the Arts, published 48 times a year, with 100 engravings. Most of these are in French or German.—*Journal des Debats.*

Sleep on Railroads.—The following notice of an invention of accommodation " to sleep," as if at home, while travelling on railroads, appears in a recent number of the *Baltimore American*:—" The introduction of the newly-invented sleeping cars on our railroads makes that kind of travelling almost perfect—all that is wanting now is a dining car. The sleeping cars will soon be placed on the railroad between this and Philadelphia, so that travellers leaving here in the seven o'clock train may go to sleep in this city, and not be disturbed till they reach Philadelphia. These cars are fifty feet in length, and the seats, which are sideways, can, by a simple movement, be converted into *berths*; in each car forty-eight passengers can be accommodated with berths."

ANTIQUITIES.

Carthage.—Sir Grenville Temple has employed six months in executing excavations in the neighbourhood of the site of Carthage, and his labours have been rewarded by a variety of interesting discoveries. In the ruins of the temple Juno Cœlestis, at Ganath, the protecting divinity of Carthage, he found about 700 coins, different articles of glass, and earthenware utensils. But the most remarkable and unexpected of his discoveries has been that of a villa on the sea shore, and fifteen feet under ground. Eight chambers have been entirely cleared, and their form and decorations prove that the house belonged to some distinguished personage. The walls are painted, and the vestibule is paved in superb mosaic, in the same style as those of Pompeii and Herculaneum, and representing a variety of objects, such as marine divinities of both sexes, fishes of different species, marine plants, a vessel with women dancing on the deck, and surrounded by martial admirers, lions, horses, leopards, tigers, zebras, bears, gazelles, herons, and other birds. In the different chambers were found several human skeletons, supposed to be the remains of warriors killed during the storming of the villa. In another house Sir Grenville Temple has also discovered various interesting mosaics, representing gladiators combating wild animals in the arena, with the name of each combatant written over his head. In another part are represented horse-races and men breaking in young horses.—*Galignani's Messenger.*

A Roman Mosaic Pavement.—It will be remembered that Dr. Allnatt published a statement a few weeks since, which appeared in most of the public journals, of some ancient relics which had been discovered at Pangbourn, Berks, by the labourers employed on the Great Western Railway, and which were supposed to be of Roman origin. This supposition has received within the last few days further confirmation by the exhumation of an almost perfect floor of tessellated pavement, situated in a beautiful valley near the Thames, about two miles from the scene of the former discovery. It is conjectured to have been the floor in the chamber of a Roman villa. The pavement is formed of " quarries," or the small, irregularly square, detached tesseræ, so characteristic of Greek and Roman manufacture, and the figures are of the most elaborate and beautiful design. The ornamental portion, constituting the centre of the floor, is eight feet square, of four distinct colours, viz., red, gray, brown, and white. The colour appears to be formed of a species of fire-hardened cement laid upon the surface of the tesseræ, for it is superficial, and does not pervade its whole structure The discovery has excited much interest: a great many persons from distant parts of the country, artists, and scientific gentlemen, having visited the spot; they are unanimous in declaring the floor to be a beautiful and interesting specimen of ancient art. The site of the house (or, as some imagine it to have been, a military tent) can be traced with tolerable accuracy by the lines of mortar, charcoal, and flints, used in the foundation. Two human skeletons were lying exterior to the walls, near one of which a Roman coin was found, and by the side of the other a curious species of broadsword, which antiquarians suppose to be identical wi h that used by the auxiliary legions. Orders have been given by Mr. Brunel, the engineer, for the whole to be preserved entire.—*Times.*—[It is with great regret that we have since learned that Mr. Brunel has directed this interesting relic to be broken up. Messrs. Grissel and Peto, however, have had a drawing made, which is intended to be lithographed. We are sorry to see this disrespect for objects which are of universal interest to every man of education and refinement. Such deeds of barbarism have been but too frequent, and geologists have repeatedly complained of the ravages which have been committed through the negligence of the engineers. Very little expense would have restored this pavement, and it would have formed an interesting object in the waiting-room of the station. We do not see, indeed, why museums should not be formed at every station, illustrative of the geology of the line.—Editor C. E. & A. Jour.]

Irish Canoes.—A short time ago, when the water was drawn off, for the purpose of deepening a part of Lough Reavy, nearest the discharge pipes, three old canoes, of very antique appearance and construction, being apparently hollowed out of a single tree, were discovered imbedded in the mud. One has been conveyed to Lord Downshire's seat at Hillsborough; another is at Castle-Ward, the seat of the Bangor family; and the third is in the possession of Lord Roden at Tullymore.

The fine remains of the abbey of Savigny, near Mortain, in Normandy, have just been purchased by M. de Caumont, the well-known antiquarian, and will thus be preserved to the country.—*Galignani.*

MISCELLANEA.

Zincography.—The *Baltimore American* states, that a method has been invented of drawing on zinc, said to be very superior in effect to lithography. The mode of preparing the metal so as to fit it for the purpose is said to be a secret unknown but to one person in the country. In the process of stamping, a delicate pink tint is conveyed to the paper, by which the engraving is made to assume the appearance of drawing on chalk.

Sculpture.—The Duke of Devonshire, who was so liberal a patron of Canova has, during his present sojourn in Italy, added several fine productions of the chisel of Thorwalsden, Marchesi, and other living artists, to his already large and valuable collection of marbles.

Brighton Pavilion.—In the storm on the 2nd instant, at a quarter before twelve, a flash of lightning struck the pinnacle over the north gateway of the grounds, and carried a portion of it away, and shattered several panes of stained glass.—*Morning Post.*

Cheap Repairs.—A society has been formed at Paris for preserving and describing the French historical monuments of the middle ages. The economical labours of this patriotic association are well worth the attention of such as may be struggling to resist the havoc of time and man. In their accounts, which we have before us, we find that with a sum of only 68*l.* they congratulate themselves upon having, in six months, repaired the churches of the Lot and Auvergne, those of Montrezor, St. Louis, du Pré, and Beaulieu, the Chateau of Langeais, the Priory of Morlange, the tombs of Oiron, and stained glass of Pont-Audemer.

The tolls of the Andover and Basingstoke turnpike have been let at an increase of upwards of two hundred pounds per annum, in consequence of the additional travelling through Andover, occasioned by the partial opening of the London and Southampton Railway.—*Wilts Independent.*

Seyssel Asphalte.—The Seyssel Asphalte property is occupying the gentlemen of the long robe in France, and it appears doubtful from what has transpired whether there existed any right to transfer it to a company. It is very unfortunate that this was not found out earlier, as, whatever may be its other applications, the asphalte has paved the way to much gambling and serious misfortune to the shareholders. No mines of gold, silver, nor copper, ever excited more sanguine speculation.—*Ibid.*

Heart of Oak.—One of the piles used in the foundation of the old bridge at Lancaster was taken out a short time since, and found to be "as sound as an acorn," although it must have been under water at least 900 years.

Preservation of Sculpture.—Experiments are in progress at the Ecole des Beaux Arts at Paris, with some oily substance to be used for the preservation of marbles and works of art, which suffer so much in the wear and tear of a great metropolis.—*Galignani's Messenger.* [We do not know whether this is one of our neighbours' reinventions of old English inventions anew; but some years ago Henning, the sculptor used a coating of wax on the triumphal arch in the Park, and hitherto with complete success.]

The newly invented light of M. Gaudin, on which experiments were recently made at Paris, is an improved modification of the well-known invention of Lieutenant Drummond. While Drummond pours a stream of oxygen gas through spirits of wine upon unslaked lime, Gaudin makes use of a more ethereal kind of oxygen, which he conducts through burning essence of turpentine. The Drummond light is fifteen hundred times stronger than that of burning gas; the Gaudin light is, we are assured, by the inventor, as strong as that of the sun, or fifteen thousand times stronger than gas, and of course ten times more so than the Drummond. The method by which M. Gaudin proposes to turn the new invention into use is singularly striking. He proposes to erect, in the island of the Pont Neuf, in the middle of the Seine and centre of Paris, a lighthouse five hundred feet high, in which is to be placed a light from a hundred thousand to a million gas pipes strong, the power to be varied as the nights are light or dark. Paris will thus enjoy a sort of perpetual day; and as soon as the sun of the heavens is set, the sun of Pont Neuf will rise.—*Mechanics' Magazine.*

NEW PATENTS.

LIST OF ENGLISH PATENTS GRANTED BETWEEN THE 26TH NOVEMBER, AND THE 24TH DECEMBER, 1838.

JOHN SMALL, of Old Jewry, Merchant, for "Improvements in the Manufacture of Thread or Yarn, and Paper, by the Application of certain fibrous Materials not hitherto so employed."—1st December; 6 months to specify.

PETER TAYLOR, of Birching Bower, in the County of Lancaster, Rope Maker and Slate Merchant, for "Improvements in Machinery for propelling Vessels Carriages, and Machinery, Parts of which Improvements are applicable to raising of Water."—1st December; 6 months.

AMBROSE BOWDEN JOHNS, of Plymouth, Artist, for "Improvements in colouring or painting Walls and other Surfaces."—1st December; 6 months.

JAMES HARTLEY, of Bishop Wearmouth, Glass Manufacturer, for "Improvements in the Manufacture of Glass."—1st December; 6 months.

THEODORE COTELLE, of the Haymarket, Civil Engineer, for "Improvements in Extracting the Salt from Sea or Salt Water, and rendering it pure or drinkable, and in Purifying other Water."—1st December; 6 months.

JOHN PLAYER, the younger, of Longhor, near Swansea, Glamorgan, for "Improvements in Furnaces and Fire-places, for Consuming Anthracite and other Fuel for generating Steam, Evaporation, Smelting and Heating Iron and other Metals."—1st December; 6 months.

WILLIAM PONTIFEX, of Shoe Lane, in the City of London, Coppersmith, for "Improvements in Apparatus and Materials employed in Filtering and Clarifying Waters and other Liquids."—1st December; 6 months.

JOHN McCURDY, of Tonbridge Place, New Road, Esquire, for "An Improved Method or Methods of Generating Steam and applying the same to the Evaporation and Boiling of Fluids, which Method or Methods is or are applicable to Steam Engines and other Purposes where Steam is or may be applied."—1st December; 6 months.

STANISLAUS DARTHEZ, of Austin Friars, in the City of London, Merchant, for "Certain Improvements in the Construction and in Arrangement of Axles, Axletrees, and the Naves of Wheels for Carriages."—1st December; 6 months.

JOHN SHAW, of Glossop, Brass Worker, for "Certain Improvements in the Arrangement and Construction of Wind Musical Instruments."—1st December; 6 months.

LUKE HEBERT, of Camden Town, Civil Engineer, for "An improved Mode or Modes of Fastening Trowsers and other Parts of Dress or Apparel." Communicated by a Foreigner residing abroad.—1st December; 6 months.

DANIEL CHANDLER HEWITT, of Store Street, Bedford Square, Professor of Music, for "Certain Improvements in Musical Instruments."—6th December; 6 months.

JOHN CHISHOLM and MARIN HYPPOLITE BELLENOIS, of Pomeroy Street, Old Kent Road, Manufacturing Chemists, for "Improvements in treating Massicott, Litharge, and other Compounds of Lead, for the Purpose of obtaining therefrom Silver and certain other Products."—6th December; 6 months.

GODFROY CAVAIGNAC, of Tavistock Row, Covent Garden, Gentleman, for "Improvements in Apparatus for transporting Materials for various Purposes from one Place to another, particularly applicable to Road Cutting and other Embankments."—6th December; 6 months.

THOMAS SWEETAPPLE, of Cotteshall Mill, Godalming, Papermaker, for "An Improvement or Improvements in the Machinery for Making Paper."—6th December; 6 months.

FREDERICK NEVILLE, of Pancras Lane, in the City of London, Gentleman, for "An improved Method or Process of Manufacturing Coke, whereby the Sal-ammoniac, Bitumen, Gases, and other resident Products of Coal are, at the same time, separately collected, and the Heat employed in the Process is applied to various other useful Purposes."—6th December; 6 months.

MILES BERRY, of Chancery Lane, Patent Agent, for "Improvements in the Means of, and Apparatus for, Manufacturing Gaseous Liquids, and for filling Bottles and other Vessels used for holding the same, and retaining the contents therein, and applying the same when required." Communicated by a Foreigner residing abroad."—6th December; 6 months.

JAMES CARSON, of Liverpool, Doctor of Medicine, for "A new Mode of Slaughtering Animals intended for human Food."—12th December; 6 months.

THOMAS ROBINSON WILLIAMS, of 61, Cheapside, Civil Engineer, for "Certain Improvements in Machinery for Spinning, Twisting, or Curling, and Weaving Horsehair, and other Hairs, as well as various fibrous Substances."—12th December; 2 months.

HENRY COUNT DE CROUY, of Picardy, in the Kingdom of France, now residing at 14, Cambridge-street, Edgeware Road, for "Certain Improvements in Filtration." Communicated by a Foreigner residing abroad.—12th December; 2 months.

JOHN ALEXANDER ELEAZAR DESGRAND, of the Boulevart du Temple, Paris, now residing in Paul's Chain, in the City of London, Civil Engineer, for "Improvements in the Production of Motive Power, and in Machinery, for applying the same to useful Purposes."—12th December; 6 months.

JAMES GARDNER, of Banbury, Ironmonger, for "Improvements in cutting Swedish Turnips, Mangel Worzel, and other Roots used for Food for Sheep, horned Cattle, and other Animals."—12th December; 6 months.

THOMAS VAUX, of Woodford, Land Surveyor, for "Improvements in Tilling and Fertilising Land."—15th December; 6 months.

CROFTON WILLIAM MOAT, Putney, for "An improved Mode of applying Horse Power to Carriages on ordinary Roads"—17th December; 6 months.

BARCLAY FARQUHARSON WATSON, of Lincoln's Inn Fields, Solicitor, for "Improvements in Crushing or Preparing New Zealand Flax."—17th December; 6 months.

EDWIN EDWARD CASSELL, of Millwall, Poplar, for "Improvements in Lamps."—17th December; 6 months.

JOB CUTLER, of Lady Poole Lane, Birmingham, Gentleman, for "Improvements in Combinations of Metals applicable to the making of Tubes or Pipes, and to other Purposes, and in the Method of Making Tubes or Pipes therefrom, which improved Method is applicable to the Making of Tubes or Pipes from Certain other Metals and Combination of Metals."—17th December; 6 months.

JAMES LEES, of Salem, near Oldham, in the County of Lancaster, Cotton Spinner, for "An Improvement in the Machinery for Spinning, Twisting, and Doubling Cotton, Silk, Wool, Hemp, Flax, and other fibrous Materials."—17th December; 6 months.

JOHN HAWKSHAW, of Manchester, Civil Engineer, for "Certain Improvements in Mechanism or Apparatus applicable to Railways, and also to Carriages to be used thereon."—17th December; 6 months.

BENJAMIN GOODFELLOW, of Hyde, in the County of Chester, Mechanic, for "Certain Improvements in Machinery or Apparatus for Planing or Cutting Metals."—18th December; 6 months.

JOHN ROBERTS, of Manchester, Machine Maker, for "Certain Improvements in Machinery or Apparatus for Planing or Cutting Metals."—18th December; 6 months.

JOHN RADCLIFFE, of Stockport, Machine Agent, for "The Application of an improved Covering for the Rollers used in the several Processes of Preparing Drawing, Slubbing, Roving, Spinning, Twisting, and Doubling of Wool, Cotton Wool, Flax, Silk, Mohair, or any other fibrous Material or Substance, or so many, of such Rollers as require, or are deemed to require covering for such several Processes, or any of them."—19th December; 6 months.

JOSEPH ZAMBEAU, of St. Paul's Churchyard, Chemist, for "Improvements in Rotatory Engines." Communicated by a Foreigner residing abroad.—19th December; 6 months.

ANDREW SMITH, of Princes Street, Leicester Square, Engineer, for "Certain Improvements in Apparatus for Heating Fluids and Generating Steam."—20th December; 6 months.

SAMUEL PARKER, of Argyle Place, Lamp Maker, for "Improvements on Stoves."—20th December; 6 months.

CARL AUGUSTUS HOLM, of Mincing Lane, Engineer, and JOHN BARRETT, of Vauxhall, Printer, for "Certain Improvements in Printing."—20th December; 6 months.

DANIEL STAFFORD, of 25, St. Martin's-le-Grand, in the City of London, Gentleman, for "Certain Improvements on Carriages, being an extension for the term of seven years, from the 24th day of December."—21st December.

ERRATA.

In the last number, page 403, in the description of Roe's patent water closet basin there is an error in lines 10 and 11; it states that "this chamber is *always kept* charged with water;" it should read, "the chamber is *only* charged with water when the handle is lifted, the water *at the same time being* discharged all round the basin."

Page 405, in the rule for converting French measure, line 9, describing the method of reducing francs into pounds, instead of "*add* two figures," read "*cut off* two figures."

TO CORRESPONDENTS.

Our correspondent respecting Dover Harbour, will hear from us by post.

Our correspondent at Carmarthen is informed that there is no defined dimension for slating called "*Queen's*"—both Queen's and Rag's vary in size from two to four feet in length, and from 18 inches to three feet in width; the average size is 36 inches by 24 inches; they are sold by weight, and not by the thousand.

"One of the Public" will be noticed next month.

We cannot notice Prospectuses of Companies at length, unless paid for as advertisements.

Subscribers are particularly requested to complete their sets of numbers for the first volume immediately.

We shall feel obliged to the profession if they will forward us accounts of works in progress, new inventions and discoveries; and particularly if our country subscribers will send us any newspaper containing any matter relative to the objects of our Journal.

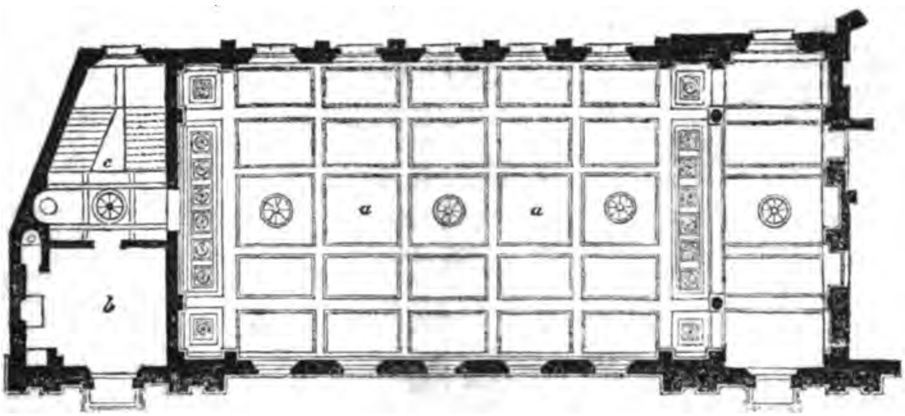
Books for review must be sent early in the month; communications prior to the 20th; and advertisements before the 26th instant.

*** The first volume may be had bound in cloth, and lettered in gold, price 17s.

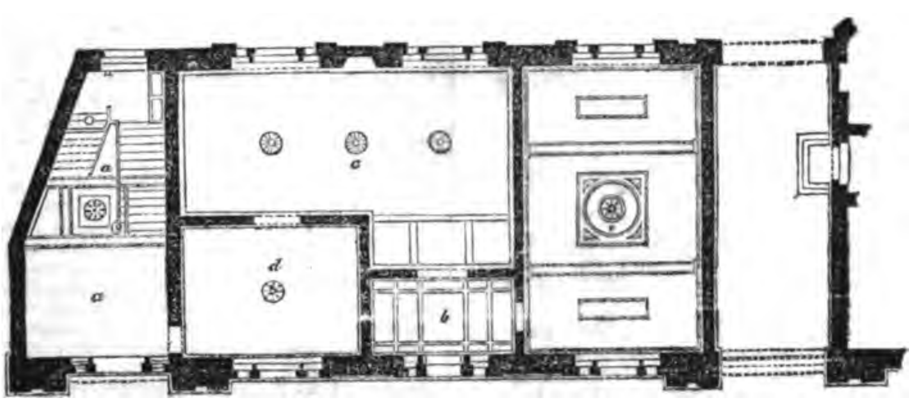
THE ATHENÆUM, AT DERBY.

ARCHITECT, R. WALLACE, ESQ.

ELEVATION.



PLAN OF THE UPPER OR PRINCIPAL FLOOR.



PLAN OF THE GROUND FLOOR.

Scale of Drawings, 20 Feet to the Inch.

THE ATHENÆUM, &c., AT DERBY.

The "Companion to the Almanac" has already given a general view of the four buildings of which the Athenæum forms one, and a tolerably full description of them; yet although we have so far been anticipated by that publication, what is there said rather invites us to give further particulars respecting those spirited improvements than not, more especially as we are enabled, through the kindness of the architect, Mr. R. Wallace, to exhibit an elevation and plans of that portion of the design which has most architectural pretension and character, namely, the Athenæum.

As our wood-cut renders verbal description unnecessary, all that we need explain in regard to it is, that the blank space or opening in the lower part of the right-hand pavilion or wing is the covered gateway leading to the inn-yard at the rear of the building (as is shown in the ground plan), where is seen one of the entrances into the Hotel. Hardly, therefore, need we observe that the latter building immediately adjoins the Athenæum on that side, being divided from it below only by the covered passage or gateway between the two; but we should explain that both entablatures of the separate façade here shown are continued through the two fronts of the Hotel, so as to keep up a certain general uniformity of appearance, although the Athenæum forms a distinct composition. Indeed, further than the regularity thus produced by the continuation of the principal horizontal lines and mouldings, and that of the style adopted, there is little similarity; the elevations of the hotel presenting two ranges of windows above, the lowermost of which, or those of the first floor, rest upon a socle immediately above the cornice to the basement. Besides which, there is a series of smaller windows in the attic, which is somewhat lower than that in centre of the elevation here given. Consequently that portion of the entire line, or the south side facing Brook-street, has more of the dwelling-house appearance, while the Athenæum distinguishes itself by presenting what our French neighbours term a *monumental* character; to which both the disposition of the windows and the great proportion of solid wall contribute in no small degree. In this respect alone the design exhibits some novelty and piquancy, particularly in the centre compartment, where the three openings below and the five above them produce a good architectural contrast; though the effect would have been better still could the width of the two lower windows have been limited to that of their middle openings, because at present they extend too closely to the angles, where the adjoining antæ at the breaks indicate an inner wall, although, in regard to the rooms within, the windows are unexceptionably placed, as is apparent from the ground plan. The upper part of this centre compartment is well imagined—solid and unbroken, yet without either blankness or heaviness. The chief objection to be made to it is, that the cornice of the upper order is too poor and scanty—in fact, is only a repetition of that to the basement floor, whereas greater richness was here demanded, if only to bring it into keeping with the architrave beneath it, more especially as the depth of this latter is considerably increased by the mouldings of the antæ being continued immediately beneath it. We are bound to observe, however, that the projection of the upper facia and cymatium of this architrave have been greatly exaggerated by our wood engraver. The two pavilions or extreme compartments are pleasingly treated, and these features bear some general resemblance to the similar ones of the new Corn Exchange, Mark-lane, but by no means to such degree as to incur the charge of plagiarism. The tripods at their angles, through which the chimney-flues are brought, produce an excellent effect.

In the plan of the ground floor, *a a*, are the separate entrance vestibule and staircase leading to the Athenæum Hall above; *b*, the vestibule, to the library *c*, and news-room *e*. The former of these, which measures 36 feet by 16, or 21 at the widest end, opens into a smaller room *d*, appropriated as a reading room. The news-room *e* is 30 feet by 19.

The upper floor is, with the exception of the room *b*, which serves both as a committee-room and a cloak-room for ladies, entirely occupied by the Athenæum Hall, which extends over the gateway, whereby its total length becomes 69 feet by a width of 30 feet 6 inches and 23 feet in height.

While the general symmetry is well preserved, the apartment acquires not only much pleasing architectural variety in its plan, but apparent, as well as real, extension, by the addition of the division over the gateway. At the same time we are of opinion that it would have been an improvement had there been four columns at that end instead of two, so as to form four lesser intercolumns (of the width of those between the columns and antæ on each side) and a wider one in the centre. Such a screen of pillars would have made the two divisions more distinct to the eye, yet would by no means have separated them too much, or occasioned a crowded appearance, or obstructed the view of the fireplace at that end; for the centre intercolumn would have been 7 feet 6 inches wide, and the others nearly 5; whereas the distance from column to column is now 19 feet, which must be equal to the height of the columns themselves, if not more. Another thing that would have been an improvement would have been to remove the doors at that end of the hall further from the fireplace, putting them into the extreme inter-pilasters, so that one would have opened immediately into the card-room, the other (as at present) into the supper-room.

Judging from the plan, the back front of the Athenæum, appears to be of architectural design, although it only faces the inn-yard of the Hotel: at least the pilasters between the windows seem to indicate that such is the case; and, if it really be so, we think the cost so bestowed might have been better applied; more especially as that side of the building appears to be quite shut out from view by other buildings abutting on that angle of the Athenæum, where the staircase is placed, and in consequence of which the architect has been compelled to adopt a very irregular and inconvenient form for the staircase; whereas only four or five feet more at that angle would have greatly improved that approach to the Athenæum Hall. Above the hall is another room of the same dimensions, although considerably lower, which is lighted from above, and intended to be fitted up as a museum.

REVIEWS.

Observations on Limes, Calcareous Cements, Mortars, Stuccos, and Concrete; and on Puzzolanas, Natural and Artificial; together with Rules deduced from numerous experiments for making an Artificial Water Cement, &c. By C. W. Pasley, C.B., Colonel in the Corps of Royal Engineers, F.R.S., &c. London: John Weale, 1838.

We are indebted to Col. Pasley for this practical work, and for an admirable example of how theory may be applied as the assistant of practice. Cement has long since attracted a greater attention than stone itself, and many have longed for that power which enabled the Romans to make such durable works from materials so fragile. Col. Pasley has devoted himself to his task with an energy and application which have secured equal honour to himself and value to his admirable work. Few men immersed in professional labour have the time to follow up such subjects in a proper manner, for it is only from a connected series of experiments that success can be obtained.

The work now before us is the result of many years' labour and study, and enters elaborately into the examination of materials employed in building, and the cements used to unite them. He gives at great length his experiments on their strength and durability, and also on the quality of substances for forming limes and cements. He thus throws great light on the principles of construction, and enables us to ascertain the properties of the materials, the components of the mortars and cements, and the proportions in which they should be amalgamated. This is an important service rendered to the Architect and the Engineer, and gives the work a character of interest which we doubt not will be appreciated by our readers.

We make our first selection from the dissertation on limes, which conveys some judicious remarks on mortars :—

> We found by repeated experiments at Chatham, that one cubic foot of Halling lime weighed nearly the same when fresh from the kiln, and by the gradual addition of water that it dilated to the same increased bulk, in the state of quick-lime powder, but when worked up into mortar not too short for use, that it would not bear quite so large a proportion of sand as the common chalk lime had done. This experiment leading to a result in opposition to a common opinion amongst the builders of the metropolis, which is that the Dorking and Halling limes, as being stronger limes, will, when made into mortar, bear more sand than common chalk lime, I was induced to examine the principle upon which they found this opinion, which on consideration appears to me to be erroneous; because these two limes and all the other hydraulic limes are undoubtedly in an intermediate state between pure lime which is the weakest, and the water cements which are the strongest, of all calcareous cements: and every one will acknowledge that the proportion of sand, which will make good mortar with chalk lime, would entirely ruin cement, which if scarcely capable of bearing one third of that quantity. Hence it follows that the hydraulic limes ought not to admit of so much sand as chalk, but that they will bear more than cement, without being injured.
>
> Accordingly I conceive that three cubic feet of sand to one of Dorking or Halling lime, will be a good proportion for making mortar with those limes, which approach very nearly to pure lime. The water required will be nearly one cubic foot, and the quantity of mortar produced will be about two cubic feet and nine-tenths, being rather less than the original space occupied by the sand alone.

But the blue Lias lime will not make good mortar if mixed with more than two cubic feet of sand to one of lime. This opinion first formed by me from analogy, and in consideration of the blue lias approaching very nearly to a water cement, proved on due enquiry to be borne out by, and exactly conformable to, the practice of the masons of Lyme Regis. But Captain Savage of the Royal Engineers, who was employed professionally some years ago in improving the Cobb or Pier of that little seaport, which was done by tide work, and in which no other kind of lime was used, assured me that he found that a smaller proportion of sand than 2 to 1 made still better mortar. We have since ascertained by repeated experiments at Chatham, that 1 cubic foot of blue lias lime from the kiln weighing 47lbs., mixed with 2 cubic feet of sand, and about 3 quarters of a cubic foot of water, made mortar fit for use, but which could not have borne more sand without becoming too short. The average quantity produced was two cubic feet and one fifth, which contrary to the result obtained with the purer limes, occupied more space than the sand alone originally did. We found also that blue lias lime from the kiln, like all the other limes that we experimented upon, filled only about two thirds of its original measure, when reduced by pounding to the state of quick lime powder; but one cubic foot of blue lias lime when slaked, only dilated into one cubic foot and a third of slaked lime powder, not including about one eighteenth part of a cubic foot of core, which we threw away. Hence it expands less by slaking than either chalk lime or Halling lime.

The Colonel very justly attributes the *modern* introduction of concrete for foundations to Sir Robert Smirke, who first used it at the Penitentiary, Milbank, London. The Colonel remarks that :—

Neither gravel without sand, nor sand without gravel can form good concrete. The large pebbles composing the former, if mixed with quicklime powder and water would only be cemented together by lime paste, or as it is technically termed *lime putty*, filling up the large interstices between them, which is known to be the weakest form of lime. On the other hand, fine sand alone would produce nothing better than a mass of common mortar, which has very little strength in itself, but is excellent for cementing larger materials. The proportions of the gravel and sand used are of little importance, provided that the former be rather large, and the sand sufficient to fill up the interstices in it, for which purpose a mixture of coarse and of fine sand is better than one sort only. But no such mixtures are necessary, in using the sandy gravel of many parts of the Thames, where it is found in the state most suitable for making good concrete, and is employed both for this purpose, and as ballast for shipping.

It being known that clean gravel and sand when put dry into any measure, will almost immediately settle to a lower level on the addition of a certain quantity of water, and it being a matter easily proved that no ramming can possibly compress them afterwards, it appears to me, that the proportion of lime used in concrete should be just sufficient to combine with the gravel and sand in this compact state; that is after the violent action of slaking shall have subsided, which causes a temporary expansion, that is counteracted whilst in operation, but the usual process of treading down or ramming concrete.

Examples are given of several buildings in which concrete has been applied in the formation of the external walls, and the Colonel shews by their failure the impolicy of this mode of construction, however strongly he recommends its adoption for foundations.

The composition, commonly called Roman cement, has within the last few years been employed pretty extensively in the metropolis for building purposes, and has certainly greatly contributed to the extension of external decoration. A prejudice, however, still exists against its application for ornament in our churches and public buildings, which may have arisen from an improper use of it, and from the frauds of some of the manufactures, but the general result has been to convince us strongly of its applicability for these purposes. In our opinion, if of good quality and properly worked in the mixture with sand, it is of equal durability with Bath stone, and capable of employment for the same objects. An unfortunate prepossession against its application to ecclesiastical structures seems to prevail, even as if a mandate of interdiction were issued against it, although it would most certainly materially assist the architect in giving some character and decoration to these edifices. Neither would its expense be such as to call for a great increase of the penurious allowances of the church commissioners, who show as niggardly a spirit in these respects as if they wished to imitate the union workhouses. It would be well if the architects generally could prevail upon the proper authorities to allow its introduction, which we are sure could not fail to afford gratification to the public. It is only necessary to guard against the application of inferior preparations, and this could be fully secured by providing in the specification that the cement should be procured from competent manufacturers, which the architect may appoint.

We found by experiment at Chatham, that two thirds of a cubic foot of calcined Sheppy cement powder, which is equivalent to one cubic foot of cement from the kiln, would not bear much more than one cubic foot and one third part of a foot of sand, without evidently becoming too short for building purposes. This is equivalent to a mixture of two measures of sand to one of cement powder. But experience has shown that even this proportion of sand is too great in practice, for the builders of the metropolis, who have used immense quantities of the Sheppy and Harwich cements for many years, agree that more than 5 parts of sand to 4 of cement powder, or 1¼ measure of the former to one measure of the latter, injures the cement, by retarding its setting and rendering it too friable, whether used as mortar for walls, or as stucco for the fronts of houses; but they consider that equal parts of sand and of cement powder, involving a smaller proportion of the former ingredient, are still better.

But not to lose sight of the just comparison between cement and lime, these proportions, when stated in the same manner as we did in treating of lime, imply that whilst one measure of cement from the kiln will not bear more than two thirds or at the utmost five sixths of a measure of sand without injury, one measure of the various sorts of lime from the kiln, according to its quality, will bear two or three measures of sand or even more.

There are two properties of cement, which ought to be thoroughly understood.

First. It only sets rapidly when made up into small balls or in very thin joints. In large masses or in thick joints, the rapid induration takes place near the surface only, from whence it extends towards the centre so very slowly, that the cement there may remain in an imperfect state for a very long time. This property it has in common with lime mortars and concrete, which when in mass set more slowly at the centre than at the surface, in the like proportion (33).

Secondly. As was before remarked in article 42, cement is always weakened by sand, no matter how small the proportion of that ingredient may be, so that if both materials were equally cheap, it would be best to dispense with sand altogether in using cement as mortar for building walls, but not in using it as stucco for plastering the fronts of houses.

Numerous experiments have convinced me of the truth of these maxims, which any of my readers may easily verify. In respect to the latter in particular, take a small quantity of the best cement powder, mix it with three or four times its bulk of fine sand and make it up into a ball with water, and you will find that instead of setting, it will either remain quite friable or crumble to pieces, both under water and in air.

Upon the whole cement sets most quickly, and unites itself most powerfully to bricks or stones, when it is perfectly pure or unmixed with sand, provided only, that the joints be thin, I should say not exceeding half an inch in thickness. For this reason, in forming cement into chimney pots, copings, &c., where the general thickness much exceeds the above dimension, and consequently where pure cement alone would not make sound work, instead of frittering away its strength with sand, I would recommend fragments of broken tiles or gravel, to be mixed with it, the interstices of which are such as to allow the pure cement which fills them, sufficient body to attain a due degree of strength, without being quite so large as to retard its setting, and thereby cause weakness in the central parts of those spaces.

Among other interesting illustrations of the powers of cement, the Colonel has fully proved its great strength when applied as a joint for stone-work. One of these experiments was made upon two blocks of Bramley-fall stone, each 39 inches long, 29 inches broad, and 26 inches deep, weighing about 2662 lbs. The beds or contact surfaces of the stones at the joints were roughed over by picking down the surface; they were then united with some of Messrs. Francis & Son's best Roman (*English*) cement, composed of a mixture of Sheppey and Harwich cement stone. Six weeks after, the experiment was continued by suspending the upper stone, and loading the under one with weights, to the enormous extent of 36,544 lbs. without breaking the joint. This was then split by means of a mallet and chisel, when, to the Colonel's astonishment, it was found that with the exception of the outer part of the cement, which had been exposed to the air, and was extremely hard, the whole interior of the cement joint was softish, and neither resisted the action of the thumb-nail nor of a sixpenny piece on edge, which scored the surface to the depth of nearly a sixteenth of an inch. From this and other experiments, the Colonel deduces the importance of the "*application of cement in masonry, even in the union of the largest stones.*"

The author gives some experiments on the strength of stone, which we think will be found serviceable to the architect and engineer in the choice of this material :—

As the value and importance of artificial stone used for the walls of buildings, or for those of wharfs or docks, must depend upon its strength in opposition to a breaking weight, it now appeared desirable to ascertain its resistance in competition with that of the common building stones of this country, as well as with that of bricks and of pure chalk from the quarry, for which purpose I caused a number of similar small prisms, each four inches long and two inches square, to be cut out of all those substances, which being subjected to the proper breaking apparatus, yielded the results contained in another Table, No. VIII., and, in order to render this more complete, the cohesiveness of the same stones has been repeated from Table III., whilst that of well-burned bricks and of inferior bricks has been estimated, from the average of the strongest and some of the weakest results, recorded in Tables I. and II.

Table VIII.—Comparative Resistance of various Natural Stones, Bricks, and Chalk, reduced to Square Prisms of the same dimensions as the small Artificial Stones before Experimented upon, with their comparative Cohesiveness also.

In our next Journal we intend to continue our remarks upon this excellent work, and to give some farther extracts; and in the meanwhile we cannot too strongly recommend to the profession the utility of examining this work for themselves. We do not pretend to offer a substitute for the works which come under our notice, but rather to enable our readers to form such opinions as may guide them in their use and selection. It is as much as we can do in some cases of such extensive scientific works, to afford even a specimen; but in case of works like Colonel Pasley's, it would be indeed the old Greek story of offering a brick as the pattern of a house, to attempt to condense such important materials.

Westminster Improvements: A Brief Account of Westminster, with Observations on Plans of Improvement. By One of the Architects. London, 1839.

This small volume is designed to call attention to the plans of the author, as adopted by the Westminster Improvement Company, and is therefore necessarily subservient to that object. It contains, however, some interesting matter as to the site of Westminster, its levels, and its drainage, and some agreeably-written antiquarian matter.

The basis of Mr. Bardwell's plan is, that it shall be conducted on a large scale, so as to insure the thorough drainage of the district, which certainly cannot be effected by the piecemeal operations which are now adopted. Any change either in the population or the salubrity of the district in question, cannot fail to do some good, and the proposition is extremely opportune in the present state of the Houses of Parliament. We think, that in this consideration care should be taken not to mar the splendid mass of gothic which we shall soon possess, and this induces us to demur a little to Mr. Bardwell's admiration of the Italian styles. This comes strangely indeed from one who, in the early part of his book, evinces such a love for Edward the Confessor, and such a yearning for the preservation of St. Margaret's.

Considering the object of the work, we are not entitled to expect perfection, and we are therefore not very much astonished at an infusion of egotism, which prevails towards the conclusion of the book. We dissent, however, from Mr. Bardwell in some few of his opinions, and to some of these we beg to call his attention. We cannot see how the insalubrity of London can increase the fogs, for indeed if they arose from land miasma, they ought rather to have diminished from the draining and clearing of the metropolitan districts. He obliges us with a lengthened enumeration of the many causes of London unhealthiness, but he totally omits to state that London is one of the healthiest cities in the world, and that the average of human life has rapidly increased in value. We rather doubt also that our Saxon ancestors were the founders of the civilization of modern Europe, however much we might wish it, and we should recommend our readers to peruse this statement "cum grano salis." Mr. Bardwell may remember in what state Alfred found England after the time of Bede, and how France sank subsequently to the labours of Charlemagne and Alcuin. We dissent also from him as to St. Margaret's being a vestige of Edward the Confessor, and we cannot see any claim of antiquity which can be urged against its removal. The epithets applied to Westminster strike us also as rather incongruous, for we cannot see what resemblance it has to the Isle de la Cité, the Palatine Hill, or the Acropolis, nor what it has to do with the στοά βασιλική. "Lucus à non lucendo."

Public Buildings erected in the West of England; as designed by John Foulston, F.R.S., B.A. Quarto, 117 Plates. J. Williams. London, 1838.

This is almost the only work of the kind which has appeared in this country for several years, for, with the exception of Laing's, containing the Custom House, and some other buildings erected by him, we are not aware that any architect has published his own executed designs, although it used formerly to be by no means an uncommon practice among professional men. Gibbs, Adam, Paine, &c., for instance, published the plans and other drawings of all their principal edifices, and that at a time when architecture was comparatively little studied. It is all the more singular, therefore, that such custom should have been laid aside precisely at the time when architecture itself has become more prolific than it was during the last century, and when structures of very varied design are rising up yearly, if not daily, not in the metropolis alone, but in almost every provincial town of any note, and, in fact, almost all over the country. Whether it be that, notwithstanding the very increased scope and demand for architectural embellishment, there exists less demand than formerly for studies in design, both on the part of the profession and of private individuals, we undertake not to decide; but it certainly does look like a very anomalous fact, that such should be the case, let the cause be what it may. We could, indeed, make two or three guesses at the latter, one of which is, that those who have done most and best are not particularly anxious to bring out their designs as studies for the benefit of others; while those who have been less favoured by opportunity have not done enough to enable them to come before the public with a collection of the kind. Another reason, perhaps, is that, although greatly more has been done within the last twenty or thirty years than in the course of the whole of the preceding century, out of that number of buildings there are comparatively few that rise above a certain average standard of merit; consequently few that the public would care to have geometrical drawings of. Or, it may be that we are now so accustomed to behold decorated fronts, porticos, and other architectural embellishments, as to regard them as mere matters of course, and deserving no more than cursory inspection. Or else—but we will put an end to further conjecture; for even could we hit upon the real cause, it would be idle to expect that any thing we could say would tend to remove it. What may be taken for granted is, that there is no demand—we mean no adequate demand—for works of this description, else, doubtless, as is the case with all other produce, whether manual or mental, it would be followed by supply.

At all events, we bid welcome to the solitary "stranger" now before us, and not the less heartily because he comes from the provinces—from Devonshire and Cornwall, where, at Plymouth, Devonport, and other places, Mr. Foulston has erected not a few public and private buildings. Nor can we do better than give, before we proceed further, a list of those which form the subjects contained in the volume:—

Plymouth—The Hotel, Assembly Rooms, and Theatre, 47 plates; the Athenæum, 6 do.; Public Library, 5 do.; St. Andrew's Chapel, 8 do.; Do. Church, 8 do.; Exchange, 4 do. *Devonport*—Town Hall, 4 plates; Commemorative Column, 5 do.; Civil and Military Library, 5 do.; Mount Zion Chapel, 4 do. *Stonehouse*—St. Paul's Chapel, 1 plate. *Torquay*—Interior of Ball-room, 1 plate. *Tavistock*—Library, Ball-room, &c., 3 plates. *Cornwall*—County Lunatic Asylum, 8 plates. *Bristol*—Gaol, 5 plates.

Conceiving that every work ought in some measure to be judged by what it aims at, and by what is the author's professed aim, we shall here let Mr. Foulston explain himself, in order that more may not be exacted of him than he promises:—

> The author, in publishing this work, illustrating the buildings erected from his designs, makes no claim to originality, except as regards construction and adaptation. * *
>
> In exhibiting his designs, the author is aware they must be considered merely as models calculated for the atmosphere of a town remote from the metropolis, and, though spirited, proverbially poor. * *
>
> Many volumes of general plans and elevations have been published from time to time, giving some notion of *arrangement* and *proportion*, but affording none of that *practical information* which chiefly, of a professional student, constitutes the value of an architectural book. While, therefore, it has been the author's aim to obtain the attention of the amateur by his general elevations and perspective views, he has been still more desirous of attracting the notice of the young architect by his "details at large," as they are architecturally termed; and by thoroughly developing the internal mechanism of his more important buildings.

With these extracts from the plain and sensibly-written "Address" prefixed to the work, an address so different from the pompous, lumbering prefaces which a certain other party puts to his publications, we dismiss the work for the present, reserving our further remarks on it for our next number.

Hints to Mechanics on Self-education and Mutual Instruction. By TIMOTHY CLAXTON. London: Taylor and Walton. 1839.

Just in the same manner as in physical subjects we value the experience of practical men, so in moral and social questions we derive pleasure from seeing them treated by those who are "to the manner born." This is the gratification which must be communicated to every reader of the amusing book before us, which has all the ease and simplicity of De Foe, and the exemplary utility of Franklin. To the mechanic it offers at once an example and a pleasant companion in the pursuit of knowledge, and to the general reader it affords a deep insight into those labouring classes which are the sinews of the nation. This bearing of the work we must, however, leave to our literary brethren, and content ourselves with such practical extracts as may be of interest to our utilitarian readers.

The author, in his plain and easy style, while giving an account of his labours in Russia, thus mentions the columns of the church of St. Isaac, the greatest cathedral work of the present century:—

Some of their columns made of granite are very large and highly polished. I took the pains to measure one of the columns intended for a new church, and found it fifty-six feet long, and near seven feet diameter at the base. They were brought from Finland, and two of them were a load for a ship, one on each side of the masts, to balance each other. They were rolled from the deck to the vicinity of the intended building on timbers nine inches square, (placed but little distance apart,) which were completely crushed to splinters. The rolling was performed by two ropes; one end of each being made fast, some distance a-head, to stakes driven into the ground. They were passed under the column, up the back side, and over the top. The other end of each rope was wound round a separate capstan. Each capstan had four long levers, with from ten to twenty men at each lever. These columns were placed in a temporary building for polishing.

I also visited the foundry where the bases and capitals were made. They were of brass, of the Corinthian order, and highly polished and gilt. The square *plinth* for the bottom measured about nine feet on each side, and one foot thick. Several women and children were polishing these with pumice-stone. The *torus*, a round bead belonging to the base, was turning in the lathe, and the workman had a very strong tool for this purpose. A steam-engine, with a man to attend it, was employed entirely on the work. The capitals, with their leaves and volutes, had a very splendid appearance.

The following is but one feature of the great scale on which they do things in Russia. The whole empire, indeed, is a great poor-law union, which beats our Somerset House commissioners by a long way: the whole is carried on with such system, that it almost realizes the satirist's suggestion of boarded, lodged, clothed, and flogged by steam:—

The building in which I was engaged in putting up the gas-works, was for transacting the business of the Russian army. In this building were several departments, with a "general" at the head of each, some of whom employed above two hundred clerks. In this building I saw lithographic printing for the first time; copper-plate and letter-press printing were carried on here, and a very extensive establishment for the manufacture of mathematical instruments, all belonging to the government; also a drawing-school, consisting of about two hundred young officers.

The next extract exhibits another of their arrangements for removing great weights:—

In another building I noticed a model of the machine on which a large block of granite, weighing upwards of nine hundred tons, was removed several miles. Peter the Great is said to have stood on this rock, giving commands to his army, when he subdued the Fins. The Empress Catherine ordered it to be removed to the city for a foundation on which to place a bronze statue of that monarch on horseback. Many ineffectual attempts were made for its removal; but it was easily performed afterwards by introducing cannon-balls for rollers between bars of iron.

The three wood-cuts exhibit some ingenuity, and although there is little that is new about them, we thought that they might be of interest to some of our readers:—

Fig. 1.

Fig. 2.

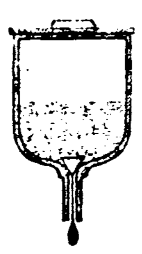

Fig. 3.

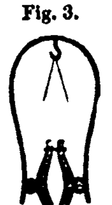

Figure 1 represents a contrivance for shutting doors. The power is applied in the same manner as in our modern printing presses. There is a pin at each end of the apparatus: one pin is fitted to and turns in a socket attached to the frame, and the other is fitted to a similar one on the door. In opening the door the pins are brought nearer together, and the weight in the centre is raised. The door is shut by this weight straightening the bars, and spreading the pins further apart. Some of these articles are made of iron, and are black; others are of brass, and kept bright; both kinds are extensively used. Figure 2 is a cistern for water, with a valve in the bottom, which is much used for washing the face and hands. By raising the valve the water is let down in small quantities, and, as it is used, passes off by means of a sink placed underneath. The advantages of this method are that persons do not wash in the same water with others, nor use it more than once themselves, which is not only more conducive to health, but makes less water necessary than washing in a common basin. These cisterns are made of various forms and sizes. Some of them have a dozen or more pipes, each furnished with a valve, so that many persons may wash at the same time; the large ones are made in a circular form, and placed in the middle of a room, but the small ones are hung against the wall. In figure 3 is represented a spring bow or arch. This is used with the horse-collar, for the horse that is placed in the shafts, as other horses do not have them. It was a long time before I could see any other use for this contrivance than to cause the horse to hold up his head, and to keep him from stumbling, by the bridle being hooked to the top of this arch. I was informed afterwards by an intelligent man, that the spring being connected with the collar prevented the shoulder of the animal from chafing, by continually easing the collar off, and suffering the air to pass between that and the shoulder of the horse.

This work will doubtless prove of considerable interest to our American readers; but the strict boundaries which limit the sphere of our labours, prevent us from entering into the work generally. It may, however, be read with gratification, for, as a piece of autobiography, it is as amusing as it is valuable, and fully reflects the character of its author, who is known and esteemed for his endeavours for the improvement of his working brethren.

Journal of the American Institute for Promoting Agriculture, Commerce, Manufactures, and the Arts. Vol. 3. New York. WAKEMAN, 1838.

THIS is a publication belonging to the New York Society of Arts and Manufactures, and is an excellent compilation of valuable materials from European and native sources. We find that our own work, among others, has been laid under contribution.

It contains, among other interesting subjects, the account of the last mechanics' fair at New York. Mechanics' fair is the term for an exhibition like that of the Conservatoire des Arts et Metiers at Paris, or rather like those of some of the continental provincial towns, and it is an omnium-gatherum of new inventions, old manufactures, confectionary, pictures, baby-linen, penmanship, perfumery, hobby-horses, and the fine arts. At the last fair there were above 1,500 contributors, and 160,000 persons paid down their admission shillings to the tune of about £2,000. The greater part of this money is re-issued in the shape of medals and premiums, and the institution, no doubt, stimulates enterprize equivalent to its popularity.

These fairs both at Boston and New York are strongly supported from political motives, being mainly upheld by the home manufacturing party. It is astonishing to see the strength with which protective duties and anti-free trade notions are maintained in the annual addresses; and it is very truly observed that partial free trade, without universal concurrence, is something like Governor Penn's peaceable constitution, laid at the mercy of neighbouring nations. Free trade is no favourite in the northern states, so that if our political economists are in the right, the progressing nation must be behind-hand for once.

We feel very happy to see ourselves in the far-west, for it is an additional proof to our readers, that we have been successful in endeavouring to fulfil our duties to them, while it imposes on ourselves the task of seeing that our labours may be such as to merit the extended circulation which our work has obtained both in the old world and the new.

Map and Sections of the Railways of Great Britain, with Tables of the Gradients. By GEORGE BRADSHAW. Manchester: Bradshaw, 1839.

This is a very careful compilation, on a large scale, from the best authorities, executed in a good style, and surpassing any publications of the same kind yet attempted. The railways for which acts of Parliament have been obtained are accurately delineated, and the accessories are executed with equal attention. The canals and roads are given in such a manner as to render it equally valuable for a general map as for its special object. By the side of the map are sections of all the railways, enabling the spectator to form an estimate of the gradients at a glance. The canals in the map have their levels marked upon them, and it would have been a considerable benefit if the same plan had been pursued as to the railways.

On the whole, it is a work which does credit to its compiler, and seems to be attended with few faults either of omission or commission. By some error of the colourist, the Oxford and Dudcot branch is represented as if it had obtained parliamentary sanction, and we observe that this and some other minor proposed lines, as the Harwich are inserted, while others in agitation, as the St. George's Harbour, Morecambe Bay, &c., are omitted. We suppose that the London Grand Junction is left out on account of the expiration of the act. We are glad to perceive that an announcement in the prospectus as to all the levels being reduced to that of low water at Liverpool is incorrect, although it would be advantageous if the datum were taken from the Trinity standard, as that of the longitude is from Greenwich.

In conclusion, we may award the meed of approbation to this work, as being one of great practical utility, and conferring high honour on its compiler. It is most appropriately dedicated, by permission, to James Walker, the President of the Institution of Civil Engineers; and thus, while it acquires a higher value with the public, pays an honourable tribute to the exertions of that gentleman.

LITERARY NOTICES.

The Monthly Chronicle, with an article on the Great Western Railway question, has been sent to us, but we have not thought it necessary to extract from it, as the matter seems only a dilatation of Mr. Wood's report, published by us in our present number. As to the argument pursued by the well-known author, relative to atmospheric resistance, he shows too much doubt himself of its feasibility by the intercalation of the phrase "in the present state of science," to render it necessary for us to refute it. Perhaps the author may do so himself; at any rate the present experiments are evidently incomplete, and it does not follow that a ratio of resistance existing at a certain period should continue uniform throughout. This resistance, as well as others, may be subject to the cyclar law of variation, and like the velocity of boats on canals become more favourable at a higher speed.

That valuable and cheap compilation, *Wyld's Monthly Index to the Times Newspaper*, has with the new year increased the sphere of its labours, and is enlarged to an *Index to the Metropolitan Morning Papers, Times, Chronicle, Herald, Post, and Advertiser*. It gives for the same price as before, 10,000 distinct references to 3,000 heads, and presents such a mass of figures, that were it not for the clearness of the arrangement, it would be sufficient to repulse the reader. The address contains some most interesting remarks, and the work itself is of that utility that no man of business should be without it.

Our attention has been called to a pamphlet entitled, *Hints on the adoption of the Broad Gauge on the Great Western Railway*, by Traffic; but as it is only a puff of a proposed line, repeating oft-refuted assertions, we do not think it necessary "to burnish the refined gold."

We have examined the last three parts of *Dr. Ure's Dictionary*, and we feel pleased to see that it still maintains its high character for utility. In the last number, which is the fifth, is an interesting table of chemical formulæ, and an excellent account of the manufacture of gas, which we should be tempted to extract, were we not assured that most of our readers have provided themselves with the original work, so that it would be like carrying coals to Newcastle. We see that the Doctor promises a new work on chemistry, which we have little doubt will be, like his other compilations, a valuable addition to the stock of science.

We shall refer to *Davy on Foundations* in our next Journal.

ORIGINAL PAPERS, COMMUNICATIONS, &c.

RALPH REDIVIVUS.—No. 18.

THE EXCISE OFFICE.

Most persons, I am inclined to suspect, employ certain current epithets and phrases, either without attaching any meaning at all to them, or else a very false one. One of the cant terms thus bandied about is *simplicity*; but when you ask what is meant by simplicity, you are stared at as being a most dunce-brained ignoramus, or an exceedingly disagreeable and impertinent bore. The result of all your inquiries and cross-questioning will be, that simplicity is simplicity, nothing more nor less, and that you must be a prodigious simpleton not to understand it. Perhaps, the better definition would be that it is a quality which everybody admires, or pretends to admire, which most people fancy they can see where it does exist, and which very few can perceive when it is actually before their eyes.

That it exists, for the most part, only in the imagination, or, perhaps, only upon the tongue, can hardly be denied, when we consider the sort of things which are praised for their simplicity, although more frequently than not, they are mongrel compounds most clumsily put together: for instance, a dull school-boy copy of a portico, (that is, of a few columns with an entablature and pediment—tied to a building where it is not only superfluous as far as utility is concerned, but worse than superfluous, a positive absurdity as regards consistency of style, or even mere artistical effect), shall be admired for its simplicity, although it ought rather to be reprobated as a vulgar affectation and absurdity, manifesting nothing so much as sheer obtuseness of taste, and utter sterility of ideas. On the other hand, that it cannot be perceived or estimated when actually placed before people's eyes can hardly be denied, when we consider how ill we appreciate an edifice that, for its dignified simplicity and unaffected nobleness of expression, has not its equal in the metropolis. I mean the Excise Office. Let any one, after looking at the tawdry insignificance of the columned façades in the Regent's-park, go and contemplate the unpretending grandeur of the edifice in Broad-street, and he cannot fail to be struck with the vast superiority of the latter, and with the imposing presence it makes. If such really be the case, it will be said, how happens it that its merits have been overlooked, and that no one ever refers to it as a piece of architecture? Is not that extraordinary? *Tout au contraire*; that it should be neglected is quite in the ordinary course of things. It is marked by no striking features, much less does it recommend itself to the vulgar eye, by any of those *prettinesses* which are almost sure to command vulgar applause. Its value lies in character and expression, and in its totality of effect, qualities which, it would seem, are altogether caviare to the million. Besides which it is not, like St. Bride's steeple, one of those things for which the good citizens are taught from their infancy to entertain traditional admiration. While it is too old to be stared at as a modern improvement it is not old enough to be gaped at as being of long standing and universal note. Above all, it has never, like some productions greatly inferior to it, had the good luck to have a current reputation given it, by any generally recognized critical authority.

Nevertheless, all honour be to James Gandon, for in what he has here achieved, he has shown the true feeling of a master. It is, indeed, almost the only thing in all London that really looks like a palace, or that is worthy to pass for one. That erected, in evil hour, by Nash, admits of no comparison with this edifice, for greatness of manner, and stateliness of appearance. There, every part has a squeezed-up, little, and finical look; and, notwithstanding that there is a good deal of embellishment, or what is intended as such, the building has not the slightest air of richness; neither does it offer anything that can properly be termed variety; but, contradictory as it may sound, is stamped by insufferable monotony, although it exhibits nothing whatever of unity.

It is absolutely refreshing to turn from Nash's architectural *Micromegas* to this work of Gandon's, where the eye reposes with prolonged satisfaction on the breadth and *grandiose* physiognomy of the *ensemble*; to which all the proportions very happily contribute. Considerable as is the extent of front, it is not so great as in any degree to counteract the expression of unusual loftiness, which may be said to be the predominating one; and what conduces not a little to it is that there are no horizontal members dividing the height, and cutting it up into a succession of distinct compartments from the ground to the summit. If we compare it in this respect with Inigo Jones's building at Whitehall, we can hardly help feeling the great superiority of Gandon's. There, we behold a diminutive basement, and two small orders without any crowning member to give importance to the summit of the edifice; here, a basement of unusual loftiness comprising two series of windows, and above it a principal and secondary floor surmounted by the cornice that crowns the entire mass. Without thereby losing any of the consequence it derives from height, the first-mentioned portion of the structure acquires more importance in the design from the variety thrown into it, owing to the modes of rusticating employed, that below being of a more masculine character than the other. Nor is variety the only merit arising from this combination, because, to my eye at least, the upper part of the basement thus forms an agreeable transition from the more massive substructure to the more finished superstructure. This duplication of the basement is, besides, excellently well-motived by the lofty arch, which is so effective a feature in the whole composition. Substitute an ordinary sized doorway for it—either in idea or upon paper, and it will instantly be evident how greatly all the rest would suffer by such alteration alone. Another circumstance that mainly contributes to the air of external grandeur and internal spaciousness which distinguishes this piece of architecture consists in the proportions between the solids and apertures. Even in some parts of Somerset-house, a certain *petitesse* prevails, owing to the windows being too numerous for the surface they occupy; besides which the intermixture of windows with dressings and others without them, upon the same floor produces a patchy and parsimonious appearance. Here, on the contrary, the apertures are admirably proportioned to the whole façade, are effective but not obtrusive features—and although far from petty in themselves—subservient to the larger spaces; whereas in the building by Jones before alluded to, the windows predominate too much, and cause the columns and pilasters to appear diminutive in comparison with them.

Honour be to James Gandon, an architect to whom Dublin, I should observe, is indebted for its finest structures, and the author of what is undoubtedly by far the finest specimen of simple unadorned grandeur in our own metropolis.

CANDIDUS' NOTE-BOOK.

(Second Series.)

[The First Series of these papers appeared in the "Architectural Magazine," which work being now terminated, the writer has consented to continue them in this journal, under the same title, as that will identify him at once—perhaps recommend him better than a fresh one, to those of his present readers who here meet with an old acquaintance.]

FASCICULUS I.

I. Within about the same time that was employed on the single church of St. Peter's at Rome, the northern metropolis, named after the same saint, has arisen from its foundation to its present magnitude and grandeur. Yes, not quite a century and half have elapsed since the site of St. Petersburg was a dreary morass, and ere that century and half will have been completed, will the St. Isaac's church, one of the most stupendous achievements of modern architecture, be finished. The works are now proceeding with great rapidity, and it is confidently anticipated that the whole will be completed by the year 1842; and whenever it is, it may perhaps challenge the world to produce its equal for external grandeur and for sumptuousness of material. The whole of the exterior will be of marble, granite, and bronze, and the dome will be gilt with ducat gold. The height of this dome is 340 Russian feet, or very nearly 400 English ones, consequently greatly exceeds that of St. Paul's, which difference, though inconsiderable in proportion to their actual size, gives prodigious increase of magnitude, just as every additional inch above six feet does to the stature of a man. The number of columns, each consisting of a single piece of highly-polished granite, is 104, of which those forming the porticos are nearly sixty feet high, and the remaining thirty-two, around the tower or tambour of the cupola, of somewhat less dimensions. Neither is it in the magnitude alone of some of these structures that the Russians surpass us, but also in the celerity with which they execute them. The Winter Palace at St. Petersburg was burnt down about the same time as our Royal Exchange; but while the ruins of the latter are but just cleared away, the former is by this time rebuilt!—at least, in the middle of last August the works had advanced so far that it was expected the Emperor would be able to hold his new-year's levee there, for no fewer than five thousand men (a great number of them soldiers) were employed on the edifice. Very possibly this energy may in some respects be censurable, inasmuch as hardly any time can have been allowed for duly maturing the plans; but it certainly offers a very striking contrast to the drowsy mode in which we proceed here at home. The British Museum creeps on at a most tedious snail-like pace; indeed, if it does not soon begin to mend its pace, it is hardly likely to be finished before they end of the present century.

II. To me it appears almost inexplicable, that among the swarms of tourists and travellers who return every season from abroad with the materials for a volume or couple of volumes in their note-books, there should never be an architectural one. Most assuredly it cannot be because an architect can now meet with nothing that has not been described again and again, since to go no farther than Paris and Versailles, they alone would furnish matter both of description and criticism hitherto quite untouched. Even the hackneyed route to Rome affords many ungleaned patches, there being scarcely an Italian building of the present century which has obtained any notice from travellers. It is true, Italy has produced comparatively little in the way of architecture of late years; nevertheless, much has been accomplished that is exceedingly well worthy of note. There is, for instance, Canova's Tempie di Passagno, or Church at Passagno; to say nothing of several beautiful edifices at Milan and elsewhere, by Cagnola, and others by Dordoni, Bianchi, Durelli, Di Secco, Peverelli, &c. But if Italy holds out little that is new, there are Munich, Berlin, St. Petersburg, and various other capitals, which are as yet quite untrodden ground to English architects—places where they might at any rate pick up some fresh ideas. Non-architectural writers and tourists, on the contrary, are apt to make exceedingly bad work of it, whenever they attempt to describe buildings or discuss their merits. It is, therefore, quite a god-send when we meet with such clever descriptive sketches as the "Critical View of the Architecture of New York," and the "Fragments of a Provincial Tour," in the concluding number of the "Architectural Magazine." The only fault in them is, that, although not short articles in themselves, they create a longing for very much more from the same pens. Mr. Humphries ought to extend his tour much further; and, as he is quite *au fait* with his pencil as well as with his pen, should give it to the public in an illustrated octavo volume. His intelligent descriptions and remarks would be most acceptable, particularly were the former to be somewhat more expanded.

III. Among much other information to be obtained from Mr. Humphries' "Provincial Tour," the following is not the least worth notice:—"Beyond the church (at Manchester) I found the old college, an interesting building, unrestored and unadulterated by modernization of any sort. It was founded by one Cheatam, a high-minded merchant like Gresham, who has thus conferred a lasting benefit upon his native town. It contains a good library, which is *public* in the true sense of the word; that is, any person may go at any time, and call for any book he requires, unannoyed by any irksome restriction whatever." Prodigious! What a simple, plain-dealing creature must that same Cheatam have been to have given a library to the public upon such easy terms, without so much as imposing *any irksome restriction whatever!* What grovelling, childish notions of munificence and public spirit the man must have had!—certainly widely different from those entertained by old Soane, who would far more worthily than the other have become the name of *Cheat'em.*

IV. The two great stumbling-blocks of art, or the Scylla and Charybdis on which it is generally wrecked, are pedantical, spiritless precision and exactness on the one hand, dull licentiousness and disregard not only of all authorities, but of all conditions of art, on the other. The great point is to know how to emancipate ourselves from the trammels of slavish imitation, without—I will not say running into wild, chimerical extravagances, but without destroying those qualities of the style aimed at, which confer upon it its chief charm and value.

V. It does not often happen that the "Gentleman's Magazine" ventures upon anything like honest critical remark in regard to any of the buildings it notices. The following strictures, therefore, in the volume for 1826, deserve to be here brought forward again, and to many will be entirely new. "Expensive and numerous," says E. J. C., "as are the public buildings in progress, though the names of Soane and Smirke may be quoted as the architects, and the thousands expended in their construction be adduced in their favour, are, I would ask, any one of them *grand?* On the contrary, do not the new buildings present one uniform air of meanness? The spacious wing added to the British Museum, with its unbroken brick wall, seems to have been built to compete in beauty with the King's Bench, or the Fleet. The new Post-office, like the new Mint, and the generality of Mr. Smirke's buildings, is as tame and spiritless as plain stone walls with dwelling-house windows, and a few columns stuck about them as apologies for porticos, can be. If the *ephemeral praise of periodicals* was sufficient to exalt the character of a building, it is but a few years since that all the newspapers and periodicals, from one end of the kingdom to the other, were filled with applauses on that huge and senseless pile the Custom-house." As to the new Mint, that has certainly not conduced at all to Smirke's fame. Indeed, it lies in a territory criticism never travels into; which, however, may be a rather fortunate circumstance for it than not, because the less it is known and spoken of, the less likely is it to be condemned.

CONSTRUCTION OF LIGHTHOUSES ON SANDS.

We now lay before our readers one of the most important experiments of the present day, which promises to give to the engineer a foundation as secure in the sea as he has hitherto enjoyed on the surface of the earth. The success of this attempt will give us resources to battle with an antagonist, before which all our mechanical strength has too often proved defective, while, to the maritime interests of the country it will afford new and further protection. We can appreciate the difficulty which Smeaton encountered in planting the Edystone on the firm rock; but we have now the means offered to us of security even upon the shifting sand.

At page 22 of our last volume, we were, through the kindness of Mr. Elmes, enabled to give a description of "Mitchell's Patent Screw Moorings," but we did not then anticipate the application which they have since received. It having been brought under the notice of the Corporation of the Trinity House that this instrument might be advantageously applied in establishing lighthouses on sands, their attention was immediately given to the subject, and accordingly directed an experiment to be made to ascertain its practicability, under the superintendance of their engineer, Mr. James Walker.

The spot selected is on the verge of the Maplin sand, lying at the mouth of the Thames, about twenty miles below the Nore, forming the northern side of the Swin, or King's Channel, which, on account of its depth, is much frequented by large ships, as also by colliers and other vessels from the North Sea, and where a floating light is now maintained. This spot is a shifting sand, and is dry at low water spring-tides. The plan is to erect a fixed lighthouse of timber framing, with a lantern, and residence for the attendants. For this purpose, in August last, operations were commenced to form the base of an octagon, 40 feet diameter, with Mitchell's mooring screws, one of which was fixed at each angle, and another in the centre; each of these are 4 feet 6 inches diameter, attached to a shaft of wrought iron about 25 feet long, and 5 inches diameter, and, consequently, presenting an immense horizontal resisting surface. For the purpose, a stage for fixing the screws, a raft of timber, 30 feet square, was floated over the spot, with a capstan in the centre, which was made to fit on the top of the iron shaft, and firmly keyed to it; a power of about 30 men was employed for driving the screws; their united labours were continued until the whole force of the 30 men could scarcely turn the capstan: the shafts were left standing about 5 feet above the surface of the sands. The fixing of the nine screws, including the setting out the foundation and adjusting the raft, which had to be replaced every tide, did not occupy more than nine or ten days.

This is the portion of the work hitherto effected, and its continuation will be proceeded in when the proper season comes in the ensuing spring. Upon this foundation the superstructure of timber is to be constructed, consisting of a principal post, strongly braced and secured, with angle-posts made to converge until they form a diameter of about 16 feet at the top, giving the superstructure the appearance of the frustrum of an octangular pyramid, the feet of the angular posts and braces are well secured and keyed down to the tops of the iron shafts, and the whole is connected at top and bottom with strong horizontal ties of wood and iron. The entire height of the superstructure will be 30 feet above the top of the iron shafts; up to a point about 12 feet above high-water mark spring tides the work will be open; the part above will be enclosed as a residence for the attendants; in the centre and above this will be erected a room or lantern of about 10 feet diameter, from which the lights are to be exhibited.

The interval that has elapsed since the screws were fixed has fully proved the security of them, which, although driven into sand, seem as if fixed into clay, and in this state they have remained since the summer. The whole process confers the greatest credit both on the engineers and Mr. Mitchell, the patentee of the screws who superintended the work, (assisted by his son) and we feel happy to hear that his ingenious invention daily obtains a greater extension.

The importance of this experiment certainly called for a trial, and it was with due liberality that the Trinity Board sanctioned the expense. To them it involves the question of a better security of the light, and a less expense in its maintenance, both objects justifying the experiment, and counter-balancing the expense of prime cost in such construction. The insecurity of floating lights has been too manifestly productive of disastrous consequences not to call for a remedy, and it will be fortunate if by this means it be obtained. Within the last month the Nore light was blown from her mooring; and the breaking away of the North-west Light of the Mersey is supposed to have led to the lamentable shipwrecks at Liverpool.

We can perceive only one objection which can be started, and that is rather to be determined by experience than conjecture, that is how far the edifice is liable to be washed away by storms as one of the Edystone buildings was; but this, in our opinion, will be mainly provided against by the unity of construction and the breadth of base well secured to the shafts by the screws.

The progress of this work will naturally be watched with interest, for it is one which in its influence is not limited to this individual case. It is of much more importance than chain piers, as it will enable us to obtain a foundation in positions where they cannot at present be used. It must be remembered that the screw can be employed where the pile is of no avail, and that it possesses a much stronger hold, and has greater durability.

We shall thus, therefore, be able to construct piers and breakwaters in localities inaccessible, and be enabled to render important service to the interests or commerce. We think, too, that the screw itself would be of great utility in securing the end chains of suspension-bridges, as its powers of resistance can be extended to any necessary degree by an increase in size. The greater employment of the screws, which would arise from their successful application, will have a further beneficial effect in enabling the patentee to supply them at a diminished expense, which, under their present limited sale, is necessarily high.

The carpenters' work of the superstructure is about to be contracted for, which is intended to be erected and put together at the Wharf at Blackwall to save time of fitting, &c., at the spot.

In order for the better understanding of our description of the mooring screws at page 22 in our last volume, we have obtained of Mr. Weale the use of the wood engravings illustrating his valuable publication, the "Public Works of Great Britain." They will exhibit, in a much clearer light, the construction of the moorings. The screws described above for the foundation of the lighthouse, differ in some respects from these engravings; instead of being furnished with a chain and shackle, they have a wrought iron shaft connected to the screw as before described.

Fig. 3. Fig. 2.

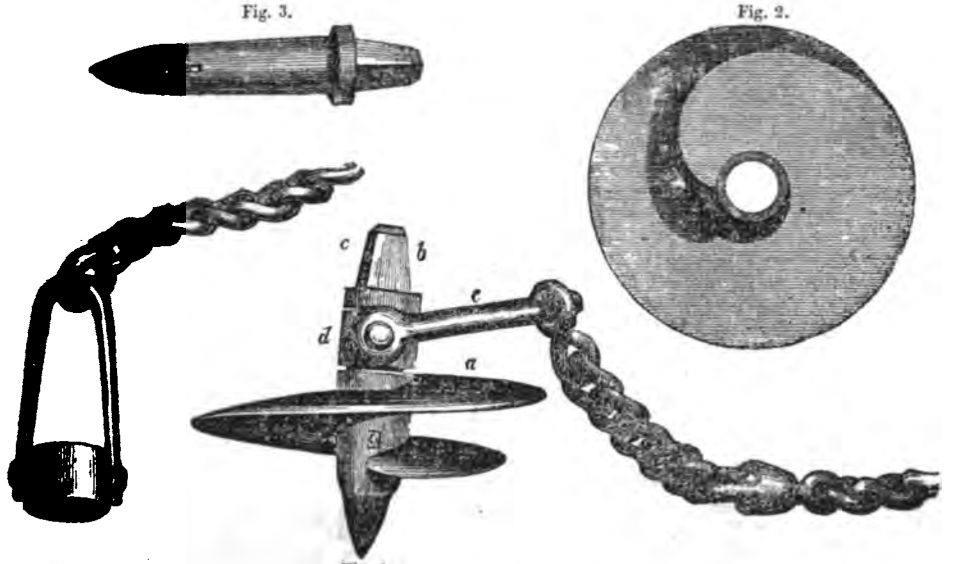

Fig. 4. Fig. 1.

Figure 1 shows the screw mooring as prepared for use. *a* is a spiral or screw flange of about one turn and a half, having a hollow cylindrical centre, as shown in *figure* 2, and of cast-iron in one piece; *b* is a wrought-iron spindle, which passes through the cylindrical socket of the screw flange, somewhat tapering in form, as shown in *figure* 3, and when driven up tight, is fixed thereto by a forelock, which passes through both; it is formed with a square head, *c*, to receive the key for screwing it into the ground; *d* is a collar of wrought iron, the front of which is shown in *figure* 4, fitted so as to turn freely on the upper part of the shaft of the spindle below the collar. *Figure* 2 shows the upper surface of the spiral flange; *figure* 3, the spindle; and *figure* 4, the collar and shackle. The shackle is fixed to the spindle by means of the loose collar, in order to prevent the dragging round, and the consequent fouling of the chain, whilst the spindle is being turned in or out of the ground.

HARLAXTON.

When we stated, in our review of "Dr. Dibdin's Tour," that Mr. Gregory's splendid new mansion at Harlaxton, near Grantham, was begun by Mr. Blore, we had fallen into a mistake, which we now correct. The architect originally employed, when the building was commenced in 1832, was Mr. Salvin; and although the execution of the work has since been committed to other hands, his designs have been adhered to. Mr. Blore was called in, but only to be consulted; and Mr. Burn, who was afterwards engaged to complete the edifice, had only to erect what remained to be done, in strict conformity with that half or portion which had been built by Mr. Salvin; consequently, to the last-mentioned gentleman belongs whatever reputation this mansion may acquire as a piece of architecture; and, notwithstanding that it is in a style to which, as a style, we are by no means partial, we are free to confess that it is infinitely more to our taste than almost any other specimen of it we are acquainted with.

The principal or entrance front—that facing the north—is, indeed, a most picturesque and masterly composition, presenting a refined ideal of the style, where all its best qualities are brought out and blended together, and where features, which, taken by themselves, have no pretensions to grandeur or elegance, are made to contribute towards the richness and stateliness of the *ensemble*. The true feeling of an artist manifests itself throughout every part of this façade. It is so perfect a picture that all our prejudices against the style itself not only are silenced before it, but serve to enhance our admiration, when, contrary to all our preconceived ideas, we behold what may be produced out of it when treated with geniality of taste. We shrink, however, from the task of attempting to convey, by mere words, any intelligible idea of so complete and varied a composition as this front. In description, the whole would appear little better than profusion and confusion; whereas, in the design itself, notwithstanding the great number and diversity of its features, the whole is perspicuous and harmonious. The centre compartment, flanked by two turrets, and crowned by a larger one of highly decorative character, presents itself as almost one entire mass of ornament, yet without seeming in any degree crowded; there is nothing superfluous, because there is nothing that does not evidently conduce to the character here aimed at. The other principal front, which is not quite so lofty, being raised on a terrace occupying the depth of the ground-floor on the entrance side, is that facing the west; and here the lower part, or that on the level of the terrace, is occupied through the whole extent from north to south by the gallery, that is, by what Dr. Dibdin describes as the drawing-room. This gallery measures 97 feet by 25, exclusive of the northern oriel, besides which there are two bays and a lobby communicating with the terrace on the west side. On the other side of the gallery are two fire-places, one facing each of the bays just mentioned, and between them a door leading into an ante-room, (25 feet square,) beyond which is the dining-room, 40 feet by 25, exclusive of an additional space 37 feet by 10, and further extended by oriels, and recesses with windows, which latter are in the turrets at the angles of the centre compartment of the north front. Behind this dining-room is a spacious hall or reception-room (78 feet by 27, and two stories in height), whose lofty oriel and other windows form such conspicuous and characteristic features in the elevation of the south front. The principal drawing-room (36.6 × 25) is at the west angle of this front, where it forms a projecting wing, between the great hall and the gallery, with the principal staircase at the rear of it. This latter communicates with the ante-room between the gallery and dining-room; thus affording a line of upwards of a hundred feet, from the fire-place in the ante-room to the south bay of the drawing-room.

IRISH RAILWAY COMMISSION.

(*Continued from page* 15.)

The Irish Railway Commissioners speak of the port of Havre, in France, at page 66, thus :—

"We know that it is a question of doubt still pending whether Havre, or some other place in France, or a port of the British Empire, shall henceforth become one of general resort for the business to America for a great part of the continent of Europe, and a favourable result for our own country can only be obtained by the establishment of facilities manifestly superior to those of Havre or other French ports."

In looking over the very few pages which the Railway Commissioners' Report contains regarding the best harbour on the western shores of Ireland, which should be selected as the port to communicate with America, and the very few and limited observations they have given as to the success of an intercourse by steam with the new continent. The total want of any kind of exposition on the very extended range that steam navigation across the Atlantic will naturally assume with all the large commercial sea ports situated on the western shores of Europe, with those on the eastern coast of America. The extremely objectionable system of railways, which the Royal Commissioners have laid down, to connect the three largest cities in Ireland, viz., Dublin, Limerick, and Cork, shows that the Commissioners have not been able to elucidate in a full, clear, and satisfactory manner, even any one of those very interesting subjects, although "My Lords have full evidence from the character of the gentlemen appointed to form the commission, that their labours will be conducted in a satisfactory manner."

The position assumed by the Commissioners as to a general port or ports, either on the south or west coast of Ireland, to communicate with America by steam, and to be a general port for a considerable part of Europe, is not shown to be based upon any reasonable grounds for such an assumption; and in merely assuming that this will be so it has been recommended by them not only to connect Dublin, Limerick, and Cork, by railways, amounting to 316 miles, but also to make a new railway through Wales, not less than 140 miles long, and which will cost more than ten million sterling.

The Commissioners' report strongly recommends that the Government should make no less than 456 miles of railway, or nearly double the length from London to Liverpool* for the principal object of endeavouring to make Cork, as they state, the general point or port in Europe for communicating by steam with America. I am thoroughly convinced that when the British parliament examines those magnificent projects of the Royal Irish Commissioners that it ought not to advance one single penny towards the execution of a line of railway through Wales of 140 miles in length, or to the making of 316 miles of railway through the southern part of Ireland for the mere hazardous chance that one of the southern ports of Ireland might become the port of general communication by steam between Europe and America. Does not reason announce that such has been the success of steaming from America into Bristol and Liverpool, that no western or southern harbour in Ireland is ever likely to become, in the present condition of commerce, the general port to communicate with America by steam, or for any portion of the continent, Great Britain, or even Ireland herself.

From the triumphant success which has attended the voyages of the Great Western and other steamers in navigating across the Atlantic between Europe and America, it must be quite clear to every person at all acquainted with the progress of steam navigation, that all the large British ports which may have business with the states of America, to any extent, such as Bristol, Liverpool, Glasgow, London, &c., will all have their own American steamers in the course of a short period. This is fully established by the present condition of steam navigation between London, Cork, Belfast, Dundee, Inverness, Hamburgh, St. Petersburgh, Portugal, Malta, Egypt, &c., &c.

Let any one acquainted with the rapid progress of maritime steam navigation during the last 25 years, read the extract at the head of this article and say if it does not lead to conclusions and speculations of the most absurd and ridiculous kind. To state that people in America returning to England, France, Belgium, Germany, &c., would be desirous to arrive at an Irish port in preference to an English or a French one carries its own refutation. I can venture to tell the Government of this country, the Royal Irish Commission, as well as those who are concocting this very extraordinary job, that France will have her own steam vessels for American intercourse as well as Britain. France is too powerful, too great, too maritime, too commercial, and too ambitious, not to avail herself of all those advantages which steam intercourse with America will confer and offers to other nations. The noble harbour of Brest lies nearly under the same longitude as Falmouth, and is much more westerly than Bristol, Liverpool, or indeed any port in England except the first, and a steamer sailing from Brest only requires 12 tons of additional coal for a voyage to America to reach the longitude of the most westerly harbour in Ireland, while on the other hand the parallel of Brest is a much better climate than that of Ireland to navigate from for America; besides the port of Brest would be the best for Central Europe to communicate by steam with America, and possess many advantages in this respect over any of the southern or western ports or harbours in Ireland. Even the ports of Havre and Bordeaux will yet have steamers plying regularly to America.

Looking at the immense revolution which the application of the steam engine to navigation has so successfully achieved in all the seas of Europe and North America, looking again at St. George's Channel and the Irish Sea leading from the Atlantic to the port of Liverpool; to the Bristol Channel running from the main ocean to the port of Bristol; to the English Channel reaching up to near the port of London

* The expense of making the Liverpool, Birmingham, and London Railway (about 210 miles long), has been stated at ten millions sterling.

on the shores of the German ocean; to the Northern Channel and the Estuary of the Clyde stretching up to Glasgow. Are not these communications extending from the Atlantic Ocean to the principal ports of Great Britain admirable channels, and quite sufficient for all kinds of steamers to navigate to these respective ports. Thus has nature laid open the whole of the harbours and commercial ports in the Empire to all the advantages of steam navigation with the states of the new world; and be it further observed that these magnificent sea channels have cost the nation nothing and never will require any kind of repair. On the other hand, looking to the land, is there not a railway already made and extending from Liverpool to London? and from which harbour or ports steamers are plying to all the principal ports of Holland, Belgium, and the north of France, Hamburgh, and even to St. Petersburgh. Again a railway communication exists between England and Hull, facing Hamburgh on the continent, and laying open the whole of the northern countries bordering the Baltic sea; and is there not a railway in full progress of execution which will connect Bristol and London called the Great Western? I ask are not these channels, harbours, and railways, quite sufficient to afford all reasonable facilities and accommodation to general intercourse with the American continent by steam, without embarking the government in the great expense of making 140 miles of railway through the mountains of Wales; and 316 miles of railway through the southern districts of Ireland, which would incur an expenditure of ten millions sterling, on a mere chance or probability that Cork might become the "*general resort for the business to America for a great part of the continent of Europe.*" The endeavour to make Cork a point of general resort for the business to America is made to appear the ostensible reason why government should make so many hundred miles of railway through Wales and the south of Ireland. It is under this mantle of a western port for the accommodation, as it were, to the intercourse of a great part of the continent of Europe is concealed one of the most extraordinary projects that has ever been attempted to be carried into execution within the realms of this empire, but it is to be hoped that the good sense of the British parliament will at once put a stop to any further proceedings as regards the recommendations of the Railway Commissioners. W.

LONDON AND WESTMINSTER BANK.

ARCHITECTS.—CHARLES COCKERELL ESQ. R.A., F.S.A.; AND WILLIAM TITE, ESQ. F.R.S.

The new building for the city establishment of the London and Westminster Bank, which has just been completed, is situated on the north side of Lothbury, immediately opposite to the north-east angle of the Bank of England. The whole structure occupies a site of nearly 80 feet in frontage, and 90 in depth. The façade consists of one general plane or face, broken only by an advancing pier at each end. It has seven apertures in the length, and three tiers of them in the height; the two lower tiers, comprehending the openings on the ground and one-pair floors, are included in one architectural story, or order, if such it may be called, the upper tier, which consists of the windows of the two-pair floor, being contained in an attic story. The whole of the front is of Portland stone, with the exception of the plinth, which is from the Bramleyfall quarries. The entrance vestibule or avenue has, on each side, a line of four plain Doric columns, with appropriate accessories. From this vestibule access is gained on the right to the country bank, the principal staircase, and some official apartments; and directly in front, to the principal or town bank. The latter apartment is by far the most considerable in the building. Its general form is a square of about 37 feet, whose height is that of the entire building, and it is extended by lateral recesses, east and west, to a portion of this height. These additions or aisles are divided from the centre, on each side, by an arcade of three arches, springing from Doric columns, with cornices. The surrounding walls are channelled in rustic courses to the height of this order. The recesses are sufficiently lofty to allow of the introduction of a gallery on each side, finished in front by a balustrade, abutting against the columns at such a height that the capping of the balustrade ranges with the abaci of the columns. Above this, the arches of the arcades run across over the aisles, and are intersected by a contrary vaulting, producing a system of groins as ceilings to the galleries; they are also advanced over the main body of the building, and treated as a series of half groins, so as to afford support to an upper gallery, which passes quite round the principal square. The verge of this upper gallery is guarded by a barrier, consisting of a double horizontal rail, sustained at intervals by ornaments of a scroll foliage. Over this gallery the lines of the cubical form below are continued through, and gathered up by means of pendentives in a domed figure, exhibiting nearly a hemisphere cut off by planes raised upon thides of a square inscribed within its circumference. The top of this dome is pierced by a large circular opening for a skylight, the margin of which is covered, and additionally ornamented with mouldings and lions' masks. Light is also obtained by triple windows, occupying the flat semicircular spaces left by the pendentives of the dome, on the three sides which are exposed to the view of a person entering; these windows are filled with glass in geometrical compartments, alternately ground and polished. Smaller semicircular windows are introduced likewise in the three arches on the north side, which form a continuation to those of the lateral arcades. Of the remaining apartments, the principal is the boarding-room, occupying a frontage of four windows on the one-pair story. On the same story are various apartments for the business purposes of the establishment. The two-pair story, and another above it, the frontage of which last is concealed behind the balustrade of the attic, are appropriated to the use of the resident manager. Ample accommodation for cellarage, strong-rooms, porters' apartments, &c., is provided in the basement story, which is fire-proof. The time occupied in the completion of this building has been about 18 months.

ASPECTS AND PROSPECTS.

The following judicious remarks relative to the choice of aspect for a house, we have extracted from the valuable work, entitled "Fragments, by the late H. and J. A. Repton." They are given in the form of a report concerning the situation for Walwood House, Laytonstone, Essex:—

Nothing is more common, than for those who intend to build, to consult many advisers, and to collect different plans from which they suppose it possible to make one perfect whole; but they might as well expect to make an epic poem, by selecting detached verses from the works of different poets. Others take a plan, and fancy it may be adapted to any situation; but, in reality, the plan must be made not only to fit the spot, it ought actually to be made upon the spot, that every door and window may be adapted to the aspects and prospects of the situation.

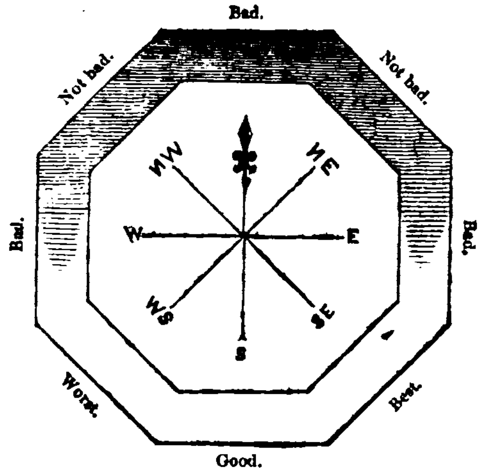
It was a remark of my venerable friend, Mr. Carr of York, after fourscore years' experience as an architect, that "to build a house we had only to provide all that was wanted, and no more, then to place the best rooms to the best aspects and the best views." Simple as this apothegm may appear, it contains more truth in theory, and more difficulty in practice, than all the rules which have ever been laid down in books by architects, or the remarks of all the admirers of rural scenery with whom I have conversed. The former never think of aspects, and the latter think of nothing but prospects. I will, therefore, beg leave to enlarge on these two subjects.

I consider the aspect of infinitely more consequence to the comfort and enjoyment of the inhabitant, than any prospect whatever; and every common observer must be convinced, that in this climate a southern aspect is most desirable; but few are aware of the total difference in the effect of turning the front of the house a few points to the east or to the west of the south; because, although the south-east is the best, yet the south-west is the worst of all possible aspects; for this reason—viz., all blustering winds and driving rains come from the south-west, and consequently the windows are so covered with wet, as to render the landscape hardly visible. My intention was originally drawn to this subject by travelling so much in post carriages, and often remarking the difference betwixt the window to the south-west and that to the south-east, during a shower of rain, or immediately after; when the sun shining on the drops causes an unpleasant glitter, obstructing the prospect, while the view towards the south-east remains perfectly visible.

At Organ Hall, in Hertfordshire, the living room was towards the south-west, and during a heavy storm of wind and rain we accidentally went into the butler's pantry, which looked towards the south-east, where we found the storm abated, and the view from the windows perfectly clear and free from wet; but on returning into the other room, the storm appeared as violent as ever, and the windows were entirely covered with drops, which obstructed all view.

On considering the prevalence of south-west winds, it was determined to reverse the aspects of the house by changing the uses of the room, making a very comfortable house of one which, from its aspect only, was before hardly habitable; since no window, nor hardly any brick walls, will keep out the wet, where a front is exposed to the south-west; for this reason, it has been found necessary in many places, as at Brighton, &c., to cover the walls with slates, or pendent tiles, and to use double sashes to the windows so situated.

If we had only one front, or one aspect to consider, our difficulty would soon vanish; but the prevailing partiality for variety of prospect seems to require that in every direction the views should be retained; and as the opposite walls of the house must be parallel, and the corners at right angles, we must consider the effect on each of the four sides thus:—



First, the aspect due north is apt to be gloomy, because no sun shine ever cheers a room so placed.

Secondly, the aspect due east is not much better, because there the sun only shines while we are in bed.

Thirdly, the aspect due west is intolerable, from the excess of sun dazzling the eye through the greatest part of the day.

From hence we may conclude that a square house, placed with its fronts duly opposite to the cardinal points, will have one good and three bad aspects.

Let us now consider the effect of turning the principal front towards the south-east, then the opposite front will be to the north-west; an aspect far better than either due north or due west; because some sunshine may be preserved, when its beams are less potent than in the west, and the scene will be illuminated by those catching lights so much studied by painters; especially where, as in the present instance, the landscape consists of large masses of forest trees, and thickets richly hanging down the side of an opposite hill. An aspect open to the north-east would be objectionable during the cold winds of spring; but in this instance it is effectually sheltered by an impervious screen of trees and large hollies, not drawn across the landscape, but perspectively receding in a deep bay, and forming an admirable defence against the north-east winds: while the richness and variety of this amphitheatre of evergreens will render the prospect as perfect as the aspect. This warmly sheltered corner will invite the cattle from every other part of the grounds, to enliven the home view near the windows.

It now remains only to mention the side towards the south-west; and having stated the objection to this aspect, we may consider it fortunate that the prospect in this direction is such as requires to be hid rather than displayed; and consequently the detached offices and plantations, to connect the gardens with the house, will defend the latter from the driving storms of the south-west, and give that sheltered and shady connexion betwixt the house, offices, and gardens, which constitute one of the most delightful *agrémens* of a country residence.

While speaking of the three different aspects, I have slightly adverted to their respective views or landscapes, but I will speak further on that towards the south-east, to which all the others may be considered as subordinate, although not sacrificed.

It is very common for admirers of landscape or natural scenery to overlook the difference betwixt a tree and a pole, or betwixt a grove of old trees and a plantation of young ones. We fancy that time will reconcile the difference; but, alas! we grow old as fast as the trees, and while we dot and clump a few starving saplings on an open lawn, we indulge hopes of seeing trees, when in fact we only live to see the clumsy fences by which for many years they must be protected. Happy, therefore, is that proprietor of the soil who becomes possessed of large trees already growing on the land he purchases, since no price can buy the effect of years, or create a full-grown wood; and without that we may possess a garden, or a shrubbery, but not a landscape. This consideration alone is sufficient to attach us to the vicinity of that venerable avenue, which it would be a sort of sacrilege to desert, and whose age and beauty will give an immediate degree of importance to the house, which could never be expected in any more open part of the estate.

The view towards the south-east will consist of a glade into the forest, where distant woods of Wanstead are seen betwixt the stems of large trees in the foreground, producing a purple tone of colouring so much studied by painters and admirers of picturesque effect. To this may be added the cheerful moving scene of a public road, not too near to be offensive; for however some may affect to prize the solitude and seclusion of a forest, shut out from all the busy haunts of men, yet within six miles of the capital few places can boast such privacy as Wallwood House commands within its forty acres, surrounded by a forest. Who then would regret to see occasionally, and at a proper distance, the enlivening mixture of man with animal life, and vegetation in its most interesting forms?

From its situation within so few miles of the metropolis, this place ought to combine all the pleasures of the country with the conveniences of a town residence.

REMARKS ON THE REPORTS OF THE GREAT WESTERN RAILWAY.

BY AN OLD ENGINEER.

Sir,—The report of Mr. Wood to the directors of the Great Western Railway, upon the principle of construction adopted by Mr. Brunel, its advantages and disadvantages, &c., and the contrasted results obtained by experiment upon other lines, having largely engaged the attention of the public for some days past, and as I do not coincide in opinion with Mr. Wood and Dr. Lardner, as to the mode in which some of the experiments were conducted, and the inferences deduced from them, you will perhaps oblige me by laying my strictures upon the report in question before your readers.

Before entering upon the subject, I cannot refrain expressing my admiration of the honourable and conscientious feelings evinced by Mr. Wood at the very threshold of the enquiry, that he was determined to constitute himself the mere chronicler of experiment, and in the spirit of a real philosopher, to go no farther than justified by its evidence. This temper contrasts beautifully, with the reckless, empty, report of Mr. Hawkshaw; and I am happy to record my respect in favour of Mr. Wood here, in the hope that his distinguished conduct may have its due influence with my professional brethren, to induce them more frequently, in like cases, to do likewise.

The experiments made to ascertain the tractive power and performance of the engines, and the tabulated arrangement by which the results are exhibited, meet my fullest concurrence; but I object to the statement "that the average weight of coke required to convert a cubic foot of water into steam, is not greater than what is required by the best constructed stationary engines, and less than Mr. Watt's standard, viz., 8 lbs. of coal to each cubic foot of water." Mr. Watt found that, to produce equal heat, coke is to coals, as 0.375 to 1, so that 8 lbs. of coke is equal to 30 lbs. of coal; thus, the locomotive in question consumes, comparatively, nearly four times as much as a fixed condensing engine.

The experiments to which I would particularly direct your attention are those made upon the inclined planes, with the view of ascertaining the atmospheric resistance, and the experiment was only varied in two ways, viz., by impelling a train of empty carriages down the plane, and then the same carriages loaded, and noting at what point the speed became uniform. The manner of conducting the experiment I consider by no means the best, and the results deduced from it exceeding fallacious. The first thing I should have done, would have been, to ascertain the velocity which the plane, or angle of inclination, was capable of generating; and I should have done this, by a skeleton carriage, alternately empty and loaded, exposing the least possible frontage or surface to the wind; the result would then have shown a certain point at which the velocity would not increase, a point at which gravity was counteracted by friction, &c.; this ascertained, then, the carriages, loaded and unloaded, might have been subjected to a like experiment, and the difference of the two velocities would have been then justly due to the enlarged frontal area. But even this method, if the subject sought had been merely the determination of the resistance due to the atmosphere, is not that which is most conclusive, if the frontal area alone be considered; for, had a surface like a kite been exposed against the wind, and the string connected with a spring balance or weighing-machine, the resistance of the surface at varying velocities, could then have been read off by the weights indicated upon the limb of the instrument. This would have been the true way of determining the matter, and would have been best made upon a level, and in an open country; but in whatever way the experiment had been made, it ought to have been when the wind was still, because, driving against the wind and with it are very different matters, and in the experiments, this circumstance ought to have been noted.

A body freely descending an inclined plane of 1 in 96, will be 96 times as long descending, as a body falling through the vertical height of the plane, and making no deduction for friction, when it reaches the bottom of the plane, its velocity would be the same as that attained by the falling body; now a body falls freely through 96 feet in two seconds and a half, at the end of two seconds and a half it will have acquired a velocity of 80 feet; but this velocity along the inclined plane will have been acquired when the body has reached the foot of the plane; but in practice the resistance from friction will be such as to reduce the velocity uniformly to a point somewhere about the mean, or half, which is proved by the experiment, and the addition of weight can produce no effect further than to increase the momentum of the body by so much as the weight is increased, but the velocity itself will be scarcely affected by the change, for the same reason as a cannon shot or a bullet, if let fall from the top of the Monument at the same moment, will both reach the ground at the same time; that this view of the case is correct, is proved by the experiment down the Madeley plane, on the Grand Junction Railway; here, as in the former case, the carriages being propelled down the inclined plane at a velocity of 30 miles per hour, (it is only a fair experiment to presume the starting velocity in both cases the same) and the carriages attained an uniform velocity of 30 feet per second, or 21 miles per hour, so that they were retarded until they were brought to the velocity the inclination itself was capable of generating without friction.

Mr. Wood says, "The force exerted by 15·6 tons down an inclination of 1 in 96 is equivalent to 364 lbs., and as this was the weight of the train in the first experiments, it follows that such a coach train, moving at 31 miles an hour, suffers a resistance of that amount, which includes both friction and atmospheric resistance," or, what is the same thing, that 364 lbs. represents the tractive force necessary to propel such a train, at the rate of 31 miles an hour, upon a level, including both friction and atmospheric resistance;" 364 lbs. raised 45 ft. per second is equal to the power of a 30-horse engine, and to produce the same results on a level, as shown by the experiments, requires a locomotive, evaporating 197·7 cubic feet of water per hour, or, in other words, an engine of 197·7 horse-power. This fact proves, that the power of a locomotive to produce a high speed is destroyed, or is most disadvantageously applied, and shows most conclusively that the great loss of power is not to be accounted for by the atmospheric resistance, as proposed.

As regards the observations respecting deflection, no notice seems to have been taken of the comparative bearing surfaces of the stone blocks, sleepers, &c. A stone sleeper is usually 4 ft. surface; placed at 3 ft. asunder will be 8 ft. bearing surface for the two rails, or a yard in length. A transverse wooden sleeper is scarcely ever more than 10 inches wide; if 6 ft. long, and 3 ft. asunder, the bearing surface will be only 5 feet. A longitudinal timber is seldom wider than 13 inches, giving 6½ ft. surface; this view of the case at once accounts for the superior solidity of the stone sleepers, for in fact the question of solidity must always be brought down to a question of surface, and that railway will be the most solid, other things being equal, the rails of which have the widest base; the mode, as admitted by Mr. Wood, of fixing the rails to the timbers is beyond all comparison safer than fixing them in chairs. A chair is seldom wider than 4 inches, and an inch and a quarter thick at the point of least section; then supposing them placed 3 ft. asunder, 1¼ inch will be distributed over a space of 3 ft., or a section of little more than one-eighth thick of cast iron, is placed to bear all the concussion of the engines and train, whereas, as in the case of Mr. Brunel's rail, every section of it is held down by a section of half an inch thick of wrought iron, and the leverage of the rail reduced fully one-half less than upon the London and Birmingham Railway.

However additional smoothness of motion may be attained by the removal of the piles and transoms, unless additional bearing surface be supplied, or the line perpetually packed, the levels will be lost by the sinking of the timber, for it is quite absurd to expect that any degree of consolidation can take place in a yielding and inelastic soil. In my opinion, the only proper method to be adopted is, to place the cross transoms closer together, and form a sort of flooring under the longitudinal timbers, thus throwing the load upon a wider surface, and this would be equally desirable if the weight and stiffness of the rail is increased.

Mr. Wood, in his enumeration of the conditions to be taken into account to form a perfect carriage, has omitted to note the perfect parallelism of the axles, a condition of more importance than any other, for if this be correct, the carriage is certain to run well.

The machine described to have been used to note the various vibrations, in my judgment must have been very ill adapted for the purpose; it must have been too mercurial, too sensible; had a heavy pendulum been employed instead, it would have given far more satisfactory results.

There is no doubt that the proper mode to link carriages, so that there shall be no concussion, is by an inflexible link between each carriage. Mr. Booth's patent draw-screws produces a good effect, but the simple inflexible link as adopted by Mr. W. J. Curtis, on the Greenwich Railway, is much more simple and very much better.

The 7 feet guage, which has been so much reviled, is most unquestionably the only gauge to carry out the plan which has been recommended by every person who has studied safety in railway travelling, and by no one more so than Mr. Brunel himself, to place the carriage within the wheels. By doing this, and allowing only one inch clearance, a width of 6 ft. 6 in. is obtained, and lowering the carriage to within 6 inches of the rail, a vertical height of 7 feet is procured, giving an area 45 ft. 6 in.; so that the Great Western carriages will be to the London and Birmingham as 45 ft. 6 in. to 53 ft. and it is impossible, with the London and Birmingham carriages, to make a similar improvement, without making them 8 or 12 inches wider.

One great advantage results to the public from the investigation which has taken place into the merits of this railway, proving the very defective condition of the system of railways generally, rendering it the imperative duty of railway companies to avail themselves of the suggestions and improvements of others, besides their own people. If it has the effect, therefore, of breaking down the spirit of domination and exclusiveness at present existing, which forbids the introduction of other methods than the crude and original ideas of Stephenson and Co., such a conclusion is well obtained at the expense and noise this inquiry has created, and must be regarded with satisfaction by every well-wisher to the railway system, and by none more so than by

AN OLD ENGINEER.

LETTER FROM WM. TURNBULL, Major U.S. Topographical Engineers.

It is with considerable pleasure that we publish the following letter received from a highly respectable and valuable member of the profession residing in the United States. We are happy in enlisting him as a correspondent to the pages of our Journal, and it will be a gratification to us to receive the other engravings of the Potomac Aqueduct promised by the Major, in order that we may be able to lay before our readers the progress of that work.

Washington City, Aug. 31, 1838.

Sir,—Several months ago, when a specimen number of your valuable journal was exhibited in this city, I became a subscriber; but, owing to the remissness of our booksellers, or the want of a proper agent here, I did not receive it until within a few days, when I received three quarterly numbers at once.

I feel highly flattered that you should have thought a description of the work (Potomac Aqueduct) under my charge, worthy of a place in your journal, and avail myself of the opportunity of our Charge d'Affaires to Belgium, M. Virgil Maxey, who visits London on his return to Brussels, to send you a copy of the drawings and description, which have been added to since the first publication.

There are still three or four more drawings, showing the condition of the work at the end of the year 1837, and some changes, suggested by our experience, made in the construction of the coffer-dams, which have proved of great utility, and which should accompany the description, but, unfortunately, they are yet in the hands of the engraver. I shall have the pleasure to forward them by the next opportunity that offers.

The subject of coffer-dams is one of peculiar interest to me. I remarked in the third number of your journal, a drawing and description of the coffer-dam to be used in the construction of the terrace-wall, &c. of the new Parliament-house, and hope that it will be in your power to give some details of the operations of emptying, &c., as that work progresses.

On examining the plan, I observe a great many iron bolts, passing through the puddling at different heights. I was once forced, by the spreading of the outer row of piles, to use bolts in a similar way, at low-water mark; and, as the puddling settled, a cavity was left under each bolt, through which the water found its way, and was the cause of very great inconvenience: the dam was filled with water several times by means of them.

I should be much pleased to know their effect in the coffer-dam for the new Parliament-house.

With my best wishes for the success of your journal, which, I think, bids fair to be of extensive utility.

I have the honour to be, Sir, very respectfully, your obedient servant,

WILLIAM TURNBULL,
Major U. S. Topo. Engineers.

MOMENTUM OF FALLING BODIES, COLLISION, &c.

SIR,—In further elucidation of my letter of last month, I beg to offer the following remarks, which I request you will be so obliging as to insert.

"Momentum is *said to be* (vide Hutton's Course of Mathematics, Vol. II, page 252, &c.) the power or force in moving bodies with which they strike any obstacle which opposes their motion:" and (page 314, proposition 149) *it is said* that "B being a body moving with the velocity V, $BV = M$ is the momentum with which it strikes another body b:"—and an exnmple is given of two bodies, B weighing 5, and b weighing 3, moving respectively with velocities $V = 3$ and $v = 2$, which, *it is said*, would, after collision, move with velocities $\frac{BV + bv}{B + b} = 2\frac{5}{8}$ if previously moving in the same direction; $\frac{BV - bv}{B + b} = 1\frac{1}{8}$ if in opposite directions, and $\frac{BV}{B + b} = 1\frac{7}{8}$ if b were at rest. Now I hold this to be incorrect. I conceive the momentum of a body moving with a given velocity, to be the *sum of two similar forces* ($m = \mu + M$), whereof μ is the force that acts to overcome the inertia of the body and is measured by its weight ($\mu = b$), and M is the force necessary to preserve the motion of the body at the given velocity; which force is in proportion to the product of the weight by the velocity (M is as bv).—From the experiment detailed in my last letter I conclude that $M = \varphi bv$, where φ is $> \frac{10}{7}$ and $< \frac{13}{8}$ nearly $= \frac{3}{2}$. Hence $m = b + \frac{3}{2} bv$; and v in feet per second $= \frac{2}{3}\left(\frac{m - b}{b}\right)$.—The following would be the working of the problem above quoted.

M the momentum of $B = 5 + \frac{3}{2}(5 \times 3) = 27\frac{1}{2}$. } where the formula
m ditto of $b = 3 + \frac{3}{2}(3 \times 2) = 12$. } is $m = b + \frac{3}{2} bv$.

Making use of these values of the momenta and the formula $v = \frac{2}{3}\left(\frac{m - b}{b}\right)$ applied to the various cases, we have

(I) $\frac{27\frac{1}{2} + 12 - 8}{8} \times \frac{2}{3} = 2\frac{15}{24}$ velocity when B and b moved in the same direction.

(II) $\frac{27\frac{1}{2} - 12 - 8}{8} \times \frac{2}{3} = \frac{5}{8}$ velocity when they meet.

(III) $\frac{27\frac{1}{2} - 8}{8} \times \frac{2}{3} = 1\frac{5}{8}$ velocity when B was moving and b at rest before the collision.

These resulting velocities are very different from those given in "Hutton's Course."—Experiment would decide which are correct. Were the experiment, detailed in page 18 of this Journal, repeated with good spring balances, and different weights let fall, a more exact value of φ would be obtained, and the formula $m = \mu + M = b + \varphi bv$ would be tested.

Yours obediently, B.

ERRATA.—Page 18, line 34, *for* $m = b + M^{bv}$, *read* $m = b + \varphi bv$.
" 49, *insert* between, *and read* equal to between 10-7ths and 13-8ths, &c.

WOODEN PAVEMENT.

SIR,—I was much gratified the other day, in passing along Oxford-street, to see that a comparative trial is about to be made of various kinds of pavement. It is only by laying down the different sorts in juxtaposition, on a much frequented thoroughfare, that any thing like a just estimate of their respective advantages can be made. I know not whether the works now going on are under one particular superintendance, or whether the laying down of each kind of pavement is confided to the particular persons whose interest it is to see that every precaution necessary to ensure success be attended to. This latter mode would seem not only the most natural, but the most desirable; for if each sort of pavement be not as perfect in its kind as it is possible to make it, the comparison will not be a fair one. Nevertheless, from what I have observed, it would appear really as if the persons directing the laying down of the wooden pavement were exerting themselves in behalf of their rivals, for never did I see work done in so slovenly and insufficient a manner. I must, however, premise what I have further to say by observing, that I am in no way whatever interested in the question of the relative merits of the different kinds of pavement; but I am acquainted, well acquainted, with the nature of wooden pavements, their advantages, and defects, and can affirm that no kind of pavement, perhaps, requires to be constructed with greater care.

1. The hexagonal blocks must be cut with mathematical exactness in all their dimensions.

2. The surface on which they rest must be not only perfectly even, but so solid and compact as not to be irregularly compressible into hollows. The latter circumstance, indeed, is necessary to all pavements.

3. The blocks must be dry when laid down, else, if they be much swollen by wet, they will contract considerably in drying, and the pavement be no longer solid, but ricketty. When laid down dry, the blocks will always be far enough from perfect contact to admit of such slight swelling as may result from rain falling on their upper surface.

4. The successive blocks of each successive range should be hard rammed down to a level, determined by a transverse rule laid on them from side to side, *before another row is placed*, so that if any block sinks lower than another by being rammed, it may immediately be lifted up, and fresh sand or fine gravel placed beneath it.

5. The cross-section of a wooden pavement should have but very little slope.

Now, Sir, every one of these essentials to a good wooden pavement is neglected in laying down the one in Oxford-street.

1. The hexagons are very different in size.

2. The surface on which they rest is one of a most irregularly-sized gravel, a mixture of large and small rounded stones; the very worst bottom that could be chosen for the purpose.

3. The blocks are quite wet when inserted.

4. The blocks are not rammed as laid down. I believe they will not be rammed till the space is all paved.

5. The cross section presents by far too great a convexity. The different size of the blocks is such, that in many places the faces are more than half an inch asunder, and the irregularity of the bottom on which they rest will make them very ricketty. If, while wet, such openings exist, what will there be in summer? The ramming will be done to make an even surface; but unless each block be driven down till it can go no further, the passage of carriages will soon make an uneven road of it; and if every block be rammed down to the utmost, the whole pavement, with much labour, must be beat down to a level, when any single block that may happen to go down lower than the rest.

If well made, the surface of a wooden pavement is so smooth that the slightest slope is sufficient to let the water run off. Too great a slope is very dangerous on a wooden pavement; for one of its inconveniences is its being exceedingly slippery in wet weather or in frosty weather; indeed, this I take to be the great disadvantage of wooden pavements for the *streets* of London (for *court-yards*, when well done, it is excellent); many a poor horse's knees will suffer from it, and the omnibus drivers, who already pull up their horses so suddenly that they slide a few feet on the roughest stone pavement, will find it impossible to stop suddenly, but by the wheels striking against the prostrate bodies of their cattle.

It is found that the mud of our streets is produced from the squeezing up of the subsoil. Now, this cannot possibly happen in a well-constructed wooden pavement, and such is, therefore, always free from mud in winter, and from dust in summer, both very great advantages. But the pavement, as laid down in Oxford-street, is so badly done, that it will soon be covered with our slimy mud, and no horses' feet, unless their shoes be made with iron spikes to them, will hold. Indeed the thing is done in so hurried a manner that it cannot be good. A clever workman cannot lay down more than two square fathoms of wooden pavement in a day, supposing the soil beneath all ready to his hand, and if the blocks are secured to each other by wooden pins, as is found advantageous in some cases, he will not do more than 49 square feet in a day.

The necessity of a good bottom is such, that in some places it has been found necessary first to lay down a good solid pavement, on which a perfect floor of two inch planking is laid down, this is smeared over with pitch, and finally, the hexagonal blocks are carefully placed and secured each to the other with wooden pegs. This is, of course, very expensive, and with us unnecessary, but a hard and perfectly even bottom should be made before laying down the blocks.

I could say a great deal more on the subject, having had opportunities of studying it, not from motives of interest, but from a love of information. I must, however, conclude this article, already, I fear, too long. Any information in my power to give I will be happy to communicate; my address may be learned of Mr. Weale, Architectural Library, Holborn. I am, Sir, your most obedient,

27th December, 1838. J. R. J.

[The above communication was intended for our last Journal, but was received too late for insertion. The wooden pavement in Oxford-street already indicates our correspondent's predictions; but the bad success of the experiment is not to be attributed to defects inherent in that kind of pavement, but to the unwarrantably careless manner in which it has been laid down; another cause of its failure may be attributed to the small space allotted for the experiment, the mud from the roadway at each end is brought on to it by the horses' feet and carriage-wheels, which keeps it constantly covered with mud or dust as the other pavement, whereas the great cleanliness of a wooden pavement is one of its prominent advantages, which can only be secured by having it for some distance.]

WHEELS OF LOCOMOTIVE ENGINES.

SIR,—I beg to submit to the consideration of the readers of your influential Journal, a suggestion on the construction of the wheels of locomotive engines, should you consider it of sufficient value to be admitted to your pages. It is simply to call attention to the feasibility and utility of employing brass as the material for those parts of the engine. We well know that in machinery generally, it is considered of great saving in wear and tear to prevent the contact of kindred metals, and perhaps it might be deserving of consideration how far the wear of the rails might be lessened by such an expedient.

Anything tending to promote this object I know will meet with attention; and it might perhaps be practicable by the use of brass wheels to save the expenditure of metal on the length of rails which are more difficult to repair, and therefore more expensive. I do not pretend to decide upon the utility of this suggestion or its actual economy in working, but perhaps some of your readers who are engaged in experiments on railways and have the means of trying it, might be induced to ascertain what would be the practical result.

In machinery, as you know, the contact of homogeneous metals is sometimes prevented by the application of leather, but it would be absurd to propose such an expedient for adoption on a railway on a large scale. It might, however, be well worth experiment on a small scale, as elucidatory the laws of friction, how far the application of leather or other substance to the wheels or rails, by producing a smoother surface, would be calculated to diminish the friction.

I am, sir, yours, &c.,
HYDE CLARKE, C.E.

STUART'S DICTIONARY.

SIR—In the last number of your useful Journal your correspondent, "A Constant Reader," while noticing Mr. Britton's Dictionary of Ancient Architecture, adverts to the deficiencies of preceding similar works; and, among others, he names "Stuart's Dictionary of Architecture." Having had the misfortune of projecting that compilation, I am desirous of your permission to say a few words in explanation of *some* of its manifold imperfections.

It was originally designed to contain a *general* collection of technical architectural terms, a popular history of the art in all countries, and biographical notices of architects; but the engagements of the publishers, urging a greater haste in publication than was consistent with a careful preparation of the manuscript, I found it impracticable, under the circumstances, to carry out the design to my own satisfaction. The labour of crude and undigested compilation became so irksome, that after hurrying a *few* of the first sheets through the press, and preparing about twenty-five of the engravings, I was glad to resign my share of the speculation. Feeling, however, the weight of my own faults, I was unwilling to run the risk of being loaded, in addition, with the editorial sins that might possibly be committed by my successor, and I therefore stipulated that the name of another Editor should be substituted for mine in the future parts of the compilation. Some time after this the publishers became bankrupt, and I thought the book had deservedly died, as it "made no sign." The letter of your correspondent first informed me that it had subsequently been revived, and continued, and that too under the original title. A peep, a few days ago, into the truly "finished" Dictionary of Architecture, by Robert Stuart, makes me anxious to assure the "Constant Reader" that I am utterly innocent of nineteen-twentieths of its nonsense and plagiarisms. Should any of his friends be simpletons enough to buy the volumes, in the hope of finding that kind of information which the title pages say they contain, and in the bitterness of disappointment, proceed from damning the book to perform the same duty towards its authors, I entreat the "Constant Reader" to interpose his friendly offices, and direct that one-twentieth part only, and no more, of the deserved maledictions shall rest on my devoted head in time coming. I am sure he will feel the reasonableness and justice of my request, when he reflects that for several years past I have, unknown to myself, borne *all the blame* of compiling that miserable production. I am, sir, your obedient servant,

ROBERT STUART.

London, 22d Jan. 1839.

ON ARCHES BUILT IN CEMENT.

The custom of turning arches in cement has now become very general with engineers, more particularly where great strength is required, as culverts under heavy embankments, and arches of a flat elliptical form. It appears questionable whether the additional strength acquired by turning arches in cement is real or imaginary; taking into account the great liability to fracture in all brick structures built in cement, the least settlement occasions a fracture, by which the adherence of the cement to the brick is totally destroyed, but which would not be the case did the cement possess any yielding properties, as common mortar.

In some cases I have observed arches turned in mortar, and a few feet at the crown only built in cement; and again elliptical arches built in mortar as high as the haunches, and the remainder in cement: this latter method will doubtless allow the arch to settle in a slight degree without detriment, in which case it would merely have the effect of forcing out some portion of the mortar joints; that part in cement remaining a compact mass, any rupture in which would occasion its destruction. A slight percussive force will often have the effect of rupturing a wall in cement, which would be comparatively harmless if built in mortar.

It has often occurred to me, and I now respectfully submit it to the notice of engineers, whether in the case of an arch being turned in cement, it would not be preferable to have mortar joints in each ring running quite through the arch, which I suppose would allow of some considerable settlement to take place without injury to the structure:—say in the case of a brick arch having three or more courses in the first half brick ring turned in cement, and as many courses in the remaining rings as necessary to allow of a continuous mortar joint from the soffit to the back of the arch. The part in cement assimilating to a string course in masonry. I imagine that this method of construction would possess many advantages over that in present use—especially where there would be reason to suspect a subsidence of the abutments.

PETER BRUFF.

Charlotte Street, Bloomsbury,
January 20th.

BENNETT'S NEW STEAM ENGINE,

FOR CAPTAIN COBB'S STEAMER.

We make the following extract from a pamphlet, forwarded to us from America, entitled "*Atlantic Steam Ships*":—

This vessel, built under the immediate superintendence of Captain Nathan Cobb, and intended for the Liverpool trade, is now completed, and will be ready for her first voyage across the Atlantic on the 10th of June (1838).*

This enterprise was planned and decided upon by Captain Cobb (then of the Liverpool packet Columbus) in 1834. He memorialized the legislature on the subject, without success; but, determined to test its practicability, he entered into a contract with Mr. Phineas Bennett, of Ithaca, to supply the machinery for his intended vessel before the 15th November, 1836. Various delays, however, occurred in performing the same—the engine being constructed on a principle entirely new, the sole invention of Mr. Bennett; but, had the contract been duly fulfilled, Captain Cobb's vessel, having been built upwards of two years, would doubtless have reached the English docks several months before the first voyage of the Sirius to this country.

Presuming the annexed description of her engine will interest many of our readers, we copy it entire:—

This engine has undergone the scrutiny of great numbers of scientific professors, ingenious and experienced mechanics and engineers, citizens and strangers; and the examinations have resulted in a general conviction that the world is about to realize a new improvement, not inferior to that of Watt and Bolton—an improvement that will effect a new era in ocean navigation, and bring all parts of the world in approximation to each other. A voyage to Liverpool, it is believed, may, by the power of this engine, be accomplished in ten days, and with only *one-tenth* of the fuel heretofore required, thereby allowing more room for passengers and freight.

The following description and drawing, it is hoped, will fully explain how the fire and the water can be brought and continued in actual contact with each other, and, rapidly generating the steam, still kept in controul, and its potency safely directed to propel the ship, or other object to which it may be applied.

The engine for Captain Cobb's Liverpool steam-packet, is a double horizontal high-pressure engine, thirty-five inch cylinder, and six feet stroke, with two blowing cylinders, of half the capacity, worked by the piston-rod of the steam cylinder passing through the lower or extreme head, and into the blowing cylinders; consequently, both will be of the same motion.

* We have not yet received any intelligence of this vessel having been completed or ready for her intended voyage.—ED. C. E. & A. JOUR.

References.—Pipes, C, with the necessary valves attached to the blowing cylinders, convey the air to the steam generator, whose outer case, *a*, *a*, is four feet diameter, and twelve feet high, and the inner case, or furnace, B, is three and a half feet diameter, and nine feet high. Smoke and feed-pipe, D, is constructed with two slides, *e*, *e*, which closes the pipe perfectly tight when thrust into it—their uses will hereafter be explained; *f* is a cap-valve in the steam chamber, placed over a short pipe or nozzle on the upper head of the furnace, and fitted to its seat perfectly tight, with a rod extending through the upper head of the outer case; *g* is the ash-pit below the grate; *h*, an opening into the ash-pit, with a slide to close it tight, when necessary.

In order to put the engine in operation, and successfully use all the advantages of this generator over any other, it will be necessary to set open the feed and smoke-pipe D, and the pipe *h*; introduce fuel down the feed-pipe, in sufficient quantity, and ignite it. Previously fill the space between the outer and inner case with water up to the dotted line, half way up the cap-valve *f*, which will completely immerse the furnace; and when steam is generated of sufficient elasticity to start the engine, say seventy-five pounds per square inch, close the pipes D and *h*, with their respective slides; then start the engine in the usual way, by opening a communication with steam-pipe *i*; then the blowing cylinders will force their charges of air through the pipe C into furnace B, partly taking its course through the mass of fuel on the grates, a sufficient quantity being introduced above the fuel to burn the smoke, which can be regulated by slides in the branch pipes, terminating the air-pipe C. You will discover that there is no escape for the air thus forced into the furnace, until its elasticity is, by the continued blast from the blowing cylinders, a little superior to the steam in the steam chamber, when the cap-valve *f* will rise from its seat, and the air, flame, and gases arising from combustion will be forced to pass under the edges of the said valve out into the water; and in this process all the heat generated will be imparted to the water, without the possibility of escaping otherwise.

By the repeated experiments I have heretofore made, I find that one foot of air blown into the furnace to promote combustion, by the expansion it undergoes, and by the addition of the gases and steam, is augmented in bulk at least five times its original size, or, to speak briefly, there is five times as much compound steam as air forced into the furnace; consequently, it will take one-fifth part of the power of the steam to operate the bellows, *plus* the friction, or this is nearly the power; but I forbear at present, nor is it necessary, to speak at large on that subject in this paper.

By a careful examination, it will be seen that the pressure of steam will wholly depend upon the proportion of the size of the blowing cylinder to the steam cylinder. In my engine now building, the blowing cylinders each contain twenty cubic feet, the steam cylinders each forty feet; but the steam being cut off when the piston has made but one-half its entire stroke, which reduces its size, as a measure to deal out the steam, to exactly the size of the blowing cylinder, the measure of the air forced in by the blowing cylinders being augmented, by passing through the generator, to five times its bulk, has to be forced into a space in the steam cylinder of just its original bulk; it will, therefore, exert a force equal to five atmospheres, which will be sixty pounds to the square inch above the atmospheric pressure.

This force, per inch, will not be exerted during the whole length of the stroke of the piston, but only half way, or to where the steam is cut off; and at the end, its elastic force is reduced to about twenty pounds, which will make the average pressure fifty pounds per square inch, and the piston contains 962 square inches, which multiplied by 50, will produce 48,100 pounds—the whole average force the piston moves with. It is calculated to have the engine make thirty-five double strokes per minute; hence, the piston will move 420 feet per same time, which multiplied by 48,100, produces 20,202,000 pounds: the weight that the piston would lift one foot high per minute, divided by 33,0001 being what a horse-power is estimated at, gives 612 horse-power for each steam-cylinder. But the power abstracted to operate the blowing cylinders and overcome the friction, I allow nearly equal to the power of one of the cylinders; therefore I estimate the power of the engine at 612 horse-power.

The amount of fuel consumed will depend upon the amount of air forced into the furnace by the blowing cylinders, and my two blowing cylinders, at every revolution, would force in 80 feet, if there were no leak either in piston or valves, and no space between said piston and valves for the air to compress in, and not be wholly forced out; therefore, probably not more than 75 feet will be expelled each revolution of the engine; and as it takes all the oxygen contained in 175 feet of atmospheric air to burn one pound of carbon, and 525 feet to burn one pound of hydrogen, I am of opinion, that to allow 225 feet to be necessary to burn one pound of fuel, will not be allowing too much; and, as before stated, 75 feet will be forced into the furnace at each revolution, it will therefore take three revolutions to burn one pound; and, as a cord of yellow pine weighs about 2,100 pounds, it will take 6,300 revolutions to burn one cord, which, divided by 35, the motion of the engine per minute, will give three hours for each cord—which, compared with the engine of the steamer Erie, on the Hudson, of little less or nearly the same power (600 horse-power), will consume forty cords in ten hours, or twelve cords in the same time my engine will one cord.

RESTORATION OF GOTHIC WORKS IN AUSTRIA.

We find that the attention of the Austrian government has been attracted from the research of classical ruins to the restoration of their own fine Gothic monuments, some of which threatened to be equally lost. When we remember the expense which was employed in the antiquities of Pola, Spalato, Aquileia, Trieste, Venice, Verona, &c., we are justified in entertaining great expectations from this zeal for their national architecture. We do not know whether this is one of the fruits of the French mania for the Renaissance, but at any rate it forms an accession to the extension of that taste for the Gothic, which already in France and Northern Germany seem to promise the revival of this glorious style. Few countries are more interesting than those of the Austrian empire to the student of medieval architecture, for they stand upon that debatable ground where the Moorish and the Byzantine influence both exercised control, and where the churches are not less interesting from proper Gothic monuments, than from the relics of those arts which Greece, even when expiring, poured forth on the western world.

SOUTH EASTERN RAILWAY

WORKS NEAR DOVER.

Communicated by an Engineer on a tour of inspection of the Public Works in Great Britain.

The works upon this line of railway, under the charge of Mr. Cubitt, are now proceeding with vigour, and present a thorough business-like appearance, indicating a decision on the part of the company to complete with as little delay as possible this line of railway, which, as the great continental outlet of the kingdom must, when completed, assume an important station among the principal lines of internal communication.

At Dover the works which are under the charge of Mr. John Wright as resident engineer, are very extensive and also of peculiar interest; they consist of the formation of double (or parallel) tunnels, together with open galleries along the face of the extensive and magnificent range of chalk cliffs which extend from the harbour at Dover to the Martello towers eastward of Folkstone. This very interesting portion of the line is being divided into six spaces of unequal extent, three portions appropriated to tunnels, two to the open galleries alternating with the tunnels, and the sixth to an open cutting along that remarkable place the Warren, which is an undercliff occasioned by a settlement of the chalk strata during one of those great convulsions of nature, which causing both subsidence and elevation of the crust of the earth, has put us in possession of her internal wealth, and given to the science of geology its high importance.

The eastern tunnel terminates at the Dover side of Shakspeare's cliff, where the cutting to form the face of the tunnel will be about 110 feet, the immense masses of chalk rock required to be removed from this spot, and from so great a height, has led to a very extensive use of gunpowder for this purpose, and masses containing upwards of one thousand cubic yards of chalk are at one blast precipitated from the summit to the beach below, there to be levelled for the formation of an embankment leading to the terminus on the quay. We were fortunate enough to witness two of these blasting operations on the 12th of January, the masses to be removed were nearly cubes containing about 700 yards each, and isolated from the great body of the cliff, by excavating from behind them a sufficient space for the workmen to pass and repass conveniently; at the foot of the mass to be overthrown, in the above-named excavation, two borings were made downwards, forming an angle of about thirty degrees with the perpendicular, each boring being fifteen feet deep; these were then filled, first with six inches of tow at the bottom, then 50lbs. of gunpowder was poured in, and lastly the holes were rammed to the top with rubble chalk around an iron rod, which, upon being withdrawn, left a hole from the surface to the charge to contain the priming, which consisted of fine gunpowder; in one of the holes of the second mass to be overthrown, the priming was conveyed to the centre of the charge by a pewter tube ¼-inch bore, similar to those used as gas pipes: this was done by way of experiment, and appeared to answer better than priming in the common way, which communicates with the top of the charge only instead of the centre. When all was ready and the order for firing the train given, a most animated scene presented itself along the extensive face of the cutting the workmen, amounting in number to about 170, were seen scrambling and climbing along the almost perpendicular face of the cliff, to attain a respectful distance from the scene of action. In a few seconds after the ignition of the train, a rumbling sound, like that of extremely distant thunder was heard, and the next instant the whole mass was lifted bodily from its base, and in falling again, it cleft asunder from top to bottom, and opening, crumbled to fragments, which poured like a torrent down to the beach. The charge being inserted obliquely (below the mass to be overthrown, as before described), at the same time that it lifted it up, forced out at least 300 yards from below its base, making a total of not less than one thousand cubic yards of chalk removed with one blast, and if both charges had gone off simultaneously, as was intended (there having been a perceptible interval between the explosions), a much greater effect would in all probability have been produced, as it was, however, estimating it at 1000 yards, and allowing the specific gravity of chalk to be 2·3, as stated by Dr. Mantell, we have for the weight of chalk thus removed with 100lbs. of powder, no less than 1,748 tons. In a few minutes after the first explosion, the signal for firing was again given, and the second mass similarly followed the first; thus this immense work, which if executed by manual labour only would be very costly, is now carried on at a comparatively trifling expense both of time and money.

The double or parallel tunnels are being formed by first drawing a heading six feet high and four feet wide, the top of each heading being within two feet of the intended roof of the tunnel, the headings are worked in opposite directions from shafts sunk from the surface above, and the excavated chalk is removed by side headings or driftways at right angles to the direction of the tunnel and leading to the face of the cliff, where it is thrown into the sea; a trainway is formed along these drifts having an inclination of 1 in 30; the waggons when loaded from the heading are easily pushed by one man down the trainway to the face of the cliff, he teems its contents into the sea, and upon such an inclination is easily able to push the waggon back again into the workings for another load; by such judicious arrangements the cost of the earthwork of the tunnels is reduced very considerably, compared with that of similar great undertakings. Upon an examination of these works we could not but notice the precision with which the direction of the various headings had been preserved during the excavation, for we could not discern the least deviation from the right line where the workings met from opposite directions.

REPORT OF THE ENGINEER TO THE DIRECTORS OF THE LONDON AND BRIGHTON RAILWAY.

Gentlemen,—The state and condition of the Works up to the present time are as follows:—

On Contract, No. 1.—The contractor has completed the bridge at Combe Lane, and has cut through the high ground in the late Mr. Chollett's land, and formed the embankment across Birdhurst Lodge, and cut through the hill beyond, and built a bridge over the lane on the south of the hill, and the embankment is carried some way over this bridge.

An occupation bridge is also built, and the road formed under it. The Works here are so well put together, that the temporary rails will be immediately laid down for half a mile, and then the long embankments will be more rapidly proceeded with.

The works are also commenced at the junction with the Croydon railway up to the cross-roads at Croydon common, and the contractor has laid in a large supply of materials for the remainder of the bridges, which will be commenced as soon as the weather is sufficiently settled. There are at present employed on this contract 170 men and 13 horses.

Contracts, Nos. 2 and 3, are let to one contractor. All the cuttings but one on No. 2 contract are in active execution: the Coulsdon-road bridge, and the occupation bridge No. 5, are nearly complete; the approaches will be finished in a few days: the culverts and brickwork are all in progress, and the temporary rails will in a short time be laid upon a great portion of the work.

Considerable progress has been made in the excavations of No. 3 contract, and although the contractor ought to have done more work in the time, yet the want of lodging and accommodation for the workmen has been a great drawback to him, but as buildings are now erected for the extra accommodation of above eight hundred men. I shall compel him to use his utmost exertions.

There are at present, however, employed on these two contracts seven hundred and fifty-four men, and thirty-two horses.

Contract, No. 4.—Merstham Tunnel.—The contractor has got all the shafts but one sunk to the bottom of the Tunnel, and that one is sunk to the level of the top of the Tunnel.

The driftway between the shafts is in progress, that between the trial shaft at the north end of the Tunnel and the first working shaft is completed, as well as the driftway between the trial shaft at the south end of the Tunnel and the last working shaft. This Tunnel is perfectly free from water, and the chalk is exceedingly hard and compact.

There are at work on this contract 162 men and 9 horses.

The extra contract at Merstham for the diversions of the turnpike road is proceeding in a satisfactory manner, although the contractor was at first delayed by not having possession of the Merstham tram-road.

There are 120 men and 36 horses at work on these roads.

Contract, No. 5.—The contractors have been at work little more than one month, and they have commenced upon cuttings Nos. 1 and 2, and on the side cutting for the large embankment on Earl's Wood common. The bridge over the mill-stream at Merstham is nearly completed, and they are proceeding in a very satisfactory manner. I am informed they will have possession of some land they require for temporary purposes in about a week, when they will be enabled to make greater progress.

There are 337 men and 28 horses at work upon this contract.

Contract, No. 6.—The contractors have been at work on this contract about one month, and as they have only possession of part of the land, are obliged to confine their operations to the side cutting on the Low Lands at Horley. They have fenced off most of the land they are in possession of.

There are at work on this contract 158 men and 10 horses.

Contract, No. 7.—The contractor is at work upon the cuttings that will require the longest time to execute, and is going on in a very satisfactory manner. About three miles of this contract, is of so light a description of work, that it is not necessary at present to enter upon it.

There are at work 220 men and 10 horses.

Contract, No. 8.—Balcombe Tunnel.—There are five working shafts at this Tunnel, besides two trial shafts which are sunk down to the bottom of the Tunnel, as well as two air shafts: one working shaft is finished. Two others are sunk down within five yards of the top of the Tunnel, another within 14 yards, and the third within 20 yards, and they are all proceeding night and day.

The water here has been found in greater quantities than I anticipated, I have therefore caused an adit to be driven up from the Brook Course, about 350 yards long, which is finished, and has tapped the water at the level of the bottom of the Tunnel, which it carries clear off the workings as fast as we get them opened out.

The driftway at the south end of the Tunnel has been completed to within a few yards of the first working shaft, and lays the work dry as it proceeds. The driftway is also going on between the north trial shaft and the northern working shaft. The total length of driftway at present complete is 280 yards in length. When the driftway is finished the whole of the water will run off of itself, and the Tunnel for ever afterwards be perfectly dry.

The contractor has at present 225 men and 15 horses at work upon this contract.

Contracts, Nos. 9, 10, 11, and 12.—These contracts are all let, and the contractors are actively engaged in casting up brick earth, preparing materials and getting them to the ground, to commence the work immediately the weather will permit.

Contract, No. 13.—This contract was entered upon last September, and the contractor has pushed on the work with spirit, and has made a considerable advance with the cuttings and embankments. He has completed and ballasted half-a-mile of road, ready to receive the permanent rails, which are in course of delivery. He has also a very large quantity of temporary rails.

The contractor has 300 men, 30 horses, and 60 waggons at work on this contract.

No. 14 Contract—Clayton Tunnel.—There are 10 working shafts at this tunnel, besides a trial shaft at each end; five of the working shafts are complete, four are sunk to the top of the tunnel, and the remaining one is within about 18 yards.

In sinking the trial-shaft at the north end of the tunnel, an impervious strata was found cropping up to the north, which prevented the water running off. I therefore ordered an adit to be driven up from the low ground to the trial shaft, which when cut through the impervious strata on a level with the bottom of the tunnel, will let off the whole of the water, and no more can in future accumulate.

The driftway between the shafts is being driven, and has been opened out between two of them. The chalk is firm and hard.

The contractors have at present 143 men and two horses at work on this contract.

The Company have obtained possession of lands for making bricks for the Tunnels and other works at convenient situations, and brick earth has been cast up, and early in the spring there will be a large supply ready for use.

Contracts, Nos. 15, 16, and 18.—These contracts extend from the south end of the Clayton Tunnel to the station at Brighton, as well as the station itself, and are all now advertised, and will be let on the 14th of March next.

Contract, No. 17.—The Shoreham Branch.—The contractor has proceeded much to my satisfaction. He has got most of the bridges built, several cuttings are opened, and the embankments formed, $2\frac{1}{2}$ miles of road are formed; the ballast is being put upon it, and the permanent rails will be laid down immediately.

A locomotive engine has arrived at Shoreham, which will be at work upon the line as soon as the rails are laid. This will materially expedite the forming of the embankments, and I expect this contract will be completed in September next, when the Shoreham branch will be opened to the public, which will be of great advantage in conveying materials for the main line. The contractor has at present 280 men and 40 horses at work.

A large supply of rails, blocks, sleepers and chairs have arrived, and more are daily expected.

The following is a summary of the number of men and horses employed on the whole of the works:—

	No.	Men.	Horses.
On Contract	1	170	13
	2	468	23
	3	286	9
	4	162	9
Turnpike-road diversions at Merstham		120	36
On Contract	5	337	28
	6	158	10
	7	220	10
	8	225	15
	13	300	30
	14	143	2
	17	280	40
Total		2869	225

This amount is exclusive of men casting and preparing brick earth.

The works now let and in operation extend over a distance of $41\frac{1}{2}$ miles, and are to be finished by the middle of August, 1840; and I cannot conclude this Report without expressing my satisfaction at the rapid progress of the works. I am, Gentlemen, your most obedient servant,

London, Jan. 16, 1839. JOHN U. RASTRICK.

GREAT WESTERN RAILWAY.

[We trust that the importance of the following reports will be a sufficient justification for having occupied so many pages of the Journal. We had intended to have made some remarks thereon, but in consequence of our correspondent, "An Old Engineer," having so ably commented upon them, we have refrained, for the present, saying any thing further on the subject.]

EXTRACTS FROM MR. WOOD'S FIRST REPORT.

The increase of gauge has been from 4 feet 8½ inches to 7 feet, and the prominent reasons assigned for such a departure from the common width, is the attainment of a higher rate of speed—increased lateral steadiness to the carriages and engines—a diminution of the friction by the use of wheels of a larger diameter—and a greater space afforded for the works of the locomotive engines.

The deviation from the ordinary mode of constructing the railway, has been the substitution of continuous longitudinal timbers, with piling at certain intervals, and cross transomes; with iron rails of a particular form screwed down upon the longitudinal timbers.

The additional width of gauge has increased the breadth of the entire track of the railway between the outside of the rails of the two lines (including the breadth of the rails) from 16 feet 3 inches to 20 feet 10 inches; consequently all the works connected with the formation of the road will be increased to a certain extent, but not in proportion to the above figures. The plan of continuous wooden timbers and piling also involves an additional cost beyond that of forming railways according to the ordinary method.

The questions submitted to me for consideration, therefore, appear to me to be shortly these; are the advantages professed to be obtained by this departure from the ordinary plan of construction of railways and increased width of gauge, realized? to what extent—at what additional cost—and are the advantages an equivalent for the increased cost of forming the railway according to this plan, viewing the whole subject in connection with the present state of the works?

Acting upon the principles hereinbefore explained as to the mode of conducting the inquiry, it was my object, as much as possible, to subject all, or as many as could be, of the properties of this railway as contrasted with others, to direct experiment; certain advantages are stated to be derived from this departure from the ordinary width and plan of constructing railways, and the circumstance of 23 miles of this railway having been opened, and having been in operation since the 4th June, appeared to me to afford an opportunity of subjecting to the test of experience, and of obtaining correct and indisputable results by carefully conducted experiments, *that which rested on conjecture, or casual observation.*

It is perfectly true that a daily opportunity has for some time existed of observing the rate of travelling with the passenger trains on your railway, by which some result of the rate of speed accomplished, or likely to be realized when a greater length of line was opened might be obtained, but the engines on the Great Western differ in many respects from those employed on other railways, and also from each other; if, therefore, extended observations had been made on the rate of travelling, it was necessary to distinguish what was due to the road, and what to the engines, and if any increased speed or greater performance was accomplished, whether such was applicable to the railway itself, or to the particular construction of engine only, and whether, by the application of similar engines to other railways (if practicable), the same results would not accrue.

If this had been done, no doubt important and valuable information would have been obtained, but that would have been, in fact, the very sort of inquiry by your own people, which you have determined to entrust to others; and it may be remarked, that if the inquiry had been conducted by yourselves, it could not have been at all conclusive or satisfactory in the comparison with other railways, and without such comparisons it would have been useless.

At the first outset of the inquiry, it therefore appeared to me necessary to institute a set of experiments, to ascertain the actual performances of the locomotive engines upon your own railway; with this information carefully obtained we then had the real working powers of the railway; by employing heavy loads, we obtained correct data for determining the maximum weight which the engines, then upon the railway, could drag, at determinate rates of speed; and by subjecting the engines to very light weights, we likewise determined the maximum rate of speed with certain known loads; and by recording the quantity of coke consumed and water evaporated in each trip, we also ascertained, with considerable accuracy, the comparative cost of motive power in dragging different loads at different velocities.

These experiments appeared to me to be highly necessary and valuable, inasmuch as whatever difference of opinion might exist (in the absence of correct experiments to ascertain the fact) as to the friction of the carriages, or resistance of the road as compared with others, these experiments, by determining the real practicable expense of working the railway, would at once ascertain what increased rate of speed could be accomplished, and at what additional cost of motive power such higher rates of speed was attained. These experiments would, in fact, anticipate, so far as the powers of the engines reached, the experience of some years of regular work upon the railway, and with more correct results, On my arrival upon the line on the 17th instant, I therefore commenced a series of experiments on the working powers of the engines, which were continued under my own observation during the ten days I remained there, and are now in operation, and will shortly be completed by persons in whom I have perfect confidence.

It would be premature, to say the least, at this stage of the inquiry, to give any results derived from experiments not yet complete; but it may be some gratification to the proprietors of this great work to state, that one of the engines, the North Star, accomplished an average performance from London to Maidenhead and back, of dragging 180 tons, including engine and tender, at the rate of nearly 30 miles an hour, and that on some occasions, for short distances, a rate of 45 miles an hour was attained.

When the powers of the locomotive engines and capabilities of the Great Western Railway are thus obtained, in order to comply with your instructions, and contrast this information with the capabilities of other railways, it will be necessary, in order to arrive at correct and conclusive results, that we should have the result of a similar set of experiments made upon railways of the ordinary construction. Although isolated experiments have been made by different individuals on several railways, and although I have made several myself, it does not appear to me that a set of experiments have yet been made sufficiently extensive and varied to fully develope the capabilities and powers of other railways, so as to form indisputable data for contrasting with the experiments made upon the Great Western. The directors of the London and Birmingham Railway, in the most liberal manner, granted me full permission to make any experiments on their railway, consistently with the noninterruption of their traffic; and Mr. Robert Stephenson, the engineer in chief, kindly assisted me all in his power, and furnished me with some experiments he had made on that railway, on a former occasion. I deem it, however, my duty to state to you that I do not think the information I am in possession of is sufficiently extensive or conclusive as regards other railways to enable me to make a comparison with the performances of the engines on the Great Western, so as to arrive at an incontestible conclusion, nor do I think it right that I should go into a comparative statement at all, unless the data be equally conclusive or carefully deduced on both sides. The information I at present possess does not enable me to go further than report to you the performances of your engines on the Great Western Railway; and if it be your wish that I should comply fully with your request, and contrast their powers with the performances on other railways, it will be necessary that some experiments, similar to those performed on your railway, should be instituted on some of the ordinary railways of a different width of gauge. It will not be necessary that the experiments on those railways should be equally numerous, as the engines on the other railways are generally of one description, and consequently one or two sets carefully conducted will be sufficient. It may be asked what practical advantage will result from all these experiments to the interest of the proprietors of the Great Western Railway? The answer is shortly this: it is admitted that the construction of that railway involves an increased capital; it is, therefore, quite necessary to determine what are the additional advantages, in a practical point of view, resulting from this mode of construction, and whether the advantages are greater or less than are equivalent to the increased cost of construction.

These observations apply more particularly to the plan of construction of the Great Western Railway generally, and to the capabilities of the entire system, or to the increased gauge, and the mode of construction combined; but it is not necessary to the adoption of an increased gauge, that the railway should be constructed on the plan adopted by Mr. Brunel; it may be constructed on some modified plan of that system, or it might even be constructed on the plan of the London and Birmingham, or Grand Junction railways. Neither is it absolutely necessary, if an increased gauge be deemed advisable, that such increased gauge should be precisely seven feet; all these are separate and distinct questions, requiring different and distinct investigation, and, therefore, the simple acquirement of correct information of the comparative capabilities of the Great Western Railway in its present state, with the other existing railways does not appear to me to comprise the whole question; it appears to me to admit of inquiry whether the width of gauge adopted by Mr. Brunel is or is not that which conduces most to accomplish all the objects for which a departure from the more established width was deemed advisable, and also whether the mode of construction of the railway is the best that can be devised, or in what way it can be improved, consistently with the objects required to be attained, and with due regard to economy.

The plan adopted by Mr. Brunel, as previously stated, consists of longitudinal timber bearings secured by piles at proper distances, with cross transomes, double at the joinings of the longitudinal timbers, and single at the intermediate piles; and upon these continuous bearings iron rails of a particular form are fastened by screw bolts.

It has been alleged that one of the objects of the increased gauge was a greater stability to the carriages, and consequently less vibratory, or greater smoothness of motion to the passengers; it appears to be, therefore, one of the subjects of inquiry how far this is realized,—whether such a desideratum is accomplished,—and to what extent. Keeping in view the principle set out with in this inquiry, of, if possible, subjecting to experiment mechanically every minutia, rather than to rely on opinion, or the more fallacious evidence of our senses, I had constructed an instrument for measuring and recording upon paper all the oscillations or vibrations of the carriages, from one end of the line to the other; and by transferring this instrument to the carriages of the ordinary railways, incontrovertible evidence is obtained, and such as can be appreciated by any one, of the relative vibratory motion of the carriages on the Great Western Railway, compared with the motion on other railways.

We have thus produced a diagram upon paper showing the number and extent of the vibrations of the carriages, and hence it can not only be ascertained if there does exist less motion on this railway than on others of a less width of gauge, but to what extent: and this is thus made capable of being a subject of arithmetical determination.

It was soon found, however, and this shews the importance of this mode of investigation, that the motion of the carriages on railways was a compound one; that besides a vertical motion, it was composed of an horizontal oscillatory motion and of a transverse undulatory motion combined; and it appeared, so far as we could depend upon observation, that less of one description of motion existed on the Great Western Railway, and more of the other, than upon the ordinary railways; it therefore became necessary, and of some importance, to measure and determine each of these motions distinct from the other, not merely for idle curiosity, but for the purpose of ascertaining the causes of each, and having done so, to attain the first step towards accomplishing a remedy. All this applies to the compound action of the rails and the carriages; and it will be seen that such a complication of motions required not only time but extreme labour and attention to investigate.

We now come to, perhaps, the most important consideration, that of the construction of the railway; this is the substitution of longitudinal continuous bearings of timber, with piling, instead of isolated stone blocks, or transverse timber sleepers, or, indeed, continuous timber bearings without piling.

The investigation of this part of the subject, according to the principles laid down in this inquiry, was attended with extreme difficulty.

The first subject for investigation was, the relative firmness or solidity of base exhibited by the continuous bearings of timber with piling, and compared with stone blocks, or continuous bearings without piling; to determine this, I had an instrument, or deflectometer, made, which being placed underneath the rail, measured the amount of deflection when the trains or known weights passed over, and the more accurately to determine the precise action of the load in passing over the rails, I employed three deflectometers at the same time. The motion of one with the other was effected by a rod between each instrument, one was placed underneath each of the supports or transomes opposite the piles, and one in the middle of the rail; and by a similar contrivance to that employed in the instrument for measuring the oscillation of the carriages, I got a tracing of the deflection of the rails recorded upon paper, and thus obtained correct diagrams of the deflection at each of the places at the same moment of time.

By subjecting the rails with piling in all their varieties, and also continuous bearings of the same scantling of timber without piling, to the deflectometer, I obtained a measure of the relative firmness or solidity of base of these two varieties of construction; and by likewise employing the same instruments to measure the deflection of the rails and depression of the blocks, or cross sleepers, on other railways, I thus obtained the relative firmness of base of all these different modes of construction, and these diagrams being capable of being transferred to, and embodied in a report, and measured with undoubted accuracy, will enable any one to pass their own judgment upon the relative firmness of base of those different plans. It will at once, however, be seen, that admitting we have obtained the relative firmness of base of the existing plan of construction of the Great Western Railway compared with that of known plans of construction of other railways, the degree of stiffness developed by the former, comprehends both the section of the timbers, and that of the rails; and that such a plan of continuous bearings, either with or without piling, does not necessarily imply the use of that particular form of iron rail; it was therefore necessary to determine what part of the deflection was due to the timbers and what to the particular form of rail. To accomplish this, I purpose having these rails removed, and the same rails which were subjected to experiment on other railways, where stone blocks or cross sleepers were used, substituted; when the deflection will be again measured. By a combination of these experiments in all their varieties, I expect to arrive at results which, not being matter of opinion, but facts, deduced from carefully-conducted and self-recording experiments, cannot fail of producing the most important if not conclusive results.

Independently of those experiments, to elucidate all the minutiæ of action of the different parts of the system of railway mechanism, and others, which it is not necessary at this time to enumerate, I subjected to experiment, so far as the means and circumstances afforded me, the resistance and friction presented by the Great Western Rails to the passage of the carriages and engines along them; and by pursuing a similar course of experiments on other railways, we shall thus have valuable corroborative evidence to that of the experiments made with the engines, of the relative resistance of the Great Western Railway, compared with that of railways of the ordinary width.

With the exception of some experiments on the London and Birmingham Railway, made on my survey, and which were not sufficiently varied or sufficiently numerous to afford conclusive results, we still require further evidence of the resistance of the carriages and engines on other railways, to compare with those made on the Great Western Railway, in order to arrive at conclusive results, or indeed to enable me fully to comply with my instructions for this inquiry.

REPORT OF JOHN HAWKSHAW, ESQ.

To the Directors of the Great Western Railway.

GENTLEMEN,—Your instructions of the 5th September are to the following effect:—That you are desirous of obtaining my assistance in coming to a sound and practical conclusion as as to your future proceedings, directing my attention to those points which may be said to constitute the peculiar features of your railway, as contrasted with others, including the construction and efficiency of your engines, as well as every matter connected with the locomotive department.

My attention is also called to the bridge at Maidenhead, as to its construction generally, and as to the means proposed to remedy an existing defect in one of the arches. To arrive at an opinion, I am desired to undertake an examination of that portion of the line now completed, and investigate the result of the whole system which has been adopted.

To come to a proper conclusion, it appeared to me to be necessary that I should make myself acquainted with the general character of the whole line, and consequently I have been over its whole length to Bristol. It seemed also desirable that I should inform myself, as accurately as possible, as to the traffic to be expected upon it generally, and in the aggregate, for this certainly forms one of the most essential features of all lines.

The question seems also to require a still more extended view than this; the district into which it goes has to be glanced at; the area and extent of population, which may be looked to for collateral traffic, has to be seen; and these have to be compared with districts through which other lines have been made, and where other lines are at work.

The necessity of such a view of the question became apparent to me, because, on coming first upon your road, that which immediately strikes is, the enlarged capacity of all things, engines, carriages, and road. And the existence of such an arrangement pre-supposes, in my view, an equally enlarged traffic; trains of much greater weight, and of a greater number of passengers than elsewhere. In short, though not to an equal degree, the difference between your arrangements and those of other railway companies, is something like the difference between a canal for barges and a canal for ships; and this comparison will not be extraordinary, should it appear that, taking your gradients into the question, your locomotives have twice the power of those on other lines; and the contrast will not have been useless, should it be shown that it would be a parallel case to build a ship of 200 tons burthen, when there was no probability of ever obtaining a cargo of half the weight.

Further, I may extend these preliminary remarks by observing, that the object which I presume you to have in view is, (after paying a due regard to to the accommodation and convenience of the public,) to carry out your measure in such a manner as shall be most conducive to the interests of those who have invested their property in it. That this should be your object there can be no doubt, and I wish to place it here as *the desideratum*, because it is one thing to design that which shall be pleasing in outline, and grand in dimensions, and it is altogether another thing to design that which, under all the circumstances, shall best answer the end in view; one of those ends being to obtain a return for the capital invested.

I am desirous that it should not be thought that I am here pre-judging the question. To all questions there are conditions, and I only wish it to be clearly understood what are the conditions of the question, which, as I understand it, this report professes to consider. And they may be repeated, that in carrying out the measure, there is to be *the fullest regard to the wants and conveniences of the public*; but also a constant regard to the prospects and expectations of the shareholders.

Now, it will not be difficult to show, that the legitimate interests of these two parties are one.

The profits of a railway are determined by the ratio of the proceeds to the cost; if the latter be greatly increased, it becomes almost imperative on the proprietary to increase the former, either by curtailing the accommodation, or by increasing the charge to the public. The public, therefore, is interested as much in the economy of railroads, as in the economy of manufactures; in the one case, if it be in fabrics, it will cause a reduction of the price per yard; in the other case it will cause a reduction in the rate per mile. And if the public, in the extended sense of the word, is to be benefited by economy being exercised in the construction of a railway, the public, in a more limited sense of the word, or the more immediate district through which the line passes, will derive still greater advantage.

Suppose, for instance, that the problem to be solved was, to give the greatest impetus to the trade, and the greatest advantage to the town of Bristol. The way to solve this problem, I think, would be, to connect it with the metropolis by a road on which parties could be carried for the smallest sum, and at a velocity not inferior to that at which they can be carried in any other direction. Now the cost at which a party can be carried will be as the interest on the *capital expended* added to the cost of working the road.

For instance, call the gross revenue of a road paying 10 per cent., 100; and call the cost of working 50 per cent.; 50 will then be left to pay 10 per cent. on a capital of 500; double the capital, and it reduces the profit to 5 per cent.

The capital ought not to be doubled, advisedly, therefore, unless one of these two things is to be accomplished by it; either that the cost of working be reduced to nothing, or that the gross proceeds to be doubled. Should the capital be increased without effecting any material reduction in the cost of working, the consequence will be, that, to increase the proceeds, the rates must be raised; and this may or may not be effectual; for an increase of charge beyond a certain limit will not increase the proceeds. If it should not be effectual, the shareholders will suffer. If it should be effectual, the public will suffer, by having to pay the higher rates.

If, supposing in the case of a railway only partially constructed, it should turn out that the traffic had been as much under-rated as the cost of the line had been increased, and that still a profit of ten per cent. would accrue, yet it proves only this, that though in the one case, by good fortune, a profit of 10 per cent. will be obtained, in the other case a profit of 20 per cent. would have been secured.

I would not apply this species of illustration to cases where the cost is increased of *necessity*; I would only apply it to cases where the increased expenditure is for some *specific object*; such as the attainment of much flatter gradients, or of very high velocities, or of much greater dimensions; which may or may not be desirable, according to the result when tried by this rule.

Now supposing this species of test be applied to one great object which you appear to have in view—the reduction of a great portion of your line to a practical level, for the ostensible purpose of obtaining higher velocities, or diminished resistance.

Between your maximum parliamentary gradient, which was 1 in 528, or 10 feet per mile, and your present proposed gradient, which is 1 in 1320, or only 4 feet in a mile, the question stands thus.

Calling friction, resistance from the atmosphere, &c., 10lbs. per ton, and adding gravity, the resistance on 1 in 528 will be 14. 2lbs. per ton, on 1 in 1320 it will be 11 7lbs. per ton, making a diminution of resistance, when ascending, of 17 per cent. Now, supposing your railway was one inclination throughout between the extreme termini A and B; in rising from A to B the increased resistance of 17 per cent. would be felt, and a corresponding increase of steam would have to be expended; but in descending from B to A there would be a diminished resistance in the same proportion, and a smaller quantity of steam would be required; and in such a case, as it regards *cost* of working, there would be very little advantage in one gradient over the other. The maximum load that an engine could draw on an incline of 1 in 528, would be less than on 1 in 1320; but on an incline of 1 in 528 all average loads could be taken.

On an incline of 1 in 528 also, to carry *the same load*, an engine would have to be a trifle heavier than on 1 in 1320; but on 1 in 528, to carry full average loads, an engine could be made of as light weight as they ever are, or perhaps can be made, consistent with the requisite strength.

If, instead of having one inclination, the line consisted of a series of inclinations greatly undulating, the advantages of the flatter line would approach nearer to the 17 per cent.; not but that it would still follow, that in going up the steeper gradients there would be increased resistance, and in going down there would be diminished resistance in equal proportion; yet in practice it has been found, that unless the inclines be of very great length, advantage cannot be taken of the diminished resistance in going down, as regards *steam*; for though it is not wanted to an equal extent, yet a great portion is wasted by blowing off at the safety valve.

But your line corresponds to neither the latter nor the former of these cases; it is neither composed entirely of one plane, nor of a series of planes *greatly undulating*; but in result it will approach nearer to the former case than the latter; for it may be said to be composed of two great planes, one rising up to the summit, the other descending from it—one upwards of 70 miles in length, the other upwards of 40, and dividing your line at the summit into two parts; it would then be analogous to the former case, in which it appears that practically, and as regards cost of working, there would be no very material difference between the inclination of 1 in 528, and of 1 in 1320, *when so circumstanced*. If in your line, therefore, the advantage of one gradient over the other be put at 8.5 per cent., it will, in my opinion, be the *full* equivalent.

Now, if the whole cost of working a railway was expended on locomotive power, by reducing the gradient from 1 in 528, to 1 in 1320, a saving of 8.5 per cent. would be effected, and therefore an increase of 8. 5 per cent. to the capital to obtain it would not be expended uselessly.

But the expense of working railways does not consist entirely of the cost of locomotive power. There are other expences that remain constant, whatever saving be effected in the locomotive department; and this fact should be kept constantly in view during the remainder of this report.

Taking the Liverpool and Manchester Railway as a standard, it will there be seen that the cost of power does not form one-third of their half-yearly expenses. It is upon this item only, therefore, that an alteration of the gradients of the nature I have been describing would effect a saving of 8.5 per cent.; and 8.5 per cent. upon one-third of the annual expenses will be only 2.8 per cent. on the whole of the annual expenses, and therefore a company would do wrong in increasing their capital more than 2.8 per cent. to effect such an alteration.

But the small saving to be obtained in many cases by reducing gradients below a certain inclination may be proved by an appeal to actual practice; not experiment only, but the every-day results of lines in operation, which is far better, for it is upon the every-day business that the saving must be effected, if it is to be.

Contrasting your line with one which opened about the same time, which also has continuous bearings, upon which an equal velocity has been maintained, and which, as will appear from the statement below, has very different gradients, it will be seen that in a case like yours I have put the advantage of a gradient of 1 in 1320 over 1 in 528, high enough.

The following are the results of Four Weeks' Traffic on each of these Lines, ending the 13th of September.

GREAT WESTERN RAILWAY.

Average number of trains per day	14
On Sundays	12
Times of running	8, 9, 10, 12, 4, 5, 6, 7
Average number of carriages per train	6. 5
Average number of passengers per train	111
	Tons. Cwt.
Average weight per train	40 5
	lbs.
Average consumption of coke per mile	51. 00
Average consumption of coke per ton per mile	1. 26
Average consumption of coke per passenger per mile	0. 45
Length of trip	22½ miles.

Average time, 55 minutes, with two stoppages.

MANCHESTER AND BOLTON RAILWAY.

Average number of trains per day	20
On Sundays	4
Times of running	7, 8, 9, 10, 12, 2½, 4, 5, 6, 7
Average number of carriages per train	6
Average number of passengers per train	72
	Tons. Cwt.
Average weight per train	24 1
	lbs.
Average consumption of coke per mile	27. 00
Average consumption of coke per ton per mile	1. 16
Average consumption of coke per passenger per mile	0. 36
Length of trip	10 miles.
Average time of making it, without stoppages	27 minutes.

Average time, 35 minutes, with 5 stoppages.

From the foregoing statement it would appear that the consumption of coke is considerably less on the line with steep gradients. But the average weight per train is in each case exclusive of the engine and tender.

The average weight of engine and tender, in working order, on the Great Western Railway, will be 27 tons.

On the Manchester and Bolton Railway the engine and tender, in working order, weigh 16 tons 4 cwt.

Adding these to the respective trains, *the average weight* of the Great Western train, including engine and tender, will be 67 *tons 5 cwt.*

The average weight of the Manchester and Bolton train, including engine and tender, is 40 *tons 5 cwt.* And

Consumption of coke per ton per mile on the Great Western, including weight of engine and tender, is 0.75lbs.	Consumption of coke per ton per mile on Manchester and Bolton, including weight of engine and tender, is 0.67lbs.

And on the Leeds and Selby Railway, with the following gradients, the results of a month's working, ending the 13th of September, are as under:—

GRADIENTS.

1½	miles	rises	1	in	210
1	,,	,,	1	,,	176
2	,,	,,	1	,,	152
3	,,		level		
3	,,	falls	1	,,	135
3	,,	,,	1	,,	152
6¼	,,		level		

Average number of trains per day, 7. 2 on Sundays.

One train extra on two market days per week.

Average number of passengers per train	57
Average weight per train, exclusive of engine and tender	32 tons 5 cwt.
	lbs.
Average consumption of coke per mile	36.00
Average consumption of coke per ton per mile	1.1
Average consumption of coke per passenger per mile	0.63
Length of trip	20 miles.

Average time 1 hour 7 minutes, with 4 stoppages.

The next subject for consideration is the increase of gauge. In examining this question, it will be necessary to put aside useless and erroneous objections; for the enquiry is one on which I am not only anxious to arrive at a proper conclusion myself, but I am desirous of enabling others to do so also; and throughout this report I shall rather aim at developing the process by which the opinions it contains are arrived at, even at the risk of being tedious, and aware though I am, that this will be laying it more peculiarly open to any who should be disposed to cavil at it; yet, on such a subject, it is better that it should partake more of the nature of demonstration than of mere assertion.

It may be observed here, that much that is absurd has been applied to the question of gauge: some have looked for advantages so great as would have left them little less than magical; they seem almost to have expected that on *such a gauge* the carriages would run of themselves. Others, on the contrary, seem almost to have expected that on such a gauge carriages could never be made to run at all. It has been applauded to the skies as being wonderful; it has been decried, and cried down, as being little less than nonsensical. Now, it is neither the one nor the other of these; it is simply a railroad of greater dimensions than those hitherto constructed, and the only question is, is such an increase of dimensions judicious or not? And the next question will be, if injudicious, considering the amount in money to which you are committed to it, is it better for you to proceed or to make the alteration?

In the first place it may be stated, for there can be no doubt about it, that just as good a road can be made 7 feet wide as 5 feet wide: it is simply a question of cost. There are some, no doubt, who have connected the effect of the malformation of your road in the first instance, with the width of ways, but of course erroneously so.

In the next place, in determining on the question of gauge, it should be considered quite independently of anything that may have been done upon your railway, which is not absolutely consequent on the increase of gauge; and I shall class among the non-essentials the peculiar mode of laying with piles, engines of 16 tons weight, and tunnels of 30 feet diameter.

It may be premised that determining the question of gauge in this country, is a very different question from determining it with regard to countries where the railway system is scarcely introduced. In England, what may be termed the great trunk, connecting the north with the south, has already been formed, or is in progress. Under the superintendence of men who were earliest connected with the Liverpool and Manchester Railway, and with railways even prior to that, it has been constructed on a gauge of 4 feet 8½ inches. They had more experience than others in railway matters; and their continuing the same dimensions as to width of way proves that they had found no occasion for altering it. Moreover, it is indisputably true, that they who have had the most experience, and who have been brought most into contact with the working of railways, see the least occasion for an alteration as to width, and are the most satisfied with the present gauge.

In addition to this main trunk, another line crossing it right angles, and of which the Liverpool and Manchester, and the Leeds and Selby Railways form a part, and which will connect the eastern with the western seas, is already constructed, or in progress, to a similar gauge: and other lines of great extent, some of them surrounding and piercing into the district into which your Railway goes, are also formed, or are rapidly forming to the 4 feet 8½ inch gauge.

And it will not be too much perhaps to say, that three-fourths of England is already being traversed by railways to the narrower gauge.

It follows, then, that any company deviating from this gauge will be isolating themselves to a certain extent; if not as regards their main line, yet as regards their branches; if not as regards their direct traffic, yet certainly as regards their collateral traffic.

But in the present early stage of railway traffic, it yet remains to be seen whether or not it may not become a great evil, for a main line to be thus isolated and rendered impossible of connection with the great lines in its neighbourhood; that it will be an evil in this sense as it regards the branch lines, there can be little doubt; for they or some of them, in course of time, will of necessity run into the neighbourhood of other lines of different gauge; but with these, however vital the connection may be, all connection will be impossible.

In this point of view only, it has become a serious matter for any company in this country to make their line to differ as to dimensions from the majority of lines around them. It is to a certain extent as if a canal company in a country of canals should construct a new navigation so, and with locks of such a character, as would totally shut out the boats of all the canals that surrounded it.

Still it is possible that there might be, coupled with the deviation, improvements of such a nature as would counterbalance the inconvenience, as would even compensate the loss. They might consist of arrangements that would effect a *great and important saving in time and money*, and in a better conservation of the property to be conveyed. and it will be necessary to enquire if such will be the result of the deviation in your case as to the width of way.

If the 7 feet gauge is to effect a saving in money, it must be in one of two ways; either by calling for less capital in the first instance, or by reducing the cost of working afterwards. The first of these it cannot do. On the contrary, the capital will be increasd certainly: to how great an extent it would be impossible for me without more time for calculation to say. But contracting the dimensions to the smallest limit; two ways of 7 feet must of necessity require a greater width than two ways of 4 feet 8½ inches. I should say, to make a line equally as convenient, this increase of width would amount to 4 feet; for the width between the ways is not to be governed entirely by the maximum width assigned to the load. A certain width is found convenient for repairs and other purposes; and too great a proximity of the ways is dangerous; as by it an accident occrring on one line may be productive of disastrous consequences on the other, as I have seen. And the width outside the ways will also be nearly a fixed quantity whatever be the gauge; for a certain width is requisite for safety, and for allowing proper consolidation to the outer rail on the embankments, and to give room for drainage in the cuttings; and, therefore, the width of the road generally, to make as convenient a road, would have to be increased by the extra width given to the ways. And besides this increase of general dimensions as to earth work and land, the locomotives would of necessity have to be heavier (I do not say to an equal extent to those you now have), and they would therefore be more costly to some extent. The permanent road will also cost more of the larger dimensions than if of the smaller; for it avails nothing to compare a light rail on the large gauge, with a heavier rail on the smaller gauge; such comparisons must be made when other things are the same, or they amount to nothing.

If then the capital will of necessity be increased, the next enquiry is, will the cost of working be diminished? The cost of working will depend on the first cost of the engines; for though, in the first instance, they may be charged to capital, afterwards they will have to be charged to current expences. It will also depend on the repairs of the engines, the consumption of coke, and the maintenance of way; and on other matters which are in nowise connected with the gauge.

As it regards the cost of the engines, it will be greater on the wide gauge; as it respects the repairs of the engines, should it prove in favour of the wide gauge, it can only be in a small degree. For the repairs of locomotives on lines where passengers are carried at great velocities, have been found to be incurred chiefly on the wheels and axles, tubes, and fire boxes, which cannot be affected by the gauge, excepting that if the wheels and axles be made larger, the repairs will be increased. And, at all events, the common repairs of a larger machine, necessarily so in consequence of the larger way, but not necessarily so in consequence of any greater traffic, it is probable, will counterbalance any saving that might be effected in the repairs of the smaller gearing, in consequence of having more room to arrange it. Besides. a great portion of the repairs of locomotives is not for common wear and tear, but is on account of accidents. And in proportion as the machine is made larger and more expensive, so will the cost of repairs consequent on accidents be increased.

The maintenance of way will of course be *fully* as great on a wider way, and with heavier engines, as on a narrower way, with lighter engines; for perhaps it would not be advancing too much to say, that the engines and tenders do more harm to the superstructure of railways than all the rest of the traffic put together; excepting perhaps loads of long timber.

And lastly, if the consumption of coke is to be reduced on the wider gauge, it can only be by the friction being diminished, or by what has been called the mechanical advantage of large wheels.

It would have been highly desirable, if before using this as an argument, the Irish commissioners had clearly determined that there was an advantage in larger wheels. For there are some experiments and several reasons for doubting that any such advantage will be derived from increasing the size of wheel. As it regards the friction of attrition, or that caused by the rubbing of the axles, it may be supposed to remain constant, however the wheel be enlarged; if it be allowed that with an enlarged diameter of wheel, and especially when attached to a longer axle, there must be a corresponding enlargement of journal; and in practice I think this would be the case. And as regards the friction of rolling, it is not likely to be diminished by increasing the size of the wheel, for the rolling friction on rails is very different from the rolling friction on common roads, where obstacles are met with that have to be surmounted by raising the vehicle over them. Small wheels on turnpike roads have been found to create much more resistance. But on a railway, unless the wheels be very small, the obstacles to motion from causes of this nature must be nearly imperceptible. And there is another species of rolling friction, caused by the grinding of the flanges of the wheels against the rails, which will be more felt in large wheels than in small wheels, and especially round curves.

But to arrive at something more definite on this subject, I will give the result of some experiments made on your line on the 20th September.

A large train, consisting of nine carriages, one six-wheeled waggon, and eleven trucks, laden with iron and stone, was got into motion up and down a long and perfectly straight inclination of 4 feet per mile. The experiment was first made upon the whole train, which gave a result of 6.22lbs. per ton friction.

The experiment was made so as to ascertain the friction of the trucks and the carriages separately, one truck only being left attached to the carriages, and the result obtained was a friction of 6.5lbs. per ton for the trucks and waggons, which weighed together 79 tons 8 cwt.; and a friction of 8.15lbs. per ton on the carriages and one truck alone, which weighed in the aggregate 74 tons 12 cwt.

On the 26th September I took six wagons on the Manchester and Bolton Railway, each laden with 3½ tons of iron, and experimented in the same way upon them, by getting them into motion, and noting the velocity and the distance run, from which the friction was determined to be 6.3lbs. per ton. The plane on which this experiment was made was terminated at each end by curves, one of 111 chains radius, the other of 67 chains radius. In the experiment up the plane the distance run was 2950 feet, the wagons having run 330 feet into the curve of 111 chains radius before they stopped. In the experiment down the plane the distance run was 3825 feet, 1980 feet of which was in the curve of 72 chains radius in which the wagons stopped. The same train of six wagons was then brought to an inclination where gravity alone was sufficient to get it into motion. This portion of the line had previously been divided by stakes into lengths of 100 feet, and the rails opposite each stake accurately levelled.

From the starting point to the ninth stake the line was straight, but at this point a curve of 42 chains radius commenced, and extended beyond the point where the wagons came to rest.

The result of this experiment, repeated twice, gave a friction of 7.32lbs. per ton; but it should also be observed that besides passing for 1300 feet along a curve of about half a mile radius, the whole distance run being about

2200 feet, the train had to pass through three shunts before coming to rest, which will probably account for the friction being higher than in the previous experiments.

This line, as well as the Great Western, has continuous bearings of wood. Though for a short distance in the curves in all the experiments on the Manchester and Bolton Railway, the motion was continued on continuous bearings of stone. The Manchester and Bolton line has a heavier rail of (53lbs. per yard). And in the Great Western experiments, three of the carriages and one wagon had six wheels each, which have rather more friction than those of four wheels; but in such a large and heavy train, no great difference could be caused by this.

The whole of the wheels in the Great Western experiments were four feet in diameter, the journals 2 11-16 inches in diameter. In the experiments on the Manchester and Bolton Railway the wheels were of three feet diameter, and the journals of two inches diameter; and four feet : three feet : : 2 11-16 inches : 1 1-16 or two inches nearly. But supposing that neither the foregoing experiments nor reasonings are to be decisive as to the mechanical advantage of increasing the size of the wheels, and I do not mean to say that they are, for to determine the question clearly the experiments should perhaps be made on the same road; yet still as a general question there will be several drawbacks on the theoretical advantage of the larger wheel, such as the greater resistance on curves with the wider way; more rubbing of the flanges against the rails, not only in consequence of the larger wheel, but of the greater breadth of way; for I think it is probable that friction would be reduced to a minimum by concentrating the whole momentum of a train on one rail, and that friction will be increased in some degree, as the distance between the wheels, or as the width of way is enlarged.

The next enquiry respecting the gauge is as to the matter of safety. If the gauge is to be altered on this account, it should only be because of a want of safety in the present gauge. If A be safe, there cannot be the smallest advantage in making B safer.

Now the question is, is the narrower gauge safe? It might have been reasoned *a priori* that the width between the railway wheels being equal to those of turnpike-road carriages; and from the very great weight of railway wheels and the under carriages, the centre of gravity being in all cases much lower on a railway coach than on a stage coach; and the railway itself being infinitely more smooth and perfect than the common road; that though the velocities are much greater, yet still there is no danger of overturning. And the fact is, I have never heard of a case of overturning, or of any accident that I should attribute to the narrowness of base, occurring. And from what experience I have had on Railways, I believe it would be a most difficult matter to overturn the carriages upon them, with the present gauge, even if the object was purposely to do so, and an experiment should be made for the purpose. But having heard it urged that there was greater safety on the wider base, which may be granted, but which amounts to little if there is quite enough of safety on the narrower base; and being unable to call to mind a single instance of an accident or of an overturning in consequence of a narrower base, I addressed a letter to Mr. Booth, the treasurer of the Liverpool and Manchester Railway, on the subject, to know if he had ever known an accident that could be attributed to the narrowness of base; I also wrote a similar letter to Mr. Smith, engineer on the Leeds and Selby Railway, and I received the following replies:—

"Liverpool and Manchester Railway,
"Lime Street Station, 21st Sept., 1838.

"Sir,—I have to acknowledge the favour of your communication of the 19th, enquiring whether or not, in my experience, there is any want of safety in the present gauge, 4 feet 8½ inches as to the chance of overturning; and also if I have known any case of overturning in consequence of narrowness of base, or are aware of any accidents having occurred, which I would ascribe to the narrowness of the 4 feet 8½ inches, base.

"In reply, I beg leave to inform you that in my opinion there is not any want of safety in the 4 feet 8½ inch gauge, and I am not aware of any accidents having occurred, which I should ascribe to the 4 feet 8½ inch gauge. The only case of overturning which I recollect occurred some years ago, when, owing to the breaking of an axle, the engine (which had only four wheels) quitted the rails, and drew several of the carriages over the embankment, near Bury-lane.

"Whether in such a case a broader base would have prevented the carriages overturning, I will not pretend to say; it might depend on the relative height of the carriages and other circumstances. "I am, Sir, &c.,
(Signed) "Henry Booth."
"John Hawkshaw, Esq."

"Leeds, 21st Sept., 1838.

"Dear Sir,—In reply to yours of the 19th inst., we have had but one accident (during the experience of four years) that was not occasioned either by tongues being wrong or some obstacle in the way The one excepted, was caused by the repairers raising some wood sleepers too much at once on a new made embankment. I do not consider there is any want of safety in the gauge, (4 feet 8½ inches) nor do I know of any accident or overturning which can be attributed to that guage.

"I am, dear Sir, yours, &c.,
(Signed) "Geo. Smith, R.E.,
"John Hawkshaw, Esq." "Leeds and Selby Railway."

Besides, there is no difficulty in lowering the centre of gravity on the present gauge very considerably, were such a thing desirable or called for. For by making the coaches omnibus fashion, the passengers in each coach could be made to sit a foot lower than at present. That this is not done goes a great way to prove that it is unnecessary. Or by keeping the centre of gravity as it is, it is quite easy and practicable with the present gauge to increase the size of the wheels from three feet to three feet six inches, or larger, if any thing was to be gained by it.

Having gone into the question of gauge abstractedly from what has been done upon your line in connection with it, and debiting the system of a 7 feet rail with such an increase of cost only as appears to me to be absolutely consequent on its adoption, I feel compelled to come to the conclusion, that there are no advantages to be obtained by adopting it, at all commensurate with the evils that will be consequent on the deviation; and for the reasons which follow, it is not desirable, in my opinion, to proceed with it, unless you were already committed to it in a pecuniary sense, to an amount that will outweigh all the objections to it, but which will be seen hereafter.

The additional reasons for not proceeding with it are these;—first, considering the great cost, and the comparatively small profits of railway lines generally on the smallest dimensions, and the great difficulty there is, and the corresponding increase of outlay that is incurred, in obtaining curves of sufficiently large radius to be workable at the present narrower gauge; I cannot conceive that there is a single practical man in England who could recommend the 7 feet gauge, as general system for this country.

If unfit as a general system for the whole country, it will be unfit as a partial system for a portion of it; unless that system is of necessity to be very much confined; its ramifications into other districts impossible from natural barriers, such as seas, or lakes; and the nature of the country, such as to undulations, that the cost of obtaining curves of larger radius will be trifling.

Even admitting that the latter condition is true of your line, and that from its general flatness curves can easily be obtained of large radius, yet this cannot be predicated of the whole of the branches and extensions to which you will have to look for collateral and extended traffic. And even if it could, still the system is unquestionably more expensive to some degree, and though you with your large traffic might not be totally crushed by it, it has yet to be seen what the effect will be on the smaller and less favourable lines; which, to get into yours, will be compelled to adopt similar dimensions, and involving of course similar expenses. At the same time, the prosperity of your line will be affected in no small degree by the prosperity of the tributaries to it; and in fact, a probable result of doing things on such a great scale will be, to drive traffic which otherwise would come upon you, in some other direction. For in railway lines generally, in the same country, there will come to be a mutual dependance one upon another. And surely it must be rather an untenable doctrine to hold, that the gauge of each line is to be determined only by reference to its curves and gradients, for by such a rule it would follow that no two lines could be alike.

Finally, it may be said of railway lines, that they will not bear any additional expense. It may perhaps be said of every railway formed in this kingdom, that if the company had to begin again, their object would be to economise, and to diminish their first outlay, not to increase it; or if there be a railway company, and such are rare cases, that has already devoted its attention to the utmost in keeping down the expenditure in the first instance—that railway company would not do otherwise if it had to begin again; and that railway company will feel that for the course that has been pursued, there is every cause for congratulation.

I could not advise you to take the London and Birmingham as your model, and feel satisfied if you exceed them as to cost in only a few particulars; their line was necessarily through a country very different, and far more expensive than yours; and their line is in a position in which, if a great expenditure is to be repaid anywhere in this country, it will be to them. For I cannot conceive that your line, or indeed any other line that I am acquainted with, can expect an equal amount of thorough traffic; for into their line a great portion of the north of England, and a still larger portion of Scotland, besides the great manufacturing and commercial districts of Birmingham, Manchester, and Liverpool, must of necessity converge before arriving at the Metropolis.

Still, though I do not see that the aggregate of your traffic can ever be expected to equal that of the London and Birmingham; yet, considering the much more favourable country through which your railway passes, and that the traffic upon it will be unquestionably very large, I think your line presented equally as good features for investment, and perhaps may do so still; it will depend, in my view, upon the course you pursue.

That course, as far as my opinion goes, is not to go forward on your present system. Knowing that railways hitherto, and on the smaller scale, have been found greatly expensive, so much so as scarcely in any case to leave an ample dividend, when the great risk of such investments is considered, I cannot advise you to proceed on a plan which, in all human probability, will materially diminish that dividend.

It cannot be necessary for the attainment of safety, when in the present gauge there is no danger.

It cannot be required for the attainment of high velocities, because on the narower gauge velocities can be attained with perfect safety, greater than could be maintained by any railway company in England perhaps, without absolute ruin to themselves in a pecuniary sense.

The Liverpool and Manchester Railway, by increasing their speed from 20 to 26 miles per hour, have increased their locomotive expenses about 15 per cent. Much higher velocities than this are attained, and with perfect safety, on the narrower gauge; but there is no company that could bear the increased expense of maintaining such velocities constantly, or if there be, it will be found to be that company which has expended the least in the first instance. For example: the Grand Junction would feel the effects of increased expenditure to maintain a very high velocity, less than would the London and Birmingham; not that their gradients are better, they are worse; but simply because their first outlay is much less, and therefore their annual expenses might be much increased, and still leave as large a revenue: in short, for very much the same reason that 20s. for carrying a passenger 97½ miles on their line, will probably pay them quite as well as 30s. will pay the London and Birmingham Company for carrying a passenger 111 miles on their line.

But in advising you not to proceed in constructing your line on the larger scale, it is necessary to take a review of the consequences.

You are, to a certain extent, committed to it in a pecuniary sense. This amount can be ascertained and contrasted with the saving to be effected by contracting the dimensions, if there be a saving; if there be no saving as to first cost, in making the alteration, yet as I believe there would be a material saving in the expenses afterwards, and other advantages of greater magnitude still, such as the avoiding the introduction of an expensive system into districts which can ill afford it, the consequent re-action from which would be felt by our own line, I feel bound to recommend you to make the alteration.

That which will go to the *debit* of making the alteration will be as follows:—

22 Miles of road to be taken up and re-laid, the same materials being used, £1,500 per mile....		£33,000 0 0
14 Locomotives and tenders received (adapted for wide gauge) £1,980 each,	£27,720 0 0	
7 Engines and tenders, constructing, say same price........................	13,860 0 0	
42 First-class carriages at £544............	22,848 0 0	
40 Second-class carriages at £351	14,040 0 0	
118 Trucks and wagons at £106	12,508 0 0	
		90,976 0 0
		£123,976 0 0

On the rails I do not consider there would be any loss, for though I think them too light, yet they will be much less objectionable in this respect on the narrower way.

That which will go to *the credit* of making the alteration will be as follows:—

£1,000 per mile to be saved on 100 miles of permanent way yet to be laid..	£100,000 0 0
£400 each less upon 60 engines and tenders yet to be obtained to make full stock	24,000 0 0
£200 per mile less on earthwork, &c. yet to be completed, say 60 miles...	12,000 0 0
Say 20 per cent. on tunnelling yet to be done, by the narrower gauge, requiring 4 feet less width, say 2,000 yards, at £10	20,000 0 0
	£156,000 0 0

It is useless to push this enquiry further. It is clear that even considering the question as if your present stock of engines, carriages, &c. would be valueless if you alter the gauge; and contrasting this loss with the saving that would be effected by adopting the narrower gauge, supposing that in prosecuting the 7 feet gauge you were only in future to do that which is barely necessary, still, taking such a view of it, the advantage in a pecuniary sense is decidedly in favour of an alteration of the gauge.

But if the comparison were made on the supposition that in carrying out your system as to gauge, you were to continue the large dimensions you have begun with, the pecuniary advantages in favour of reducing the gauge would be very much greater.

Further, there is no necessity for considering all your present-stock of engines and carriages as valueless; for supposing you should decide upon altering the gauge, it could be done as follows.

It would be necessary in the first place to curtail the dimensions of all the works yet remaining to be done, and to proceed with taking up one of the lines between London and Maidenhead and to relay it to the narrower gauge. In the mean time your present traffic in passengers could be carried on very well on one line. On the railway between Antwerp and Brussels, greater numbers are carried on a single line of way. This would of course afford employment for your present stock of engines and carriages for probably a year and a half, and would therefore go to diminish the sacrifice that ultimately would have to be made; that sacrifice would be still further diminished, by the value of such part of the carriages, trucks, and engines, as could be applied in the construction of others for the narrower gauge.

Of course the traffic would have to be transferred to the line of narrower gauge before the second seven feet way between London and Maidenhead could be taken up; it might then be relaid to the narrower gauge, and could be got ready by the time that an extended portion of your line should be prepared for opening.

Having come to a conclusion that so great an increase of guage as to 7 feet is to be avoided; the question will arise, is 4 feet 8½ inch exactly the thing? No one, perhaps, will pretend to say that it is so precisely, or that an inch or two in addition could make much difference as to cost. Of course the objections to increasing the width of way, on the score of expense, become less as the increase to be made is diminished; the *main reason* in my view for abiding by the 4 feet 8½ inch guage in this country is, that it has been greatly adopted, and that there are no very substantial grounds for altering it. I have never heard any one, whose opinion I should esteem of great value from their experience of the working of locomotives on railways, wish for more than a few inches of additional width, five or six inches at the utmost; and even as to this increase, just in proportion as the parties had had much to do with the working of the locomotives on railways, so in the same proportion did they esteem even it to be of minor importance.

Perhaps, if railways were just commencing in this country, an addition of a few inches, five or six inches at the most, might be made; but the advantage to be gained by making it now, in my opinion, would in no manner compensate the evil that will arise from a variety of gauges in the same country.

Impressed with the importance of having other opinions on this subject than my own, I addressed a letter to two of the largest manufacturers of locomotives in this country, requesting from them to know what in their opinion were the practical disadvantages of the 4 feet 8½ inches guage as affecting the manufacturer.

The opinions of both these parties in my view are peculiarly valuable, for they were not only amongst the earliest locomotive manufacturers, but have also had much more experience as to the working of their engines on railways than any other manufacturers I know; and without this latter kind of experience, manufacturers are, to a certain extent, only theorists, as to the question in hand.

Their answers are below.

"Liverpool, Sept. 29th, 1838.

"Dear Sir,—In reply to your letter of the 27th inst. referring to the question of the right guage, which at this time is so much agitated,

"I beg to state that though we do not labour absolutely under great difficulties, in consequence of the want of breadth, yet there is no doubt an addition to the present width (4 feet 8½in.) of a few inches would enable us to make a more perfect engine. The addition of 6 inches would be ample, and I consider any thing beyond that would tend to increase the difficulties beyond what we now experience, rather than otherwise.

"Yours truly,

(Signed) "Edward Bury.

"John Hawkshaw, Esq."

"London, Oct. 1, 1838.

"Mr. John Hawkshaw.

"Sir,—The extent of inconvenience we experience in the construction of locomotive engines of moderate power (say 14 inch cylinders) for a gauge of 4 feet 8½ inches, is very small indeed. In our early engines an additional width of 3 or 4 inches would have facilitated the arrangement of the working gear and eccentrics; but this has since been simplified, and our latest arrangement of those parts leaves scarcely this small increase of width to be wished for.

"The construction of engines for Russia for a six feet gauge, leads us to believe that a considerable increase of expense is attendant upon increased width; more especially if the power of the engine is considered to bear any relation to the width of the gauge. If the power or dimensions of the engine be kept the same, the additional expense consequent upon an increase of gauge will not be very considerable.

"We are, Sir, &c.,

(Signed) "Robert Stephenson & Co."

With respect to Mr. Bury, it may be observed, that if any manufacturer in England has felt inconvenience from the 4 ft. 8½ in. guage, he must have done so; for, from the peculiar construction of his engines, it is a principle with him to use inside bearings only, which necessarily leave less room for the working gear than when outside bearings are used.

BRIDGE AT MAIDENHEAD.

I have carefully inspected this bridge, and find that at the crown of the eastern arch, and for 12 or 14 feet on each side of it, there is a separation between the 1st, 2nd, and 3rd rings of whole bricks, counting from the soffit of the arch; these separations generally are about half an inch wide; and extend three or four yards each way from the crown of the arch; the dislocation appears to be less towards the interior, for on making a hole quite through the brickwork in the centre of the arch, it was found that there was a separation only between the 2nd and 3rd ring of whole bricks, but this separation was about an inch in width.

There is nothing anywhere that I could perceive like crushing of the bricks, or dislocation in direction of the thrust.

I think it probable, therefore, that if a few iron bolts were put through the arch, so as to prevent any further separation, and the crown of the arch loaded with additional weight, that the bridge might stand, and perhaps be quite strong enough for anything that ever may be required of it. But I cannot say that I should advise such an experiment to be made on such a structure, especially as putting its stability beyond all question will not be a very serious matter.

I should recommend, therefore, that from 25 to 30 feet of the crown of the eastern arch be taken out, (the precise quantity will be seen as the arch is opened), and replaced with stone, the facing of the elevation may still be of brick, so as not to destroy the appearance of the bridge. The stone will give greater weight to the crown of the arch, which I think is wanted; and I should also recommend an additional weight to be placed on the crown of the western arch; a couple of courses of 8 or 9 inch landings would do; for I find difficulty in accounting for the appearances presented, otherwise than on the supposition that the haunches of the arches have had more than their full share of load; and at all events, I am of opinion that some additional weight on the crown of both arches will be of service, and will add to the general stability of the structure.

PERMANENT WAY.

The mode adopted in laying the rails, is, I think, attempting to do that in a difficult and expensive manner, which may be done at least as well in a simpler and more economical manner.

LOCOMOTIVE POWER.

Beyond what may have been said on this subject generally in the preceding parts of this report, the length to which it has already extended forbids my saying much more. Generally, I should say, that the power of your engines should be proportioned to your loads.

Employing engines capable of drawing 200 tons to drag loads averaging 50 tons, will be very much like fastening eight horses to a post-chaise.

The great weight of locomotives is a positive evil. It is so, because they have to be carried about for nothing. It is so, because they do more harm to the road than anything else, and a railway is to be made stronger and more costly on account of them. But, to a certain extent, it is a necessary evil; but only to a certain extent. And if the weight be increased beyond this limit, it will be so much thrown away.

The weight of the engine should be determined by the average load be taken, and the nature of the gradients.

Moreover, the engines will work economically, or otherwise, in proportion as their power approximates to their loads.

The average of your passenger trains cannot be expected to be greater or heavier than on the Grand Junction Railway. Supposing them to be the same, as to weight; from your flatter gradients, engines of little more than two-thirds the power of those on the Grand Junction, and therefore of considerably less weight, would be sufficient for you to travel at equal velocities. If you wish to travel at double the velocity, of course you must have more powerful engines; but it should not be forgotten, that you can only travel at double the velocity, by pretty nearly doubling the cost.

Finally, I should say of your line, that the country is favourable, and the gradients good; naturally so, or in so far as they are dependent on the undulations of the country.

Further, with such a traffic as you may expect, and such a country, your line holds out great inducements for the investment of capital.

But the advantages of country will be lost sight of and nullified, if for the sake of a system, the cost of the road be greatly increased; and even the good gradients will be rendered of non-effect as to economy, if the speed be greatly increased; for greater speed will entail greater cost and will be tantamount to steep gradients.

And though the same results may perhaps be obtained on railways of better gradients, with more dead weight than on railways of bad gradients, yet this seems to be merely bringing down the good line to the standard of the bad.

I am, Gentlemen, your very obedient servant,

(Signed) JOHN HAWKSHAW.

Manchester, 4th October, 1838.

REPORT OF I. K. BRUNEL, Esq.

TO THE DIRECTORS OF THE GREAT WESTERN RAILWAY COMPANY.

Gentlemen,—In compliance with your request, I beg to submit to you the following observations upon the only report which you have laid before me; that expected from Mr. Nicholas Wood not having yet arrived.

Knowing that I should be called upon to express an opinion upon the subject of these two reports, and that the time allowed me would necessarily be very short, I had proposed to class, as far as possible, their contents under two heads,—viz., first, *facts*, including under this head the statement of actual results ascertained upon the Great Western or other lines, and general principles, or rules, laid down and assumed as axioms, whether of mechanics, mathematics, or of the practical working or economy of railways; and, secondly, of the *arguments* founded upon these facts or axioms, including the inferences drawn from them and the opinions expressed.

I proposed, in the next place, to consider how far the former were applicable to the case, and, what is of great importance, how far they constituted *all* the facts that it was necessary to state for the purpose of arriving at a fair conclusion. I intended then to have discussed the correctness of the latter, and thus to have arrived, by a clear and satisfactory process, at the object I had in view, which was, to give my opinions and my views on the same subject as that of the reports; to compare them with those of the writers; to show wherein I agreed with them and where I differed, together with the reasons and grounds for the differences between us.

This would, I think, have laid before you a business-like view of the case, and such as I should have wished to have submitted to you. I regret that the peculiar nature of the only report yet received puts it out of my power to pursue this course; for having carefully read it, I found, that by confining myself to the division or classification which I had proposed, I should have passed over in silence a very great portion of its contents, unless I formed a third division, including neither such facts or arguments as I have described, but consisting of general remarks and hypothetical cases, and even the opinions of others founded upon hypothetical cases. It is true, there are many remarks and comparisons made which are not applied directly to the Great Western railway, nor are they in terms stated to be strictly relevant; neither are the cases hypothetically put afterwards proved to have any practical existence, or made to throw light upon any of the existing circumstances of the railway; but being interwoven with a report specially made, upon the Great Western railway, they are calculated, however inadvertently, to mislead, unless their irrelevancy is pointed out.

I regret very much the necessity of considering these portions of the report, as it involves the tedious process of referring almost to each page, and of frequently entering into long explanations to remove a misapprehension, produced, perhaps, only by a single word; but no alternative is left to me. The utmost extent to which I can venture to depart from the line pursued by the report which I have before me, will be to consider the subject, in the first place, in what appears to me the engineering and business-like view, and then, subsequently and separately, to consider the particular manner in which the writer has treated the question.

The report, after a few preliminary remarks, is divided under the the following heads, and they are considered in the order stated,—namely, the objects to be attained in the construction of a railway, or what are very properly called, "the conditions of the question;" the comparative advantages of good gradients; the width of gauge; Maidenhead bridge; the construction of the permanent way; and the locomotive power. I shall now consider the subjects in the same order, and, for the sake of perfect accuracy, refer to the pages and paragraphs of the printed copy before me. As the opinions expressed, and the conclusion arrived at, in this report, are generally, if not wholly, diametrically opposed to those which I am known to entertain, and which I am now quite prepared to support, it is but just to state, at the outset, that I differ altogether from the general principles laid down, which appear to me to be unsound, and, indeed, to be incorrectly and insufficiently expressed; and I must say, that I consider the reasoning fallacious and defective, and that many of the calculations are incorrect or erroneous from the omission of quantities or conditions which must affect the results.

In the report (p. 46), the conditions of the question are stated to be, that, "there is to be the fullest regard to the wants and conveniences of the public, but also a constant regard to the prospects and expectations of the shareholders," in which I concur. But the observations which follow I entirely dissent from, for which I will shortly state my reasons. It is said that the "profits of a railway are determined by the ratio of the proceeds to the cost; if the latter be greatly increased, it becomes almost imperative on the propietary to increase the former, either by curtailing the accommodation or by increasing the charge to the public."

In noticing this paragraph, I wish to premise that I deprecate, as much as any one, all *useless* expenditure, every increase of the capital of any company not justified by a fair probability of return, either by economy in the management or in the maintenance of the work, or by increase in the income to be derived from traffic:—and I must distinctly say, that no departure from a sound and wise economy would ever receive my sanction. Having said this, I now, in answer to the observation I have quoted, would beg to remark, that at whatever cost a railway may have been constructed, the only way to increase its proceeds is the same in all cases: you can only induce the public to travil upon a railway, by holding out better accommodation or lower charges, or both, than they can find elsewhere,—by, in fact, *reversing* the means recommended—by increasing the accommodation or curtailing the charges. Expedition, comfort, and cheapness, are the temptations to railroad travelling, and, according to the degree in which they exist are made manifest, will the public use the railway. The object is, to get the largest income by these means,—the income must depend upon the facilities afforded. Let the railroad cost what it may, it is by no such process as that recommended that "proceeds" can be increased, but by one just the reverse, which is and must be the common object of all companies,—viz., to obtain the maximum ef traffic and income: and no curtailing of the accommodation, no increase of charge to the public, can do this.

It is stated in the succeeding paragraph (p. 48), that "the cost at which a party can be conveyed will be as the interest on the capital expended, added to the cost of working the road;" and inversely, as the number carried, should have been added. But this important condition, which totally alters the arithmetical result of the cost of transport, is altogether omitted. Again, in what immediately follows it is said, that if "capital be increased without effecting any material reduction in the cost of working, the consequence will be, that to increase proceeds the rates must be raised. May not the number of passengers and the traffic be increased by such additional outlay, and thereby the proceeds also?

Such are the principles ef railway economy which are laid down. I might perhaps avoid the necessity of further discussing them, by dropping them as suddenly and as completely as they are dropped after this last-quoted paragraph in the report, but as an impression is produced (although no direct inference is drawn) by their assertion, I will examine what I conceive to be the views of the writer on their intrinsic merits.

The theory of trade advanced in this part of the report may be stated thus; that the only mode of increasing the gross profits is to increase the profit upon each article by raising the price or by reducing the original outlay. No doubt this is one method, if it can be effected; but I believe it would be difficult to point out any one great branch of trade which has thriven in this country by such a course. But, on the contrary, in every branch of manufacture, each year the necessary machinery and plant become more costly, the price of the articles manufactured is reduced, and the profits upon any given quantity diminished; but the gross profits are at the same time maintained and increased by the great increase of consumption consequent upon diminished prices or improved quality.

In railways, the same principle applies, and, if possible, in a still greater degree; yet in the report it is assumed throughout that the consumption, or, in the case of railways, the number of passengers and the traffic, is a constant quantity which, on the one hand, is secured to the railway whatever may be its comparative inconveniences or defects, and, on the other hand, cannot be increased by any additional accommodation, or by any other inducement held out to the public.

It is upon these views that all the arguments adduced in favour of reduction of first cost are founded in this report; in no single instance is any allusion made to the possibility of increasing the number of passengers by improving the means of conveyance. The great argument of all the promoters of railways, the striking results of experience in every railway—namely, the increased number of travellers consequent upon the increased facilities of conveyance, is totally lost sight of.

It is unnecessary to dwell any longer on this point, more particularly as I shall have occasion to refer to it hereafter; but it appears to me clear that no conclusion founded upon this reasoning can be safely relied upon.

The next question—namely, the effect or value of gradients, is one so susceptible of calculation, that it might be supposed to be a point upon which no great difference of opinion could exist; and when the calculations are exactly made, and the simple results clearly stated, no difference will be found to exist.

In the comparison between gradients of 10 feet per mile and 4 feet per mile (p. 49), in which a diminution of resistance when ascending the latter, as compared with the former, of 17 per cent. is admitted, data are assumed different from those generally given by the best authorities on the subject, and conditions most essential to an accurate comparison are omitted. Ten lbs. per ton are assumed as the resistance on a level; eight lbs. have generally been taken as nearer the truth, and, upon a railway in good order, with carriages also in good order, may safely be taken as the total resistance of a train. The effect of gravity in inclinations of 4 feet and 10 feet will be 1.7lbs., and 4.25lbs., which, with the constant of 8lbs., makes 9.7lbs., and 12.25lbs. per ton; this, or 100 to 126, gives the ratio of the resistance on the two gradients, being already 26 per cent., instead of 17. But if the maximum load that an engine can draw (of course at the regular speed of the trains) up the incline be taken, the weight of the engine and tender must be deducted, in either case, to obtain the effective load. In fast trains, such as those running on the Liverpool and Manchester line, the engine and tender will be about 30 per cent. of the gross weight, in the three cases cited by the writer at p. 8 and 9, the proportion is even greater, being two-fifths, or 40 per cent.; but I will admit even one-fourth to be the proportion, which would be allowing a fast passenger-train to weigh nett 60 tons, with an engine and tender, such as those of the Grand Junction, weighing 20 tons. From 100 and 126 is therefore to be deducted one quarter of 100, or 25, leaving 75 and 101, which are as 100 to 134, being an excess of 34 per cent. instead of 17 in the nett load which the same engine will be capable of drawing at the same velocity up the incline of 4 feet over that which it would draw on an incline of 10 feet; but the writer, after making the calculation, proceeds to sink all comparison by the simple assertion, that "on an inclined plane" of 1 in 528 (10 feet per mile) all average loads "could be taken." Undoubtedly they can, but at a proportionate sacrifice of power or speed, which ought to have been added; without it the statement is incorrect, and with it I do not understand the object of the observation. The naked result of the above calculation is not altered by the omission, although certainly it may in consequence escape the recollection of the reader.

In the next paragraph the same thing is asserted in a different shape. It would have been desirable to have had explained what was meant by a "full average load." It appears to be assumed as a fixed or constant quantity for all railways, and quite independently of the gradients, or even of the power of the engines. I do not understand how any such fixed quantity can exist. Several of the present trains on the Grand Junction railway require two engines; should they increase so as to require three, it will probably be necessary to divide them; the capabilities of the line, or of the engines, will then have influenced the load. In the cases of the three different railways before referred to as quoted in the report, the average nett loads of the trains referred to are, 24 tons, 32 tons, and 40 tons respectively; and the average load in one case is therefore nearly double that in another.

Whatever may be the results on other railways, we know from experience on the Great Western, that our best engines, which are considered so unnecessarily powerful, have been barely sufficient to take the loads which, under certain arrangements of trains, we were obliged to carry, and that intermediate or half-hour trains became necessary. That many such inconvenient arrangements would have been required if the loads had practically been increased 34 per cent., with gradients of 10 feet per mile, I need not tell you who are familiar with the details of our traffic. I regret the necessity of devoting so much space to an attempt to render more clear that which appears to me to be self-evident,—namely, that a load of 134 tons cannot be carried at the same speed and with the same power as one of 100 tons, or, in other words, that the addition of a useless load of 10 or 15 tons to one of our ordinary trains would not be unimportant; but the paragraph I have referred to implies this, and there being no argument advanced in support of it which could be examined, it becomes the more necessary to take notice of it.

The particular arrangement of the gradients on the Great Western railway and their effect upon the traffic are then gone into, and at the end of the paragraph, page 49, the advantage of 17 per cent., before alluded to, is reduced one half, or 8½ per cent. How this is done I have not been able to perceive, as I find neither argument nor calculation to justify it. It is true it is very fairly given as *an opinion*; but, as there are many figures and quantities given in the course of the preceding paragraphs, the word "therefore," at the conclusion of the paragraph, would lead a cursory reader to suppose it was proved by some preceding calculation or reasoning. As some allusion is made to a supposed saving of the power in one direction which is expended in the other, and as 8½ is half of 17, it is barely possible that it is arrived at by a system of averaging the power required in the two directions; but, in the first place, no such average can be taken, the maximum power that is required in any one part of the line must be provided, and must be carried at all times, even if no power at all be required on other parts of the line; and, secondly, if the expenditure of power is to be averaged, then the increase of gradients makes *no difference* in the average power, as the decrease of power in descending is said to be equal to the increase in ascending, and therefore balances it. The fact is, that there is no ground whatever for halving the 17 per cent. (which I have shown to be 34 per cent.) *as a measure of the effective power of the same engines under the two circumstances*, and consequently none whatever for fixing it at 8½ per cent.

After this, the 8½ per cent. is reduced to 2.8 per cent., in so far as relates to the value, in money, of such reduction in locomotive power; and the assertion is made, preceded again by the word "therefore," that a company would do wrong to increase the original capital more than 2.8 per cent., to effect a saving of 2·8 per cent. in the annual expenditure. Can it possibly be meant that if the capital be a certain sum, say 1000*l.*, and the annual expenditure 150*l.*, leaving 150*l.* of nett profit, that a company would do wrong to add 2½ per cent., or 25*l.*, to their original outlay, unless this secures 2½ per cent. saving, or 3l. 15s. on the annual expenditure, or 15 per cent. for the money? This is evidently a great mistake, arising from the total confusion of the capital with the annual expenses, as if they were the same sum, and the apparent accuracy and proof are produced only by the repetition of the same figures in the two cases, although, in fact, there is no such identity. The way in which a man of business should proceed, would be to capitalize the annual sum likely to be saved at some given rate of interest, which in his opinion would cover all risk, and leave a profit, perhaps of 6, 8, or 10 per cent., according to circumstances, but having no reference to the particular per centage which the annual expenditure might bear to the capital; and this amount a wise man would expend, not only to increase his future profits, but also to *secure permanent advantages to the concern.*

The calculations, erroneous as I think I have shown them to be, do nevertheless, make out a case in favour of good gradients. But upon turning to a statement given of actual results upon three railways, these very calculations are annihilated. These experiments, if they prove any thing, prove an actual advantage in favour of gradients, not of 4 feet per mile, nor of 10 feet, but of very steep gradients of 30 feet per mile. The naked result gives a less expense of power on two lines, on one of which half the length consist of gradients above 26 feet per mile, and on the other, 8 miles out of 20 consist of gradients upwards of 34 feet per mile, over a line the maximum gradient of which is 4 feet per mile. No explanation is given. The question here is not one of the comparative perfection of the lines, in other respects, or of the carriages, or of the probable effects of circumstances not mentioned; it is adduced expressly as a practical measure of the value of gradients, and is left without comment or explanation, to produce its effect on the mind of the reader. As such it does appear to me, and I think must to any impartial man, that the proof is overmuch, and becomes valueless; that the results cannot be correct, and that there evidently must either be an error in the data, or there must be circumstances quite independent of the gradients which require separation; otherwise we are driven to the conclusion that *steep gradients are best.*

I have nothing before me but the results, and therefore I cannot pretend to discover all the sources of error; but I know that some of the data are such as must introduce error; for instance, the consumption of coke given as that of the Great Western railway, includes all that had been used in raising and keeping up the steam in the engines, which, in the first working of a portion of a line, and while the arrangements are not matured, is necessarily great; it includes also the coke expended in ballasting trains and experimental trips.

In fact, during the four weeks ending September 13th, which are referred to by the writer, I find that there were generally seven engines in use, and of these, two were employed upon the line, (not on the passenger traffic,) and one was kept with the steam up, as a spare engine. How can the results of consumption per ton per mile be correct with such sources of error?

I must beg, however, to keep your attention to the 34 per cent. at which I have arrived, as the advantage, in actual *effective power*, of a gradient of 4 feet over one of 10 feet.

The gradients must ultimately govern the power of your engines, their speed, (at all events in one direction,) the size of each of your trains, and consequently their number; and it must always be remembered, that their operation is a *permanent* one, which nothing can remove or even alter, and the effect of which nothing can diminish. On the contrary, I am prepared to show, that the value of low gradients will, in all probability, be much increased.

I have assumed 8 lbs. per ton as the resistance of a train; but as the greatest part of this resistance depends upon the workmanship, the form, and the mechanical construction of the carriages, and other causes, and may be reduced by various contrivances already known, it would be contrary to all experience to suppose that it will not be materially reduced when there is an object to be gained by its reduction.

In many experiments, with all the circumstances favourable, the resistance has been as low as 6 lbs.

In some made by Mr. Hawkshaw, on the Great Western Railway, the resistance of a train, consisting partly of trucks and partly of carriages, only gives 6.22 lbs.

It may therefore be assumed, that we have now within our reach improvements by which the resistance may be reduced to 6 lbs.

With this datum, and making the same calculations as before, we obtain 100 and 144 as the comparative loads which the same engine would take at the same speed up the two gradients of 4 feet and 10 feet per mile.

Such an increase in the capabilities of engines must be of immense importance in passenger traffic. But how undeniably important it must be, even according to the principle laid down in the report, in the conveyance of goods; in this service the maximum power of the engine *is* brought into operation, and *does* constitute the limit; and if the engine, in such case, only forms one-eighth of the gross load, the proportion will still be as 100 to 135.5.

This advantage, large as it is, is a highly probable one, and I venture to predict it as a certain one; but, confining ourselves to the results which may be obtained with the existing rails and carriages, I will consider what is the practical working of an increased useful effect of 34 per cent. by the same engine, or an increased resistance of 26 per cent. with the same load. According to the view of the writer, in page 5, of there being a fixed standard or average power of engine which will be the same in either case, the former,—namely, 34 per cent. of increased effect—would be the correct mode of considering the comparison. I will assume, however, the latter, as being least advantageous, and I will suppose the engines, although different in power, to be of the same weight. Now, the resistance in ascending and descending a plane of 4 feet per mile will be 100 and 66; with the 10 feet per mile, it will be 126 in ascending, and actually only 39 in descending.

In the case of the Great Western Railway, from London to Slough, Maidenhead, Reading, and to the point of departure to Oxford, the maximum rise is 4 feet. Had it been 10 feet, as I must infer would have been the recommendation of Mr. Hawkshaw, the resistance going and coming would have been 126 and 39. Now, of what avail would it have been, that in returning to town the resistance was small? No more passengers or carriages could be brought one way than must be conveyed the other, or, to apply one of Mr. Hawkshaw's own similes, the eight horses required to take the post-chaise out must return with it, though two might be enough. I quite agree with the opinion very strongly expressed in another part of the report, that for the economical working of locomotive engines, their power should *be well proportioned* to the load they have to draw. It is remarked, apparently in allusion to one which we consider the best engine in our establishment, that to use an engine *capable* of drawing 200 tons, to drag loads averaging 50 tons, will be very like fastening eight horses to a post chaise. Although the remark savours of ridicule, I quite concur in it. It is a forcible description of the practical working of a line with gradients of 10 feet per mile, such a line as the imaginary one (A B) described in p. 49 of the report.

Now, on this line (A B), the engines going in one direction would have to exert a power of 126, and this at full speed, and in the other of 39, or as 200 to 62—a proportion not very different from the 200 to 50, which is mentioned only as something that would be very absurd.

Again, at another part of the report (p. 53), it is stated, that engines of little more than two-thirds the power of those on the Grand Junction Railway, and therefore of *considerably less weight*, would be sufficient on our line *from our flatter gradients*. Such an admitted reduction of 25 per cent. in locomotive power seems to me no mean economy to be obtained by these gradients, the effects of which are treated so lightly at other times; but these contradictory results are the necessary consequences of an attempt to argue against the simple facts, that the inclination of the line increases the resistance, and that if a regular speed is to be maintained, you must have power in proportion to that resistance.

All the foregoing calculations upon gradients have been limited to the two cases of 10 feet and 4 feet per mile. These are both unusually favourable, and their comparison therefore is not calculated to render the advantages so striking; but had the gradient of 4 feet per mile been compared with the more ordinary ones of 16 feet and 20 feet, the superiority would have told much more in the discussion of the general question of the value of good gradients. To supply this deficiency, I subjoin a table of the comparative effects of the same engine, with the same consumption of fuel, and travelling at the same speed on the level, and on the four gradients of 4, 10, 16, and 20 feet per mile, with a resistance of 8lbs. for friction, &c.; and for the sake of uniformity with the previous calculations, I take the same standard of 100 as the useful effect, or nett load, up the plane of ten feet:—

	Comparative Effective Power. Ascending.	Descending.
Level	170	170
4 feet per mile	134	226
10 feet per mile	100	400
16 feet per mile	77	1305
20 feet per mile	66;	the load once in motion would *run* of itself.

The discrepancy between these results and those given in the report does not arise merely from different data being assumed, and upon which there might be a difference of opinion; but from errors in the treatment of the calculation of the latter. I subjoin a similar table, calculated upon the basis of 10lb. per ton, being the total resistance on a level:—

Gradients.	Comparative Effective Power. Ascending.	Descending.
Level	156	156
4 feet per mile	129	195
10 feet per mile	100	297
16 feet per mile	80	556
20 feet per mile	69	726

By these tables the great superiority of a line approaching to the level is made apparent, not only is the effective power of the engine in that direction of the line which limits the load much greater, but the average work of the engine is performed more economically by the greater regularity of the resistance. On an inclination of ten feet per mile, as I have before shown, the engine, during half the time, is barely performing a quarter of the work of which it is capable. On gradients of 16 feet per mile, the engine during half the time is barely doing more than driving itself.

These are incontrovertible facts; whether the total resistance arises from friction, from the resistance of the atmosphere, or from whatever cause, the amount is about as stated, and the increase caused by the gradients is in the ratio stated in the above table.

It appears to me almost to weaken the strength and obscure the clearness of a demonstration which is mathematical in its correctness and certainty, to attempt to support it by reference to certain experiments in which other causes might have operated; but on the Great Western Railway we have every day, and with every train, such evident and striking proofs of the effect of gradients, that I should have thought it must be conclusive to any one who has had an opportunity of witnessing them.

With powerful engines and light trains, running at a good speed of 30 to 35 miles per hour, the changes of gradients, (which only vary from a level to 2 feet per mile, and to 4 feet per mile,) are perfectly perceptible in the increased or diminished speed, even without the assistance of a watch, and have been frequently detected by persons previously unacquainted with the levels.

It must always be borne in mind that the resistance arising from the gradients is a permanent evil which, once established by the completion of the works, cannot be remedied, and the probable future effects of this must therefore be seriously considered. In the course of a few years, as railway travelling becomes general throughout the country, and there are opportunities of reaching different parts of England by different roads, the usual results of competition will follow; prices will gradually be lowered; the number of travellers will become immensely increased; and the gross profits and expenditure become proportionably large; bearing then, particularly the latter, a much greater ratio to the original outlay than at present. The profits will then depend mainly upon the economy of transport, and then any saving in the current expenses will be felt in a far greater degree.

I shall now consider the subject of the width of gauge. The question of the disadvantage of differing in point of gauge from other railways, and the consequent exclusion from communication with them, is the first. This is undoubtedly an inconvenience; it amounts to a prohibition to almost any railway running northwards from London, as they must all more or less depend for their supply upon other lines or districts where railways already exist, and with which they must hope to be connected. In such cases there is no alternative.

The Great Western Railway, however, broke ground in an entirely new district, in which railways were unknown. At present it commands this district, and has already sent forth branches which embrace nearly all that can belong to it; and it will be the fault of the company if it does not effectually and permanently secure to itself the whole trade of this portion of England with that of South Wales and the south of Ireland; not by a forced monopoly, which could never long resist the wants of the public, but by such attention to these wants as shall render any competition unnecessary and hopeless. Such is the position of the Great Western Railway. It could have no connexion with any other of the main lines, and the principal branches likely to be made were well considered, and almost formed part of the original plan; nor can these be dependent upon any other existing lines for the traffic which they will bring to the main trunk.

At the London extremity, from the moment the junction, as originally proposed, with the London and Birmingham Railway was obliged to be given up, there existed no possibility of a connexion with any other line. London will always be the terminus of those main lines now established, and which approach it from distinct quarters, and the traffic of each will cease at this point; and, unless when two such lines unite to form a common entrance into the town, they will have no connexion with each other at this extremity.

The Great Western was therefore free to adopt its own dimensions; and none of the difficulties which would entirely prevent such a course in the north of England had any existence in the west; and consequently, all the general arguments advanced, and the comparisons made, on the supposition of such difficulties occurring—all excellent in case they did—are totally inapplicable to the particular case of the Great Western Railway, to which they have no reference whatever.

The reasons for adopting any increased width of gauge, and the particular dimension of 7 feet, have been so frequently before you, that it is unnecessary for me now to repeat them. The principal positive objection urged against it in the Report is the increased cost, while the mechanical advantages are doubted, but not disproved.

As regards the cost, I have repeatedly shown that this amounts at the utmost to a slight increase in the quantity of earthwork, and that the bridges, tunnels, &c., are not necessarily affected. Mr. Hawkshaw seems to be of the same opinion, as at p. 50 he classes the "tunnels of 30 feet diameter" among "the non-essentials," as "not absolutely consequent on the increase of gauge;" and at p. 50 he clearly limits the increased expense of construction to the earthwork, land, and permanent way. There is some inconsistency in these remarks, when compared with the estimate in page 52, where the width of tunnels is considered a consequence of the wide gauge, and a saving of estimated of 20 per cent. "in the tunnelling yet to be done, by the narrower gauge requiring 4 feet less width."

I have only here to repeat, what is really capable of the clearest proof—viz., that the greater width of tunnels, proposed by me for special reasons, which I have explained on more than one occasion, has nothing whatever to do with the wide gauge, inasmuch as tunnels of the ordinary width could be adopted, and the saving pointed out would not, therefore, be necessarily the result of the return to a narrower gauge. But the arguments advanced at p. 50 in the Report, to show the necessity of increasing the earthwork by 4 feet, are subsequently, without observation, applied to the tunnels. This error is occasioned by neglecting to give precise dimensions to quantities quite capable of it.

Arguments are founded upon the assumption that a certain width is necessary between the centre rails, for repairs. This is true; but the width should be stated in feet and inches. On the Liverpool and Manchester, this space is 4 feet 8 inches; and even with stone blocks, this is found ample for all the purposes of repair; indeed, it is the width which is so perfect in Mr. Hawkshaw's estimation. Four feet 8 inches, with stone blocks (which does not leave more than 2 feet 8 inches between the blocks,) are not equal to 4 feet with longitudinal wooden sleepers, which would leave from 2 feet 9 inches to 3 feet between them. Suppose 4 feet, however, to be necessary; then, with a 7 feet gauge, the distance from centre to centre of the two lines is 11 feet, which is the same as on the London and Birmingham, Grand Junction, and other lines, and which has been adopted to give a general increase of space. The width of tunnels, viaducts, &c., are *therefore not necessarily affected* by the 7-feet gauge. Neither do I understand how the cost of the permanent way can be sensibly increased. The weight of rail would be the same. The engines, in other respects similar, would be, at the utmost, only a few hundred weight heavier, consequent upon the increased length of axles and breadth of frames—the boilers, fire-box, wheels, cylinders, and working gear (about nine-tenths of the whole) remaining exactly the same; and even with our present heavy engines, the greatest weight upon one pair of wheels is not greater than upon the driving wheels of Mr. Bury's engines on the London and Birmingham railway.

If the strength of the rails be not increased, the mere distance between them cannot affect the expense of construction beyond the cost of a few cube feet of ballast per yard forward, and about eight loads of timber to the mile in transoms. If 150*l*. per mile is allowed for these sources of expense, it is far more than enough. This, with the 200*l*., assumed by Mr. Hawkshaw for the earthwork, and 50*l*. for one quarter of an acre of land, which he has not allowed for, makes 400*l*. per mile as the outside of the additional cost incurred in the first construction of the road on the 7 feet gauge. As to the consequent increased cost in the engines and increased expense of repairs, they are treated in so general a way that it is difficult, if not impossible, to meet what is said; but certainly actual experience satisfies me that eventually there will be no material difference in the first cost. The opinion of Messrs. Robt. Stephenson and Company, as quoted page 52, is, that it "will not be very considerable." The wear and tear, I am equally satisfied, will be diminished.

The whole subject of the diminished resistance arising from the increased diameter of wheels, and the opinion of the Irish commissioners in favour of it, is then disposed of in a summary manner. It is assumed that the bearings of the axles must be increased in the same ratio as the diameter of the wheels, and that hence no advantage would be gained, in so far as the friction was concerned; but such is not intended to be the case.

It is asserted that the grinding of the flanges against the rails must be more felt with a large wheel than a small one. No reason is given for expecting such a result, nor why this resistance should not be, as one might naturally expect, inversely as the square root of the diameter, and therefore diminishing with an increased diameter. As in the case of the gradients, however, the whole is set aside by one experiment; this experiment (pages 50 and 51) gives nearly the same result for wheels of 3 and 4 feet diameter. This is not surprising, as the difference in diameter was too small to be clearly detected by the very uncertain and unsatisfactory mode hitherto adopted for ascertaining the resistance. It appears to me also that they were not made under similar circumstances, or even on the same road, and the ratio of the bearings to the wheels seemed to be rather in favour of the small wheels. The experiment, therefore, appears to be perfectly useless and unavailable, and the writer says that he does not think it conclusive. Nevertheless, these are the only experiments adduced, whilst the point is assumed to be proved.

The next inquiry made is on the question of safety. I certainly never thought of the danger of upsetting from the narrowness of base, as a stage-coach occasionally does; and therefore I need not occupy your time in discussing the manner in which this imaginary argument has been advanced and then demolished. But I must call your attention to the extraordinary and contradictory general assertions (p. 51) that "if A be safe, there cannot be the smallest advantage in making B safer." This is a confusion of words. If safety, commonly speaking, meant a total absence of possibility of danger, then the statement is contradictory, and is not even sense; for if B is made safer than A, A cannot be perfectly safe. But safety is a term, after, all only used comparatively, and then the statement assumes this extraordinary shape—that if A be tolerably good, it is useless to seek anything better. Now, although no man, I believe, ever supposed that ordinary railway carriages were much exposed to the danger of being upset, yet no man could witness, as I have had the opportunity of doing, numerous accidents on railways of both dimensions, without being struck with the great difference in the susceptibility of the engines and carriages to being thrown off the rails on the 4 feet 8 inch gauge and on the 7 feet gauge. The reason is obvious enough: the oscillation and the velocity of the angular motion, or, in other words, the jerk caused by any departure from level in the rails, or from any open joint or obstacle, or from collision, must be much greater when acting on a 4 feet 8 inch base than on a 7-feet base, and I have seen many accidents on the 4 feet 8 inch rail arising wholly from this cause, while on the 7-feet gauge I have seen the same causes operating to a greater extent without producing any serious results. I believe, also, that at high velocities much of the resistance from the friction of the flanges, as well as the strain upon the carriages and liability to accident, arising from lateral motion, which is imparted to the carriage by angular motion, or rolling, and which must be lessened in the direct proportion as the base is extended. The great difference in the rolling motion of the engine chimney, when running at high speeds upon the 7-feet gauge, as compared with the same effect on the 4 feet 8 inches, was remarked at once by the engine-drivers sent by several of the manufacturers to erect their engines, and is familiar to all now engaged on the line, although the rails themselves were at that time undeniably in a bad state. Safety, therefore, may, and indeed must, be increased by the width of the gauge. As to the effects of the adoption of the wide gauge by the main trunks upon the branch lines likely emanate from it, as I said before, these branches have all formed part of the general plan, and were considered originally; and therefore the assumption of the writer, that there is uncertainty or danger upon this point, is not correct. The Bristol and Exeter Railway, which is the extension of the Great Western to the south-west of England, is well fitted to this gauge. A great extent of it will be the most level line in England, and is nearly straight. On the Cheltenham Railway, for four-fifths of the length it is free from any objectionable curve; and on the remainder there will be no curves of so small a radius, even in proportion to the 7-feet gauge, as there are on the Grand Junction and many other lines. The objections taken, therefore, are not applicable; and it seems to me that none of the grounds on which the writer founds his somewhat startling advice to alter all that has been done, are tenable. In fact they are none of them brought forward in a clear and tangible shape, except the debit and credit account in page 52.

I will begin with the last, or the credit account. The first item is the largest, and considering that it constitutes two-thirds of the whole, it is a very important one; yet there is no proof, there is not even one single reason given for supposing any such increase; the only reference to it that I can find is in the middle of p. 50, where these words occur:—"The permanent road will also cost more if of the larger dimensions than if of the smaller; for it avails nothing to compare a light rail on the larger gauge, with a heavier rail on the smaller gauge; such comparisons must be made when other things are the same, or they amount to nothing." The assertion here made is unsupported by a single argument or proof. What is meant by the truism contained in the allusion to the light rail and heavy rail I am unable to comprehend. I have quoted it lest it should have some reference to a wide and narrow gauge which I may not perceive.

I have shown, I think clearly, that 150*l*. per mile instead of 1000*l*. is the excess: this makes a reduction of 85,000*l*. in the assumed saving. The 400*l*. excess on the engine and tender I equally dispute; it is also unsupported by anything except the letter from Messrs. Stephenson, and their opinion is even much qualified: their concluding remark is—"If the power or dimensions of the engine be kept the same, the additional expense consequent upon an increase of guage will not be very considerable." In fact, the same engine, in all its material parts, and the same quantity of workmanship, answers for the one as the other; to widen the frame and lengthen the axles is all that is required; and even making no allowance for any increased facilities in the construction, 100*l*. will amply cover this,—say, 150*l*., as the increased expense consequent upon the wide gauge. This, of course, has no reference to any peculiar construction of the engine, such as greater evaporating surface, or larger driving wheels, which are not, in fact, consequences of the width of gauge, but which have been adopted with a view to economy of fuel and wear and tear.

In the next item I should add 50*l*. per mile for land, although neither upon earthwork, and still less upon land, have we 60 miles upon which we can effect the saving. The tunnelling, as I have shown by actual calculation of the measurement required, is not effected by the gauge. The account, therefore, stands thus:—

150*l*. per mile on 100 miles of permanent way . . .	£15,000
150*l*. less on 60 engines and tenders	9,000
250*l*. per mile on 60 miles of earthwork and land . .	15,000
Tunnelling—nothing.	
	£39,000

Instead of 156,000*l*., as given in the Report.

I now proceed to consider the debit account, in which I find an important omission. The change recommended from the 7-feet guage to the 4 feet 8½ inch, is supposed to occupy a year and a half; during this time no advantage could be taken of the extension of the line to Twyford, in the neighbourhood of Reading, which, if the opinions expressed in this Report are to be adopted, must be laid down with the narrow gauge, and it therefore would be useless until one of the lines of the same gauge was open. By this delay at least a year would be lost.

But besides this loss, another would be experienced by the confinement of the traffic to a single line. I believe it would be found impracticable to carry on our trade on a single line; there can be no doubt that it would be materially diminished, which, together with the loss of twelve months' traffic between London and Twyford, cannot fail to make a difference of upwards of 50,000*l*. The gross receipts upon the present line are about 80,000*l*. per annum; the extension of the line from 22½ to 32 miles, (thereby securing all the long traffic, which is now only partially obtained,) and the natural progressive increase of the traffic which would take place on the present line, cannot be estimated to produce less than 60,000*l*. more, or 140,000*l*. per annum. Supposing the expenses to be increased by 25,000*l*., there remains, as increased nett profits, 35,000.; to this add 15,000*l*., as a very moderate allowance for the reduction, to which I have alluded in our receipts, unavoidably consequent upon the working of only a single line, which would certainly not diminish our expenses.

The debit account, therefore, will now stand:—

Expenses of alteration and loss upon stock, as stated in Report (page 24)	£123,976
Loss of profits on the extension to Twyford . . .	35,000
Ditto on traffic to Maidenhead	15,000
	£173,976

Instead of £123,976.

And deducting the amount to be saved, 39,000*l*., it shows a sacrifice of 134,976*l*. as the result of the proposed alteration. Even if the assumed increase of 400*l*. on each engine were admitted, it would still leave 121,976*l*. as the balance against the change, instead of anything in favour of it. In addition to this clear loss, it should also be remembered, that after the conversion of the one line to Maidenhead from the broad to the narrow gauge, the other still remains to be altered. During the whole of this operation, let me repeat, the total traffic to Reading must travel on a single line, which, even admitting it to be possible, must necessarily cause a continued loss of traffic, with great additional inconvenience and expense, and serious risk of accident,—all so much in addition to the amount of sacrifice already calculated.

MAIDENHEAD BRIDGE.

On this head it is unnecessary to say more than that the defective part of the work has been condemned by me, and the contractor called upon to replace it, which he is now doing.

PERMANENT WAY.

The question of the construction of the permanent way appears to have been thought a very unimportant one: three lines of the Report are devoted to it, and these consist of the expression, in rather strong language, of an opinion unfavourable to the mode in which the attempt has been made; but whether the writer approves of the ultimate object sought to be attained—of the plan of continuous support—or not, does not in any way appear. This is to be regretted, as the writer has lately had some experience on this particular point, and it was supposed might have been able to give some useful information upon it.

LOCOMOTIVES.

The question of locomotive power is treated also very concisely; nothing whatever is stated, under this particular head, of the engines of the Great Western Railway. A few general principles are laid down, in almost all of which I perfectly concur,—viz., the necessity of proportioning the power of the engines to the loads; the advantage of keeping down the weight; the circumstance that the weight of the engine will depend on the average load to be taken, and the nature of the gradients. The comparison between the locomotive power supposed to be necessary on the Great Western and on the Grand Junction lines, is a powerful argument in favour of good gradients. On the whole, these principles are precisely those on which I have founded my arguments in the course of these observations, and I think they fully bear out the views I have taken; but the concluding observations of the Report appear to me to be the most strikingly erroneous views that I have yet had occasion to call your attention to, and still arising from the same mistake—that of omitting all consideration of increased profits to be derived from increased accommodation or improved conveyance—objects at which I have aimed.

In the last paragraph but one, after condemning, very properly, any great increase in the cost of a road for the sake of a system, it is asserted that "good gradients will be rendered of non-effect, as to economy, if the speed be greatly increased, for greater speed will entail greater cost, and be tantamount to steep gradients."

It seems to me, on the contrary, that the attainment of a greater speed at the same cost is economical, just as it is to make a better and more saleable article at the same price. And the next and last paragraph exposes still more strongly this fallacious principle, and may be taken as a fair sample of the theory of railway economy advanced in this Report. The words are—"And though the same results may perhaps be obtained on railways of better gradients, with more dead weights, than on railways of bad gradients, yet this seems to be merely bringing down the good line to the standard of the bad;—that is to say, if "more dead weights," or greater loads, are carried with "the same results," or at the same cost, no advantage is gained; so that, if natural or artificial means enable you to carry greater loads, and, in fact, *perform more work*, or, in other words, *carry on a greater trade with the same capital*, you are not to avail yourself of these advantages to extend your business, but merely to withdraw so much capital from a thriving concern. If the sole object were to reduce the out-goings to the lowest possible scale, without reference to the comparative receipts, such a maxim might be good. If the construction of the railway, and the maintenance and working of it, were a compulsory tax levied on the proprietors for the use of the public, without benefit to them, then, indeed, the only advantage of good gradients would be the diminution of exertion and of expenditure of power. To the beast of burden a good road is certainly of little consequence, if he is proportionably laden; but his owner would be surprised at being told that he could gain nothing by being able to carry more goods, because his horse would be worked as much, and worn out as soon, as when he carried less.

I shall now make a few observations on the remarks and the hypothetical cases which I before referred to, and I think, when I have called your attention to them, you will agree with me that they ought not to pass entirely unnoticed.

In p. 48 of the Report, the difference between the Great Western Railway and other railways is compared to the difference between a canal for barges and a canal for ships—a most exaggerated comparison, and one by no means diminished in effect by the qualification introduced by the words which follow, "though not to an equal degree." A ship-canal is a totally different thing from a barge-canal; it is most costly, and if considered as a mere channel for the conveyance of goods, is very ill adapted for the purpose. It is intended solely for the transport of the ships to some inland port. The only change introduced in the Great Western Railway is in the dimension of one of the parts, not for the purpose of carrying larger individual cargoes, but for the purpose of carrying the ordinary cargoes more advantageously. If a comparison be made with canals, it should be simply with the case of a canal which, being intended for quick service, or fly-boats, is made rather wider, to allow the boats more free passage through the water, and thereby diminish the resistance. The comparison apparently is thought to require some apology, as it is said not to be extraordinary "should it appear that the locomotives have twice the power of those on other lines;" and "should it be shown to be a parallel case to build a ship of 200 tons burthen, when there is no probability of ever obtaining a cargo of half the weight." This certainly is tantamount to the statement in a subsequent part of the Report, that the engines have this excess of power, and that we have, in fact, provided for a traffic four times as extensive as we can hope to obtain; yet, after producing this impression, the subject is dropped, and no attempt made in any part of the Report to prove it.

In the next paragraph (page 48) there is a remark that "it is one thing to design that which is pleasing in outline and grand in dimensions, and it is altogether another thing to design that which, under all the circumstances, shall best answer the end in view, one of those ends being a return for the capital invested."

I must deny altogether that such a distinction necessarily exists." To make that large for the sake of appearance which ought to be small, is unquestionably, very different from studying the right size and adopting it; but I think that when a work is evidently well adapted to the object for which it is intended, it is generally satisfactory to the eye; and that then there is rarely any difficulty in making it "pleasing in outline;" the distinction exists only with those who, like a bad architect, commence by designing the exterior of a building, and then make the interior arrangements subservient.

At the end of p. 48, a case is put which is strictly applicable, and which is solved in a manner to assist the subsequent arguments; but the solution seems to me to have no other merit, certainly not that of correctness.

It is supposed (what is indeed the actual case) that it is desired "to give the greatest impetus to the trade, and the greatest advantage to the town of Bristol;" and the way to do this is said to be, as if incontrovertible, "to connect it with the metropolis by a road on which parties could be carried for the smallest sum, and at a velocity not inferior to that at which they can be carried in any other direction." This is the first time I ever heard that to win the race it was sufficient to be not behind your competitor. If such were the rule in trade, why was the Liverpool and Manchester railway made? The means of communication were not merely not inferior to, but probably superior to any in England. Why were railways introduced at all, and the capital embarked in the general means of transit so enormously increased by the addition of totally new works? Stage coaches and canals left all towns exactly in the same position which is here said to ensure the greatest impetus to their trade. Besides, are there no points of inferiority in the case of the port of Bristol which have to be compensated for, in consequence of the superior local advantages of other ports? Bristol has, for some reason or other, fallen far behind Liverpool. Will it be of no advantage to the trade of this port, and thereby to the revenue of this railway, that it should have superior facilities of communication with London? Whether Liverpool continues at eleven-hours' or is reduced to eight-hours' distance from London, it may be said by some to be still a day's journey, while Bristol will be brought within four hours, or four and a half hours' distance; and if this is reduced to three hours, which is undoubtedly practicable, letters and orders may be transmitted and replied to during the business hours of the day; and precisely the same change introduced into the transactions of business that was effected by the Liverpool and Manchester railway, and a great increase in the trade of the place, and in the traffic of the railway must necessarily follow.

This doctrine of the all-sufficiency of a railway, without reference to its quality, and the inutility of attempting to influence the amount of traffic by increasing the advantages, appears, under different forms, in other parts, and I shall not again refer to it, but shall proceed to another part of the Report.

The adoption of a different gauge is compared, at p. 50, to the construction of a canal "in a country of canals, with locks of such a character as would totally shut out the boats of all the canals that surrounded it." Now, in the first place, as I have shown, the west of England is not a country of railways; and, in the next place, there is no similarity in the mode of conducting the carrying department of a railway and a canal. A barge, with its master and his family living on board, may go, and does occasionally go, without inconvenience, far out of the usual beat. Railway carriages and waggons must belong to the particular line on which they run; and, except in such cases as the Grand Junction and Birmingham railways which form in fact one line, although they happen to be made by two companies, it will never pay to trust them in the hands of others.

On the subject of the wide gauge, the opinions of Mr. Booth, of the Liverpool and Manchester railway, (which had been previously expressed in a letter to the Irish Commissioners,) and of Mr. G. Smith, of the Leeds and Selby railway, are quoted in favour of the 4 feet 8 inch guage, and their answer in the negative, given apparently to the direct question whether they thought there was any want of safety, or danger of overturning, on their own railways. The case is purely hypothetical. I never heard of the danger of overturning being advanced as an objection to the narrow gauge, although I have seen such a thing happen; and whether the objection be real or imaginary is the question to be decided by such a reference? At any rate the directors of the Great Western Railway were quite competent to select the referees for its decision.

I have the pleasure of being personally acquainted with both these gentlemen, and entertain the greatest respect for them, but I should never have thought of asking them such a question. If before building the Great Western steam-ship we had written to some of the highly respected and talented gentlemen who command the New York liners, and asked them if they considered there was any danger or inconvenience in the use of sails, and whether they should prefer steam, I think we might have anticipated their answers.

I shall here close my observations with the expression of my regret, that the manner in which the important questions at issue have been treated in the Report has of itself prevented the discussion leading to any very satisfactory or useful conclusion. It has been almost impossible to do more than to show that, whatever may be the state of the case, the views taken in the Report, and the arguments advanced, are incorrect, and prove nothing. Another opportunity will probably occur of entering more fully into the real merits of the question, and for that I shall be prepared.

I am, gentlemen, your obedient servant,

(Signed) I. K. BRUNEL.

London, Dec. 13th, 1838.

REPORT OF NICHOLAS WOOD, ESQ.

TO THE DIRECTORS OF THE GREAT WESTERN RAILWAY.

Killingworth, Dec. 10th, 1838.

* * * * Your instructions were, that I should undertake an examination of that portion of the Great Western Railway now completed, and investigate the result of the whole system which has been adopted; and my attention is particularly directed to those points which may be said to constitute the peculiar features of the Great Western line, as contrasted with those of other railways, including in such inquiries the construction and efficiency of the engines, as well as every matter connected with the locomotive department of the company.

The Great Western Railway differs from the ordinary railways, in the width of gauge adopted, in the construction of the rails employed in framing the road, and in the adoption of much larger driving wheels than ordinary in the locomotive engines.

The subjects for consideration are therefore comprised under the following heads of inquiry, viz., the width of gauge, the mode of constructing the road, and the efficiency, power, &c., of the locomotive engines.

The increased width of gauge might have been adopted, and engines of the same description as those used on other railways might have been used, and it does not necessarily imply that the adopting an increased width, should render necessary the particular mode of construction adopted by Mr. Brunel, except in one point of view in which Mr. Brunel has put it, viz.:—" That the increased width of gauge was necessary for the accomplishment of a high rate of speed, and that he believes continuous timber bearings to be a most essential improvement where high speeds are to be obtained." Still, as the two questions are in some degree distinct, we shall in the first instance consider them separately, and shall afterwards consider them in their connexion with each other, as advanced by Mr. Brunel; and as the elucidation of these two heads of inquiry, includes that of the power of the locomotive engines, we shall not in this place make their consideration a distinct question.

In order, therefore, to bring the subject clearly before you, I shall first of all point out the *objects*, so far as I can learn from the published documents of your body, and from the reports of Mr. Brunel, which have been expected to be realized by these departures from the more general plan of constructing and working railways; I shall then state some of the most prominent objections which have been made against the system, after which I shall give, in detail, the inquiries and experiments which appeared to me necessary, to ascertain how far these benefits have been, or appear likely to be realized, and to what weight the objections appear to be entitled. The result of these inquiries and experiments will be next considered, and with these materials, in obedience to your instructions, the system of construction of the Great Western Railway will be contrasted with the most improved railways of the ordinary construction and width of gauge.

Width of Gauge.—The width between the rails of all the public railways in England is four feet eight and a half inches, the width of the Great Western Railway is seven feet; the difference is therefore nearly one half more, or two feet three and a half inches. From the documents previously alluded to, from a careful perusal of Mr. Brunel's reports, and from personal communications with that gentleman, the following appear to have been the prominent advantages expected to be derived from the increased width of gauge, and which induced the adoption of the width of seven feet.

Attainment of a high rate of speed.—On this point Mr. Brunel remarks, " with the capability of carrying the line upwards of fifty miles out of London, on almost a dead level, and without any objectionable curves, and having beyond this, and for the whole distance to Bristol, excellent gradients, it was thought that unusually high speed might easily be attained; and that the very large extent of passenger traffic, which such a line would certainly command, would ensure a return for any advantages which could be offered to the public, either in increased speed or in increased accommodation." For Mr. Brunel remarks, " I shall not attempt to argue with those who consider any increase of speed unnecessary, the public will always prefer that conveyance which is the most perfect, and speed within reasonable limits is a material ingredient in perfection in travelling," and the attainment of high speed appeared to involve he question of the width of gauge.

Mr. Brunel also considers, " that it would not have been embracing all the benefits derivable from the favourite gradients of the Great Western Railway, unless a more extended gauge was to be adopted, for if carriages and engines of a certain weight have not been found inconvenient upon one railway, greater weights may be employed, and the same results obtained on a railway with better gradients; and to adopt a gauge of the same number of inches on the Great Western Railway, as on the Grand Junction Railway would, in fact, amount practically to the use of a different gauge on a similar railway, for the gauge which is well adapted to the one is not well adapted to the other."

Mechanical advantage of increasing the Diameter of the Wheels, without raising the Bodies of the Carriages.—This comprehends what is deemed by Mr. Brunel, the most important part of the advantage of an enlarged width of gauge, viz., the reduction of friction by the increased diameter of the wheels, while at the same time by being enabled to pl[illegible] body of the carriage within the wheels, the centre of gravity of the carriage is kept low, and greater stability and steadiness of motion is expected to be attained. Four feet wheels have been put upon the carriages at present in use upon the line, but Mr. Brunel states " that he looks forward to the employment of wheels of a larger diameter; and that he has been influenced to a considerable extent, in recommending the increased width of gauge, by its capabilities of prospective improvements, which may take place in the system of railroads. He states, " that though there are some causes which in practice slightly influence the result, yet practically the resistance from friction will be diminished exactly in the same ratio that the diameter of the wheels is increased," and " considering that the gradient of four feet per mile only presents a resistance of less than two pounds per ton, and that the friction of the carriages on ordinary railways amount to eight or nine pounds per ton, being 8-10ths of the entire resistance, any diminution of the friction operates with considerably more effect upon a road with favourable, than one with more unfavourable gradients;" and he further says, " I am not by any means at present prepared to recommend any particular size of wheels, or even any increase of the present dimensions. I believe they will be materially increased; but my great object would be in every possible way to render each part capable of improvement, and to remove what appears an obstacle to any great progress in such a very important point as the diameter of the wheels, upon which the resistance which governs the cost of transport, and the speed that may be obtained so materially depends."

Admits all sorts of Carriages, Stage-Coaches, &c. to be carried within the wheels.—Presuming that the adoption of wheels of a larger diameter is found beneficial, to the extent expected by Mr. Brunel, it became necessary that the carriages to be conveyed should be placed upon platforms within the wheels, to keep them as low as possible, which could not be done with carriages on railways of the ordinary width, a wider gauge seemed therefore necessary for this purpose.

Increased facilities for the adoption of larger and more powerful Locomotive Engines, for the attainment of higher rate of speed.—Much stress has not been laid upon this by Mr. Brunel, although it has been alleged that great difficulties exist and that considerable expense is incurred by being obliged to compress the machinery into so small a space; and consequently, that a greater width of gauge would enable the manufacturer to make a more perfect machine, and by having more space for the machinery, the expense of repairs would be lessened.

Increased stability to the Carriages, and consequently increased steadiness of motion, not from any danger to be apprehended, by the centre of gravity being higher in carriages of a less width; but that higher carriages are more liable to oscillate upon the railway, than carriages of a greater width and less height, and that a considerable part of the friction is occasioned by the oscillation of the carriages throwing the flanches of the wheels against the rails.

These appear to be the more prominent advantages set forth by Mr. Brunel, as consequent upon the adoption of an increased width of gauge. I have taken the extracts from the report to the Bristol meeting, in preference to quoting from Mr. Brunel's communications to the directors, inasmuch as that report is before the shareholders; and also in that report Mr. Brunel enters somewhat minutely into details on the subject, and gives in a more determined and explicit plan the substance of all his communications to the directors on the subject. It would have increased the bulk of this report unnecessarily to have given all Mr. Brunel's reasons for the adoption of the increased width set forth in that document, and this is also unnecessary, as the report itself is before the shareholders and can be referred to. These representations and recommendations of the engineer, appear to have been the principal reasons which induced the adoption of an increased width of railway, as stated in your report to the shareholders, at the half-yearly meeting of the 25th of August, 1836.

The objections which have been advanced against the adoption of this departure from the ordinary width of railways, have been principally the following, viz.

The increased cost of forming the road track of the Railway, in consequence of a greater width of base required for the superstructure of the rails, and upper works. That the carriages were required to be larger and heavier. That the increased width of gauge caused additional friction in passing through the curves. That it entailed a greater expense of constructing the engines and carriage, increased liability to the breakage of axles, &c. That it prevented a junction of the Great Western with other railways; and above all, that there were no advantages gained, commensurate with the increased expenses and inconvenience of such a departure and disconnection from railways of the ordinary width, and several other objections which have been urged by different persons against the system, which it is not necessary to enumerate.

Previously to entering upon the consideration of the presumed benefits and objections incidental to the width of gauge, it will be advisable to bring before you the second part of the system of Mr. Brunel, viz.: the mode of constructing the railway, and in doing so I shall pursue the same plan as in the case of the consideration of width of gauge; first of all to point the reasons which seem to have influenced Mr. Brunel in the recommendation of this particular plan, and the improvements over other plans which he anticipated from its adoption; I shall then briefly state some of the principal objections which have been urged against it; and lastly, detail and report to you the mode I have deemed adviseable to investigate, and determine all these conflicting questions, and then give the conclusions, which appear to me to result from the enquiries and experiments I have made.

Construction of the Road.—It will not be necessary for me to enter into a detailed description of Mr. Brunel's plan of constructing the Great Western Railway, furtherthan what is absolutely necessary to explain the principles of construction, and in what respects it differs from that of other railroads.

The plan adopted by Mr. Brunel is that of a continuous bearing of timber with piles upon which the iron rails that constitute the track of the wheels are placed.

The construction may be thus shortly described: Longitudinal timbers of a scantling of from five to seven inches in depth, and twelve to fourteen inches in breadth, and about thirty feet long are placed along the whole line. Then these timbers are bolted to cross sleepers or transoms at intervals of every fifteen feet; double transoms each six inches broad and nine inches deep being placed at the joinings of each of the longitudinal timbers, and single transoms of the same scantling being placed midway between the joinings. These transoms stretch across, and are bolted to all the four lines of rails. Within the two lines of rails of each track, piles of beech are driven from the upper surface of the railway into the solid ground, so as to retain a firm hold thereof, and the transoms are bolted to the heads of these piles.—*Vide Description and Construction of the Railway, in Journal No. 7, page 166, Vol. I.*

This plan is pointed out very clearly by Mr. Brunel, in his report to you on the 22d of January, 1838, and presented to the shareholders at the half yearly meeting on the 27th of February, 1838.—*Vide Journal No. 7, page 166, Vol. I.*

At the subsequent meeting (Oct. 10th, 1838) of the Great Western Railway proprietors, Mr. Brunel thus gives his reason for the adoption of this plan of constructing the road:—

"The mode of laying the rails is the next point which I shall consider. It may appear strange that I should again in this case disclaim having attempted anything perfectly new, yet regard to truth compels me to do so. I have recommended in the case of the Great Western the principle of a continuous bearing of timber under the rail, instead of isolated supports, an old system recently revived, and as such I described it in my report of January, 1838; the result of many hundred miles laid in this manner in America, and of some detached portions of railways in England, were quite sufficient to prove that the system was attended with many advantages, but since we first adopted it these proofs have been multiplied; there need now be no apprehension. There are railways in full work upon which the experiment has been tried sufficiently to prove beyond doubt, to those willing to be convinced, that a permanent way in continuous bearings of wood may be constructed, in which the motion will be much smoother, the noise less, and consequently—for they are effects produced by the same cause—the wear and tear of the machinery much less; such a plan is certainly best adapted for high speeds, and this is the system recommended by me and adopted on our road. There are, no doubt, different modes of construction, and that which I have adopted as an improvement upon others, may, on the contrary, be attended with disadvantages. For the system I will strenuously contend, but I should be sorry to enter with any such determined feeling into a discussion of the merits of the particular mode of construction. I would refer to my last report (*vide Journal No. 12, page 325, vol. 1*) for the reasons which influenced me, and the objects I had in view in introducing the piling; that part which had been made under my own eye answered fully all my expectations."

These appear to have been the reasons for the introduction of this system of railway construction, and the objections raised against it have been—The increased cost of construction beyond that of other modes,—the additional expense of keeping it in repair;—and that it does not accomplish the objects proposed by Mr. Brunel, in recommending it to your notice,—that the motion of the carriages is much greater than upon ordinary railways of the best construction,—and that there is a considerable increase of resistance to the carriages.

The professed advantages to be derived from the increased width of gauge, and the construction of the road by continuous bearings and piles, are so extensive and numerous, while on the other hand, the objections alleged against them are equally so, that it appeared to me, as stated previously, with the exception of awaiting the result of the test of time, there was only one mode of determining these complicated questions with any degree of satisfaction, viz., to endeavour to investigate as many of the points as possible, by experiments instituted for the express purpose, and to ascertain if by this mode such a number of facts could be obtained as would, with the aid of the experience already obtained of the working of the system, enable me to arrive at conclusions which would, to unprejudiced persons, determine the important questions submitted to me.

On a review of all the proposed advantages and above-enumerated objections, the most important points to be determined by experiment appeared to me to be comprehended within the following heads of inquiry:—

1. The question of the attainment of a higher rate of speed than on other railways; whether the increased width of gauge is, or is not, either necessary or best adapted for the accomplishment of this object, and to what extent.
2. The mechanical advantage or diminution of friction, by being enabled to increase the diameter of the wheels, without raising the bodies of the carriages; and in what respect, and to what extent, the friction or resistance of the carriages is affected by, or bears upon the peculiar construction of the road.
3. The comparative advantage or firmness of base, or road track, of the Great Western Railway, with continuous timber bearings, either with or without piles, and if it does or does not produce a greater steadiness and smoothness of motion to the carriages, and to what extent.

These were the questions which appeared to me could not be determined in any other way than by experiment, but which appeared to be capable of solution by that method, and which likewise appeared to constitute the foundation of the entire system; for if the plan was not either necessary for the realization, or did not effect a greater rate of speed than ordinary railways; if no diminution of friction was accomplished, and if no increased steadiness of motion to the carriages was produced, at least, a very considerable portion of the inducements for a departure from the ordinary plan would be destroyed: but if, on the contrary, the whole or some part of these desiderata were accomplished, then it remained to be determined whether the advantages did or did not counterbalance the disadvantages or objections to the system.

Attainment of Speed.—The first question to determine was, therefore, that of the attainment of speed. The most conclusive manner of effecting this appeared to be, to subject all the different descriptions of engines upon the line to experiment; to ascertain at what rate of speed they could travel, the loads they were capable of dragging at different rates of speed, and the comparative power required to accomplish these different performances. Having thus obtained the power of the Great Western Railway engines upon that railway, by instituting a similar set of experiments on other railways; we then had the comparative result of the engines as to speed, and performance upon the railways of the ordinary width and plan of construction, and upon the Great Western Railway.

A set of experiments for the purpose of ascertaining the performances of the several engines on the Great Western Railway was therefore commenced, and were conducted as follows:—

A certain number of first and second class carriages were selected and weighed; they were then loaded with such a weight as would equal that of their full complement of passengers, with their luggage. A certain number of trucks were also selected, weighed, and loaded with the weight which they were calculated to carry.

The engine selected for the experiment was weighed, and also the tender,—the quantity of coke in the fire-grate of the engine was carefully observed at the commencement of the experiment, and also the quantity of water in the tender. The engine was then attached to the carriages fixed upon for the experiment, put in motion, and proceeded to the end of the stage without stopping. The coke having been previously weighed into bags, the quantity put into the fire-grate during the journey was recorded, and at the end of the trip the fire-grate was filled up, as nearly as could be estimated, to the same height above the fire-grate as it was at the commencement of the trip, and the quantity thus consumed correctly ascertained. The quantity of water at the beginning of the trip being known, the boiler was kept to the same height during the journey, the quantity of water left in the tender at the end of the journey was gauged, and thus the quantity evaporated in the trip was obtained.

The mode of conducting the experiments was this:—Commencing at Paddington, the engine dragged the train from the depot to the first half-mile post, when it was stopped; the steam was then applied to the cylinders, and the time noted; for the first mile the time was recorded at every 110 yards, for the purpose of ascertaining the progress of obtaining the average speed, and afterwards at every quarter mile. The train then proceeded until it arrived at the twenty-first mile post, when the steam was shut off from the cylinders, and the train allowed to come to rest of itself. The quantity of coke consumed, and water evaporated, during each journey was ascertained as previously explained; and the rate of speed being taken at every quarter mile, the rate of velocity was also obtained, not only during that part of the journey at which a maximum rate of speed was kept up, but also the time occupied in getting up the speed, and also of bringing the train to a state of rest. The same process was observed in the return trip from Maidenhead to Paddington; the engine and train was brought up to the twenty-second mile post and stopped, the steam thrown upon the pistons, and the time, coke, and water, ascertained in the same manner as in the former case.

Table I. is the result of the experiments of the power of the Locomotive Engines on the Great Western Railway, arranged in a tabular form, &c.;

By classifying these experiments, under the respective loads by which the powers of the engines were tested; we have the comparative results, as regards the performances of the different engines with performances of the different engines with specific loads, and the consumption of fuel, or power required to drag these loads at certain rates of speed.

On attentively considering the result of these experiments, as exhibited in the following tables, we find that the extreme mean maximum rate of speed accomplished by these engines, has been 41.15 miles an hour, with the North Star Engine, but the load which was taken at that rate of speed was only 15 tons. It may here be observed, that the rate of speed shown in these tables, is the mean rate from the time the engine obtained its full speed, until the steam was shut off at the end of the experiment; and comprehended a distance generally of 19 miles, as may be seen on inspecting the tables in note E, Appendix. A greater extreme rate was accomplished for a short distance, during some of the experiments, as much as 45 miles an hour. The above expression of the maximum mean rate of speed, is therefore the average rate of travelling from one end of the stage to the other, after the engine had got into full speed, and until the speed was again checked at the end of the stage.

A rate of 40½ miles an hour has, it will be seen, been accomplished by another engine, the Apollo, but with a load of only nine tons; when the load was increased, both with this engine and with the North Star, the speed was correspondly reduced. The result of these experiments show that to effect a mean rate of about 40 miles an hour, exclusive of the time of getting up the speed and stopping at the termination, between the two ends of a stage, about twenty miles in length, the load cannot be more than from 15 to 20 tons, with engines of the power of the North Star.

TABLE I.

RESULT OF THE PERFORMANCES OF THE DIFFERENT ENGINES ON THE GREAT WESTERN RAILWAY.

It may be here remarked, that unless very large and heavy tenders are conveyed with the engines, the stages cannot be of a much longer distance than twenty miles; the quantity of water evaporated in this distance, by the North Star Engine, being upwards of three tons.

The performance with the North Star was with a six wheel, and a four wheel passenger carriage, capable of containing 56 passengers; the experiment with the Apollo Engine was with a six wheel carriage capable of containing 32 passengers, the full complement of luggage in both cases being allowed.

It is scarcely necessary to state that, this is a load which cannot be considered a profitable or adviseable one, to be fixed upon as a standard for the weight of the trains; or such a load as should be considered to be the weight of the first class trains on the railroad for permanent adoption. It is only necessary to refer to the experiments to see, at what a sacrifice of power and consumption of coke this rate has been accomplished, to arrive at once at the conclusion, that if such a rate of speed cannot be kept up except at such a sacrifice, the rate must be reduced.

The Æolus engine with 24 tons, realised a rate of 37 miles an hour, and the twelve inch cylinder engines with 18 tons, accomplished a similar p rformance: these are likewise loads below that which it will be necessary to provide for the regular traffic of the railway.

We come now to the next load, on which experiments were made, viz. 32 tons; this would provide accommodation for about 112 people with their luggage, with 2 six, and 2 four wheel first class carriages; and with this load the North Star accomplished a rate of nearly 37 miles an hour, and the other engines about 34 miles, This is likewise a less load than can be reckoned upon for the permanent working of the line, as it does not allow for the conveyance of private carriages, which must always be calculated to accompany the swift or first class trains.

With a load of 50 tons, the speed realised by the Northern Star is nearly 35 miles an hour;—with the Œolus 32 miles;—but with the other engines only 26½ miles an hour.

When the load is increased to 80 tons, the North Star engine performs a rate of nearly 33 miles an hour; but the performance of the Œolus engine is diminished to 24½ miles an hour; and we see that a rate of 22½ miles an hour is the performance of engines such as the Venus, Neptune, and Apollo, with 12 inch cylinders, and 6 and 7 feet driving wheels, respectively.

It does not appear, therefore, that with the best of the engines at present upon the Great Western Railway, a greater velocity can be calculated upon; at the mean maximum rate of speed than 35 miles an hour, with such loads as may be expected to constitute a first class train. For extraordinary purposes, with a diminished load, a rate of 40 miles may be attained, but looking at all the circumstances incidental to railways, with engines and trains travelling at the maximum rate of speed, it does not appear to me, that any standard equal to 40 miles an hour can be depended upon in practice. The weight of two first class carriages, one with six wheels, and one with four wheels, and of two second class close carriages, one with six wheels, and one with four wheels, with their complement of passengers and luggage, will weigh about 31 tons; but this does not allow of any trucks for the conveyance of gentlemen's carriages, or for horse boxes. Upon the London and Birmingham Railway, since it has been opened throughout, the average weight of the trains, including passengers, passengers' carriages, carriage trucks, horse boxes and luggage vans, has been about 65 tons; this includes both first-class and mixed trains, the former being upwards of 50 tons and the latter about 70 tons. Taking this as a standard for the Great Western Railway, it does not appear that, for the first-class trains a less weight than 50 tons can be calculated upon; and with this weight the experiments show that a mean rate of 35 miles an hour between the stages, after getting up the speed, and before its being checked may be accomplished, under circumstances similar to those experienced during the time these experiments were in being performed, and with engines of the power of the North Star. And it will be seen that with a load of 80 tons, which would not much exceed the weight of a second class train, a velocity of nearly 33 miles an hour can be maintained, during the time the engine is at the full rate of speed.

Taking 35 miles an hour, therefore, as the mean maximum rate of speed between the stages, it will have to be considered what general average rate can be kept up between one end of the line and the other; in this calculation we have to take into account, the time lost in getting up the speed, and in stopping the train, the time lost at each station, and all the vicissitudes of wind, weather, and incidental casualties. On the other hand I think it my duty to explain, that these experiments, which are here brought forward as a standard for the assumption of this rate of speed on the Great Western Railway, though it is not expected that more weight should be placed upon them than upon experiments generally, which must be considered as exhibiting more favourable circumstances than the everyday practical result; yet it must be taken into account, that the road for three or four miles from one end of the line was under repair, and would not therefore present what may be considered an average result, or what may be expected to be the permanent result when the road is in the best possible order. We shall see afterwards to what extent this may be supposed to influence the general result; I thought it my duty, however, to mention it in this place, that every circumstance connected with the enquiry likely to operate, in any degree whatever upon the general result, should be brought into consideration.

On a mere inspection of these tables, every person must be struck with the enormous increase of power required to effect a high rate of speed, or a rate of 40 miles an hour, compared with that which is required to propel a load at the rate of about 20 miles an hour. We see the North Star engine, dragging 166 tons at the mean rate of 23.3 miles an hour; while the same engine under similar circumstances is only capable of dragging 15 tons at the rate of 41.15 miles an hour. Again the Æolus engine, drags 104 tons at the rate of nearly 23 miles an hour; and only 24 tons at the rate of 37.28 miles an hour. The engines of less power exhibit precisely the same results, we see them dragging 50 tons at 26½ miles an hour, and only nine tons at 40½ miles an hour.

If this had been the result of theoretical deduction, some suspicion might have existed of its accuracy, but the above is the result of carefully-conducted experiments, made under precisely similar circumstances; and although it might have been desirable that a greater number of experiments had been made in corroboration, there can be no doubt that the results as shown by this experiment exhibit, if not strictly so, sufficiently correct data for all we require in a practical point of view.

I am aware that this aggregate result is composed of the effect of the engines, the effect of the road, and the resistance of the carriages; and that each of these effects are liable to modification, to the extent to which each of them influence the general result, and to which they are susceptible of further improvement. We shall afterwards see to what extent each of these operate in producing the general result, and we shall also see that this result is completely and satisfactorily made out by subsequent experiments, on each of these sections separately; still, in practice, it is the aggregate result to which we must look, and by which we must be guided in our inquiries into the entire system. It is of the utmost importance to inquire into the causes, that we may know how far the general result is capable of improvement, and to what extent; but in practice, conclusions drawn from experiments on a working scale and character, must carry with them considerable weight as a standard.

I must here revert to the often repeated expressions of opinion, that in laying down any standard of power in engines, and especially any standard with reference to the power of locomotive engines, it should be a varying one, dependant upon their presumed increased powers; and, that looking back to the rapid strides of improvement made in the engines, we may naturally look forward to further improvements, and that, therefore, our calculations should rather be founded upon what may probably be the powers of these engines in future, than upon the powers they exhibit at the present time. The force of this is irresistible, but we must not, where the result involves the expenditure of an immense amount of capital, yield to prospective theoretical improvements, unless they carry with them strong, and almost certain grounds of practical realisation. The great impulse of improvement given to these engines has has been their powers of evaporation, in producing a sufficiently rapid evolution of steam with an engine of a tangible weight. The system of small tubes has effected more than could at one time be reasonably expected, and we now not only accomplished an immense rapidity of production of steam; but we have likewise effected this without any waste of fuel, and this is a most important element in the consideration. By an inspection of the tables it will be seen, that the average weight of coke required to convert a cubic foot of water into steam, is not greater than what is required by the best constructed stationary engines, and less than Mr. Watts' standard, viz. 8lbs. of coal to each cubic foot of water. When we consider the ingenuity exercised for so long a period upon this part of the economy of stationary engines, with so little effect, and this, with engines infinitely more favourably circumstanced than the locomotive engine, it becomes extremely questionable to what extent we ought to carry speculations founded upon a presumed increase of evaporating power of these engines. But allowing to the most sanguine every possible extent of imaginative improvement, and supposing that we could effect an equally economical and as great a rapidity of production of steam, with the North Star, as with engines of the weight of the Venus, Neptune, and Apollo, which are only of half the power, and which, it may be presumed, would be the limits of speculation by the most fertile mind, what do we gain, we have a saving of two tons weight. Or, if we were to go even further, and take the lightest engine working on the ordinary railroads, and suppose their powers of evaporation to be doubled, we gain no more than five or six tons upon a railway of the width of the Great Western, and this would give us 20 tons at 41 miles an hour, instead of 15 tons, and so in proportion at other velocities. The only reasonable speculation of future improvements, is in the expectation that increased evaporating powers may be given to such engines as the North Star; and that retaining the same weight of the present most powerful engines, we may so increase their evaporating powers as to produce an increase of effect. Here, however, we have practical data to guide us even in this respect in these tables: the comparative evaporating powers of the Æolus and the North Star, are 165 : 115, and the Venus 165 : 106. These tables show, that with such an increase of powers of evaporation, no more than about three miles an hour is gained by the North Star over the Æolus, both engines being of the same weight. It results, therefore, from these experiments, that it would, practically considered, be imprudent to indulge in speculations which are only necessary in case of considerable improvements being effected in the locomotive engine, and by which a much higher rate of speed can be realized than these engines are at present capable of effecting:— we shall afterwards see that there is a limit to the velocity of railway trains, by an element over which we have no control, and that it would be impolitic in a practical or commercial point of view, to attempt more than a certain rate of speed.

Having thus obtained, as far as the time permitted, the power and capabilities of the engines upon the Great Western Road, the next step was by a similar set of experiments to obtain the powers of the engines on railways of the ordinary width and construction. To accomplish this, application was made to the directors of the London and Birmingham Railway, who very handsomely granted permission to make any experiments which might not interfere with the traffic upon the road. When, however, it is considered that these experiments can only be made in the interval between the trains passing along the line; that on the Great Western Railway, where, from the line being short, much greater facilities are afforded for making the experiments than upon a long line of road, the experiments occupied from the 13th of September to the 13th of October; and when it is also considered that these experiments involve considerable expense, and the almost exclusive attention of the persons connected with the locomotive department, it is quite unnecessary to state that it was extremely difficult to avail ourselves of the permission granted by that company, without such interference with the regular traffic of the road as would have been unjustifiable.

The engines upon these railways, however, are not so varied in their construction as those of the Great Western Railway, and therefore a less number of experiments were necessary; for, instead of having to determine the power of each different kind of engine, it only required experiments to determine the power of almost one engine, the other being so nearly alike, the performance of one correctly ascertained was, in fact, the standard of power of the whole.

Mr. Robert Stephenson, in the most handsome manner, placed at my disposal some experiments made on that railway on the powers of their engines during the summer of this year, and, for the purpose of checking these by my own personal observation, he arranged and accompanied me on an experimental trip from the Camden Town station to Boxmoor and back, and gave me an opportunity of making other trips to corroborate the accuracy of his experiments.

Table III. will show the result of those experiments on the London and Birmingham Railway.

TABLE III.

ACCOUNT OF THE PERFORMANCES OF THE ENGINES ON THE LONDON AND BIRMINGHAM RAILWAY.

NAMES OF THE ENGINES.	Load. Carriages.	Load. Engine and Tender.	Load. Gross Load.	Rate at full Speed.	Mean Rate.	Pressure of Steam per Square Inch.	Coke consumed. During Trip.	Coke consumed. Per Ton.	Coke consumed. Per Mile.	Water evaporated. During Trip.	Water evaporated. Cubic Feet per Hour.	Water evaporated. Pounds of Coke per Cubic Feet.
	Tons.	Tons.	Tons.	Miles per Hour.	Miles per Hour.	lbs.	lbs.	Of Goods. lbs.	Gross Load. lbs.	Galls.		
Harvey Combe.	32·65	17·5	50·16	32·88	30·51	50	434	·89	·47	300	83·81	8·84
	53·45	17·5	70·95	32·4	28·53	50	601	·59	·4	506	105·9	7·59
	64·36	17·26	81·61	25·53	21·85	50	391	5·40	·36	317	70·66	7·62
Bury's Engine.	34·45	16·32	50·77	32·41	31·29	50	606	1·01	·55	420	91·	8·9
	53·91	16·85	60·76	32·04	29·82	50	590	·58	·41	405	94·42	8·12
	67·2	16·33	83·53	23·81	19·42	50	1220	·36	·29	935	56·81	8·11

These experiments, the results of which are shown in the above table, were made, as will be seen by an inspection of the section, upon a part of the railway, the gradients of which are very variable; the inclination being in some parts 16 feet in a mile, and are the mean result in both directions.

Table IV. is a summary of these experiments arranged for comparison with those on the Great Western Railway.

TABLE IV.

TABLE OF THE POWERS OF THE ENGINES OF THE LONDON AND BIRMINGHAM RAILWAY.

Load in Tons of Carriages and Passengers.	Harvey Combe engine, 12 inch cylinder, 5 feet wheels. Maximum speed in miles per hour.	Harvey Combe engine, 12 inch cylinder, 5 feet wheels. Coke per ton per mile in lbs.	No. 15. Mr. Bury's engine, 12 inch cylinder, 5 feet wheels. Maximum speed in miles per hour.	No. 15. Mr. Bury's engine, 12 inch cylinder, 5 feet wheels. Coke per ton per mile in lbs.
32.65	32.88	.89	—	—
34.45	—	—	32.41	1.01
53.45	32.4	.59	—	—
53.91	—	—	32.04	.58
64.36	25.53	.504	—	—
67.20	—	—	23.81	.36

From this it will be seen that, on a railway of the ordinary width, where the gradients are variable, and where the resistance is more than doubled in some parts, a mean velocity of 32 miles an hour may be maintained with loads varying from 32 to 54 tons. These experiments were made for the express purpose of comparison with those on the Great Western Railway, and with the same loads; and they are, therefore, presented as experiments for such a comparison. I have done this in preference to producing as comparisons other experiments made on the Grand Junction, and Liverpool and Manchester Railways; as if I had done so, these experiments not being made in the same manner, many explanations would have been required; it will, however, be seen, on inspecting the results of the other experiments, that the general comparative result of the performances of the engines on the London and Birmingham Railways is corroborated by those other experiments.

On comparing the results of these experiments with those made on the Great Western Railway we find, that with the same load, or with a load of 32 tons, a greater rate of speed is accomplished by the North Star engine; but that the performances of the engines on the London and Birmingham Railway with that load, nearly approach those on the Great Western of a less power than the North Star, but of a greater power than the London and Birmingham engines. With a load of 50 tons, the North Star engine on the Great Western Railway, acomplished a mean velocity of about two miles an hour greater; the Æolus engine the same rate; but the Venus, Neptune, and Apollo engines, of the same power as those on the London and Birmingham Railway, do not come up to the performances of the latter engines by six miles an hour.

We see likewise in the comparison of these performances a much greater consumption of coke per ton per mile, by the engines on the Great Western Railway, than by the engines on the London and Birmingham Railway; and the construction of the engines being nearly the same, we consequently find a proportionate quantity of water, or quantity of steam, consumed. It is scarcely necessary to say, that the quantity of water used, or weight of steam employed, in a given distance, is a correct test of the power expended in performing a certain quantity of work on that stage; we can, therefore, besides knowing the relative dimensions of the engines, apply this as a test of the power employed by the engines on the respective railways in the performance of a similar quantity of work. Adopting the mode of estimating the relative powers of the engines by a well-known rule, viz., that the power of evaporation by the action of the radiant heat of the fire-box, is three times that of the communicative heat of the tubes; the following table will show the relative powers of the several engines on which experiments have been made, according to this mode of calculation, to which I have added the actual powers exhibited by the experiments, as determined by the quantity of water evaporated into steam.

TABLE V.

THE RELATIVE POWERS OF THE ENGINES ON THE GREAT WESTERN, AND LONDON AND BIRMINGHAM RAILWAYS.

NAMES OF ENGINES	Estimated Powers of Evaporation			Cubic feet of Water evaporated per hour.	Mean rate of speed with Trains of 50 tons in miles per hour.	Consumption of Coke in lbs. per tons, per mile of goods.	Comparative powers and Consumption of Coke.		
	Area of Fire Box Square Feet	Area of Tubes. Square Feet.	Aggregate estimated powers of evaporation				Estimated powers of Evaporation.	Actual evaporation per experiment.	Consumption of Coke per experiment
North Star...	70.10	654.76	288.28	105.6	34.76	1.02	100.	100.	100.

Venus......									
Neptune....	45.	461.51	198.84	106.2	26.57	.69	68.97	64.13	68.86
Apollo.....									
HarveyCombe	50.72	332.45	163.87	94.85	32.4	.59	56.84	57.98	58.88
Bury's Engine	39.2	378.2	165.26	92.74	32.04	.58	57.32	56.	57.88

We see by the above table, the comparative amount of power required to perform the same quantity of work on the Great Western, and on the London and Birmingham Railways; arising partly from the much greater power and weight of the engines, compared with the useful load on the former than on the latter railway, and partly, as will hereafter be seen, on the increased resistance offered by the rails and carriages.

On examining the account of the experiments on the London and Birmingham Railway, it will be seen that, although the mean rate of speed is 32 miles an hour, occasionally on some parts of the line the velocity was much greater, the maximum being 40.9 miles an hour. I shall, for the present, defer making any further comparison of these results, and shall now offer to your notice some experiments made on other railways, as corroborative of the above.

Through the kindness of my friend Mr. Booth, secretary to the Liverpool and Manchester Railway, I have been enabled to make some experiments on deflexion on that railway; and the resident engineer, Mr. Edward Woods, has furnished me with some experiments on the powers of the engines on that railroad.

TABLE VI.

SUMMARY OF EXPERIMENTS ON THE LIVERPOOL AND MANCHESTER RAILWAY.

Planet and Lightning....	26.	16.4	42.4	29.1	747	957	.687

Having been informed, that several experiments had been made on the Grand Junction Railway, on the consumption of coke, and some portions of that Line being particularly favourable with respect to gradients, for experiments on the friction of the carriages; I made application to Mr. Moss, the Chairman of the Directors, for permission to make some experiments on that railway, and received from that gentleman a letter, stating that he had laid my application before the Board of Directors, and that they had authorized him to say that they had much pleasure in meeting my wishes, leaving the arrangement in the hands of their engineer, Mr. Locke.

On applying to Mr. Locke, he at once placed in my hands the result and particulars of a most valuable set of experiments, made on the Grand Junction Railway, and met me on the spot to arrange about any other experiments which I might think advisable to make.

The following are the experiments made on the Grand Junction Railway on the consumption of coke of the locomotive engines.

These experiments are presented for a different purpose than the preceding ones, the former gives the consumption of coke and powers of the engines, with respect to speed, from the time of starting at one end of a stage until they arrived at the end of that stage, or the consumption and rate of travelling during the time of performing the journey alone. The experiments on the Grand Junction line gives the consumption of coke, from the time of lighting the fire until the engine has finished the journey, including all the waste at each end; or, in fact, showing what is equivalent to the consumption in the regular working of the railway, from the time the fire is lighted until the engine has finished the day's work.

Table VII. is the result of these experiments:—

TABLE VII.

The experiments were made for the purpose of ascertaining the comparative qualities of the different descriptions of coke, and were consequently made with the greatest care by Mr. Alcard, the resident engineer.

For the purpose of comparing this result, with that of the consumption of coke of the engines on the Great Western Railway, I have made out Table VIII., from documents furnished me by Mr. Saunders.

We see therefore, that these statements corroborate the result of the former experiments made in a different manner, and show, for the reasons previously explained, a greater expenditure of power, or consumption of coke, on the Great Western Railway, than on the Grand Junction Railway, for the performance of the same quantity of work.

On a careful consideration of the data furnished by these experiments, the conclusions which appear to result from them, as regards the first proposition, viz., the attainment of speed, &c., &c., appear to be as follows:—

1st. That the extreme rate of speed, accomplished on the Great Western Railway, has been 45 miles an hour, with the North Star engine, and with a load of fifty tons, for a short distance.

TABLE VIII.

CONSUMPTION OF COKE ON THE GREAT WESTERN RAILWAY.

166	24.	.306	104	23	.30

We come now to the determination of the first section of the report, viz.: —the question of the attainment of a higher rate of speed, on the Great Western Railway than on other railways, whether the increased width of gauge, is or is not, either necessary, or best adapted for the accomplishment of this speed, and to what extent.

We find, from the results previously enumerated, that a higher rate of speed has been attained on the Great Western Railway, than on other railways. This has been accomplished by the increased power of the engines employed on that railway, above that of those on other railways; before, however, we can determine whether the increased gauge, is or is not, necessary, or best adapted for the accomplishment of this object, and to what extent, we must enquire whether engines of the power by which such performance was effected on the Great Western Railway, or such a power of engine as would accomplish that rate of speed, can be applied on railways of the ordinary width.

The estimated powers of evaporation, of the largest of the engines on the Great Western Railway, is 288.28, as per table; and this engine performs a mean rate of speed with 50 tons, of 35 miles an hour. The evaporating power of the Harvey Combe engine is, by the same table, 163.87, and this engine performs a mean rate of speed of 32 miles an hour. The largest engines manufactured by Messrs. R. Stephenson and Co., and in use upon the Newcastle and Carlisle Railway, have, however, an evaporating power of 253.21; and an engine, built by the same manufacturers, for the Leicester and Swannington Railway, has an evaporating power of 263.8. The Æolus engine on the Great Western Railway, which is the next powerful engine on that line, has an evaporating power of 228.09, and this engine effects a mean rate of speed of 32 miles an hour, with 50 tons.

We see, therefore, that there are engines in use upon Railways of the ordinary width, more powerful, in the proportion of 263 : 228, than an engine upon the Great Western Railway, which effects a rate of speed, within three miles an hour, of the most powerful engine on that railway. We have had no opportunity of subjecting these more powerful engines, on ordinary railways, to experiment, which would have been very desirable on the present occasion; but we find such engines with an evaporating power of 165.26 effecting the same rate of speed on those railways, as the engine of 228.09 on the Great Western; and therefore the presumption is, that engines on railways of the lesser width of gauge, of the evaporating power of 253.21, or 263.8, would effect an increased velocity, quite equal, if not greater, than that of the largest engine on the Great Western Railway.

This conclusion results from the engines on the ordinary railways, yielding a greater comparative useful effect than the engines on the Great Western Railway; partly owing to the much greater disproportion between the weight and power of the engines, and the useful load on the latter than on the former; and partly owing to the increased resistance of the road, and also of the carriages themselves. Those parts only of the increased resistance, however, which relate to the additional strength and weight of the engines, and carriages, and which is produced by the enlarged wind scare of the carriages, are attributable to the wide gauge. We shall afterwards see, how much of the increased power, on the Great Western Railway, exhibited by the preceding experiments, as being necessary to drag the same quantity of goods, at the same rate of speed, beyond that on railways of the ordinary width, is to be placed against the width of gauge; the inference which appears to me to result from these experiments is, that with engines of the same power, a greater result, and consequently a greater rate of speed, may be realised on the ordinary width, than upon the increased width of gauge of railway. If the object be to accomplish the greatest possible speed, a wide gauge is unquestionably better adapted for the construction of the largest possible engines, than the narrow gauge; considerable doubts may, however, be entertained if a gauge of seven feet is the best for this purpose, and whether a less width of gauge, taking into consideration every circumstance affecting the question, would not afford every requisite facility for the erection of engines, capable of attaining a maximum rate of speed.

The question, therefore, whether an increased width of gauge is or is not necessary, depends almost entirely upon the determination of what rate of speed it is advisable to attempt, or it is resolved upon to establish. If a mean rate of 32 miles an hour at full speed be sufficient for the purpose, or such increased rate as engines of the largest dimensions now in use on other railways can accomplish, then it will not be necessary, so far as the motive power is concerned, to increase the width of gauge. But if a greater rate of speed is required, the question assumes a different shape; and it must then be ascertained if an engine can be erected upon the lesser width of gauge to perform that rate of speed.

As this appeared to be a very important part of the inquiry, I asked Mr. Brunel the question as to the rate of speed proposed for both passengers and goods. His answer was:—"The rate of speed proposed I conceive also to be quite uncertain, my own opinion being, that it will always be fixed at the highest which we can maintain with regularity. With moderate loads we might fix it at 35 miles an hour, and shortly, when the road is in complete repair, and kept cleaner, when the short trains are established, so as to render one stopping unnecessary, and our engineers more experienced in the management of the engines, at higher speeds, I think we may attain 38 to 40 miles."

If the object be the attainment of the rate of speed assigned by Mr. Brunel, the present engines, it will be seen by these experiments, cannot accomplish that performance, including all the vicissitudes of weather and other casualties; and, therefore, if a mean rate of speed of 40 miles an hour, including stops, is to be attempted, more powerful engines will be required.

These experiments, however, show the immense sacrifice of power incidental to an extreme high rate of speed, or the accomplishment of a rate of 38 or 40 miles an hour, above that of 32 or 35 miles. If economy of conveyance is to be taken into consideration, it becomes a serious question whether such a system should be acted upon as that of providing for an indefinite rate of speed, or that a maximum rate should not be determined upon, and that such standard should be composed of that speed which will best suit the public conveyance generally, and at the same time comprehend every possible economy and regularity. It is, however, not necessary to enter further upon this at present, as the determination will be influenced to a certain extent by other facts elicited in the course of this inquiry, and which, in my opinion, leads to the conclusion that the limit of practical speed, combined with the requisite economy, is that which can be attained by engines capable of being erected on a lesser width of gauge than seven feet.

The preceding experiments having been made for the purpose of ascertaining the comparative power required to work the trains upon the Great Western road, contrasted with the power required to work trains on railways of the ordinary width and construction,—and were quite necessary, in a practical point of view, to show the comparative aggregate amount of effective power given to the load by the engines at present employed on that line, and the effective power produced by the engines on other railways. But these experiments, however extensive and valuable, do not determine the whole question, for although they show the amount of power required to work the respective railways, yet that power is employed to overcome the aggregate resistance of the engines, the friction of the carriages, and the resistance of the road; it became, therefore, extremely desirable that we should separate the results, to arrive at practical conclusions, by which to make a comparison between the two systems of an increased and ordinary gauge of railways.

If the object had been only to ascertain and develope the power required to work the Great Western Railway, this would have been shown by these experiments, and it would have been less an object of utility to determine what part of that power was expended in overcoming the resistance of the engines, what part was due to the friction and resistances of the carriages, and what amount of obstruction was caused by the road. But when the inquiry was extended to a comparison with other railways, it then became necessary to separate the results, the engines employed on the Great Western Railway being, in some respects, different from those employed on other railways; the carriages are also different, and the construction of the road varying likewise.

The carriages on the Great Western Railway are mounted on wheels four feet diameter, whereas the wheels of the carriages on the other railways are generally, and those on which the experiments were made were upon wheels three feet diameter. The first inquiry, therefore, appeared to be to determine the comparative friction of four feet and three feet wheels, or wheels of different diameters.

Again, the experiments with the trains included the resistance opposed to the carriages and engines by the road, and the construction of the rails being different from those on which the other experiments were made, it became necessary to determine what effect the peculiar construction of the road had upon the aggregate resistance determined by these experiments, and to ascertain the comparative friction of a road with continuous bearings and piles and a road upon isolated supports, or such as those on which the several experiments were made.

These investigations, therefore, comprise the second proposition, viz.:— The mechanical advantage or diminution of friction, by being enabled to increase the diameter of the wheels without raising the bodies of the carriages, and in what respect, and to what extent the friction of the carriages is affected by the peculiar construction of the road. The first process will, therefore, be to determine the actual friction or resistance of the carriages on the respective railways. Many modes have been adopted by different experimentalists, of determining this on railroads; that of variously constructed dynamometers, the force of gravity, and several other modes.

The action of the dynamometers is so very irregular, requires such perfect instruments, and even with the utmost possible care it is extremely difficult to ascertain the correct resistance; the vernier in a state of constant vibration or oscillation, that no correct mean result can be determined by observation. I had a dynamometer constructed in 1835, which was mounted on a truck, and, by a set of rollers connected with the travelling wheels, unwound a roll of paper, upon which the vibrations of the vernier was traced by a pencil. By this mode of application the real vibrations of the vernier was recorded, in a precisely similar manner to that which will hereafter be shown to have been used in these experiments to record the motion of the carriages, and by which a mean result can at any time be obtained by admeasurement of the diagram. This machine being, however, constructed for a 56 inch gauge of railway, and being rather cumbrous and bulky, could not be adapted to the Great Western Railway in time for the purpose of this inquiry, and this instrument is likewise liable to the objection of all dynamometers; that being placed behind the tender, they do not show the entire resistance of the train, the tender intercepting the effect of the atmosphere, and diminishing, therefore, the entire resistance.

The gradients of the Great Western Railway also, being nearly that of a level, the action of gravity could not be made use of for determining the friction; and therefore there appeared no other mode than the following, by which the resistance could with any degree of accuracy be determined:—

A piece of road, perfectly straight, and as nearly level as could be obtained, was selected; this road was staked out with posts at every 110 yards. An engine and train of carriages, the friction of which was to be ascertained, was brought to one end of the stage so staked off; the steam was set on, and the engine and train put in motion, until they acquired a velocity of about 20 miles an hour; the steam was then shut off, the engine stopped, and the train of carriages being previously detached from the engine, they were allowed to run along the line until the friction and resistance of the atmosphere brought them to rest; during the whole of the experiment, the time of passing each post was carefully noted down, and also the time when the carriages came to rest.

Note P, Appendix, is an account of the experiments and formulæ, for ascertaining the comparative friction of three and four feet wheels on the Great Western Railway.

Note Q, the experiments made on that and other railways, for the purpose of ascertaining the comparative resistance of railway trains.

These experiments were made at a velocity, at the commencement of the experiment, not exceeding 20 miles an hour, and varying from that until the carriages came to rest; and appeared to be the only mode of obtaining the friction by a precisely similar manner on the Great Western and other railways. The resistance of the most important section of the experiments with the engines are not, however, comprised within the rate of speed at which the preceding experiments with the engines were made. We have already remarked the very great diminution of effect at a high rate of speed, especially when a velocity of from 35 to 40 miles an hour was attained; it became, therefore, of the utmost importance to ascertain whether the diminution of effect was referable to the engines, or to the resistance of the carriages at those higher rates of speed.

The chief part of the resistance to which practical attention has been directed is that which is properly called *friction*. That the atmosphere offered some resistance has been always, of course, admitted, but this resistance has been generally considered to be so insignificant, compared with the resistance depending on friction, that in all calculations which have come within my knowledge it has been wholly disregarded.

It became, however, of the greatest importance to investigate, to the fullest extent, every resistance offered to the motion of railway trains, especially at high rates of speed, and it was therefore determined to institute a course of experiments, with a view to determine, by some direct and conclusive means, the actual amount of atmospheric resistance, independently of any principles of calculation founded upon the laws of friction.

The method adopted was founded upon the following considerations:—By numerous experiments which have been made by different philosophers on the resistance of the air, it has been satisfactorily ascertained that that resistance varies in a proportion somewhat higher than that of the square of the velocity of the moving body. Whatever, therefore, might be the actual amount of this resistance, at any particular speed, it was to be expected that its increase would be very rapid, even by a small increase of speed. If, therefore, a railway train was moved down an inclined plane, of an inclination so steep that gravity would produce considerable acceleration of motion, the resistance of the motion, so far as that resistance depends on the air, would be subject to a rapid increase. Now, if the resistance of the atmosphere be considerable, it is quite clear that the speed which the train would acquire in descending the inclination might be such as to render that resistance so great that, combined with the friction, it would be in equilibrium with the gravitation of the train down the inclination; and in such case the necessary consequence would be, that the train would cease to be accelerated, that it would require an uniform speed in the descent, which it would retain without any augmentation until its arrival at the foot of the plane.

The Whiston inclined plane on the Liverpool and Manchester Railway being straight and about a mile and a half in length, falling at the rate of 1 in 96, afforded a favourable opportunity for the experimental test. A train of four first class carriages was accordingly prepared and brought to the level at the summit of this inclination. In the first instance the carriages were not loaded, save by the persons employed in making the observations, and the gross weight of the train was 15, 6-10th tons. An engine was placed behind them, so as to push them towards the summit of the plane, and then to dismiss them down it with a considerable speed. They commenced the descent accordingly, moving 100 yards in seven seconds, or nearly 30 miles an hour. As was expected, a uniform speed was soon acquired, which suffered no change until the arrival of the train at the foot of the plane; this uniform speed in the first experiment was 45 feet per second. The experiment was repeated in the same manner, when a uniform speed was again attained of 46, 3-tenths feet per second, the mean speed in these two experiments being 45, 6-10ths feet per second, or about 31 miles an hour. The carriages were now loaded with a weight equivalent to their usual load of passengers, by which the gross weight of the train was increased to 16 tons 1 cwt.; the gravitation of the train being thus increased it was expected that the speed would also increase, the momentum of the descending body being adequate to encounter a proportionally greater resistance of the air. Three experiments were then made with the trains thus loaded, which showed results of considerable uniformity; in the first experiment the uniform speed attained was 46, 8-10ths feet per second; in the second, 48 feet; and in the third, 47 1-10th feet per second, the mean of which is 47, 3-10ths feet per second, or 32¼ miles an hour.

The force exerted by 15, 6-10ths tons down an inclination of 1 in 96 is equivalent to 364 pounds, and as this was the weight of the train in the first experiments, it follows that such a coach train moving at 31 miles an hour suffers a resistance of that amount, which includes both friction and atmospheric resistance.

Again, the force exerted by 16 ton 1 cwt. down the same inclination is 421.12 pounds, and as the train having this weight moved with a uniform velocity of 32¼ miles an hour down the plane, this was its resistance at that speed.

These experiments are quite conclusive as to the agency of the atmosphere, in resisting the motion of trains on railways. It has never been pretended that the actual resistance from friction amounts to more than nine pounds a ton of the load, and many have stated that it does not exceed seven pounds, and some that it is so low as six pounds. But even if the highest of these estimates be taken, it would follow that the whole of the resistance of 421 pounds, encountered by the train moving at 32¼ miles an hour, only 162 pounds are due to friction, while about 260 pounds are due to the atmosphere. But we shall presently show that this estimate of the resistance from friction is overrated, and that, therefore the amount of the atmospheric resistance here referred to is considerably underrated.

In comparing the results of these two sets of experiments, it will be apparent in how great a degree the resistance is increased even by a small increase of speed. The mean speed in the first two experiments was 13 miles an hour, and in the last three 32¼; the ratio of these velocities is about 100 to 103, the speed being in the latter case increased three per cent. Now the resistances in the two cases were in the direct ratio of the gross weight of the trains, which ratio was 100 to 115. Thus to gain an increase of speed amounting to 3 per cent., an expenditure of power amounting to 15 per cent, is necessary. Nor can it be said, that the great amount of resistance here manifested was produced by a head wind, though even were such admitted to be the case, such an admission would equally involve the principle of a powerful atmospheric resistance; but in fact, in all the experiments performed upon this plane, there was a pretty strong wind directly in favour of the motion of the train down the plane.

Scientific experiments shew, that the increase of resistance from the atmosphere is in a higher ratio than that of the square of the velocity; the experiments just mentioned confirm this, for while the squares of the velocities increase in the ratio of 100 to 107, or 7 per cent., the resistance is increased in the ratio of 100 to 115, or 15 per cent.

These experiments, though conclusive as regarded the effect of the atmosphere in this case, and though they give a total amount of resistance, were insufficient to determine the proportion in which this resistance was due to the atmosphere, and to friction. Various methods of determining this presented themselves. If a train were moved down an inclined plane commencing from a state of rest, or with any given speed, and allowed to be gradually accelerated, subject to the combined resistances of friction and the atmosphere; the circumstances of its motion could be investigated by the principles of mathematics, assuming that the friction was, as it is generally considered to be, independent of the velocity, and that the atmosphere varies either as the square, or as any other assumed power of the speed. This, however, comprehended complicated problems, and it therefore became desirable that some more direct method of deriving the required quantities should be adopted, and if possible by direct experiment. By subjecting to experiment the same or similar trains down different inclinations, different velocities would be attained, and these velocities would balance the different resistances due to such inclinations, and distinct data would be thus obtained, which being properly combined and compared, would show the friction and the atmospheric resistance separately. It was difficult, however, to find inclined planes precisely suited to this purpose, and the following experiments, combined with those on the Whiston Plane, were made for the purpose.

An inclined plane occurs on the Grand Junction Railway, descending from Madeley towards Crewe, the inclination of which is 1 in 177; four carriages were selected, and loaded so as to render the gross load equal to that of the four carriages with which the last three experiments were made on the Whiston Plane,—that is, their gross load amounted to 18 tons 1 cwt. These carriages were propelled by an engine to the summit of the Madeley Plane, and descended down it in the same manner, as was done with the carriages in the former experiments on the Whiston Plane. A uniform speed was in like manner obtained, which continued to the foot of the plane. In the first experiment this speed was 30, 4-10ths feet per second, and in the second 31, 4-10ths feet per second; the mean of the two being 30, 9-10ths feet per second, or 21 miles an hour. The force of 18 tons 1 cwt. down this plane being 228·4 lbs. it follows that this represents the resistance of such a train moving at 21 miles an hour. From this and the experiments down the Whiston Plane, two distinct data were obtained for the total resistance, including atmosphere and friction, viz. at 32½ miles an hour, the sum of the resistances was 421 lbs., and at 21 miles an hour it was 228½ lbs. By combining these results, a simple mathematical process gives us the resistance due to friction equal to one 433rd part of the weight, or 5·17 lbs. per ton; hence the total resistance due to friction for the coach train used in these experiments was 93½ lbs. and therefore the resistance due to the atmosphere moving at 32½ miles an hour was 329 lbs., and at 21 miles an hour 135 lbs.

From these experiments, therefore, it follows, that of the whole resistance which the moving power had to encounter in these experiments, when a speed of about 32 miles an hour is maintained, 22 per cent. only is due to friction, while 78 per cent. is due to atmospheric resistance.

Having thus ascertained that a comparatively small proportion of the whole resistance is due to friction, it ceased to be a matter of surprise that the methods of calculating the resistance of trains, based exclusively on the laws of friction, should give discordant and unsatisfactory results. Yet such methods are the only ones which appear to have been hitherto applied to this enquiry. By such methods the common estimates of from 7 to 9 pounds a ton from friction have been obtained, and as such estimates have been derived from carriages in motion, and without any allowance for atmospheric resistance, it is obvious that to whatever extent that resistance may have affected the calculations, to the same extent has the estimate of friction derived from them been augmented beyond the truth; and this will satisfactorily account for the amount of friction derived from the above calculations, which are independent of atmospheric resistance, being so considerably under the common estimate.

These comparative results were, however, obtained from one set of experiments only on each plane; and although they determine most conclusively, that a very considerable resistance arises from the effect of the atmosphere; yet I would not have it understood that the amount of friction, properly so called, as determined by these experiments, should be adopted as a standard; there can be no doubt that its precise amount is much less than the received opinion, but it would require further experiments, more in number, and more varied, to determine the amounts which should be adopted as a standard at different velocities and with different weight of trains.

The experiments on the comparative friction of the four and three feet wheels, and also those made to ascertain the resistance of the road, having been made by putting the carriages into considerable velocity, and allowing them to come to rest, the velocity was therefore variable, from the extreme motion to rest. As the atmospheric resistance varies as the square of the velocity, while the friction of attrition on the axles, and the resistance of the wheels on the rails are constant at all velocities it requires a complicated formula for calculating the amount of each separately, and it requires also a series of experiments to come to a correct conclusion.

As, however, that part of the resistance of carriages which depends upon the increase of the diameter of the wheels, has been, by the preceding experiment proved to be so extremely small in proportion to the entire resistance; and as the experiments with the three and four feet wheels were made upon waggons, (there not being both descriptions of wheel upon the passengers' carriages), I did not think it advisable to give results deduced from complicated formula, in this report; they are, however, given in the Appendix, Note S, together with the formula by Dr. Lardner, for calculating the resistance.

There can be no doubt, that the friction on the axles, and also the resistance of the wheels on the rails, will be diminished in the ratio of the diameter of the wheels; but on the other hand, if large wheels have the effect of presenting an increased frontage to the carriages, it is doubtful to what extent they are productive of a diminution of resistance, at high rates of speed:—with heavy loads at a slow rate of speed, there is no doubt that a reduction of friction will be effected by them, but our enquiries are with high rates of speed, and, therefore, until further experiments are made, it cannot be determined what the effect will be by an increase of diameter of the wheels.

The above reasons, likewise, preclude us from determining with perfect accuracy, the relative resistance of the Great Western rails, and those of other railways; the mode of conducting the experiments being the same as above stated, viz. of putting the carriages in motion and running them to rest. The atmospheric resistance being affected by a difference of the area of frontage of the carriages, and the carriages on railways of a narrow width having a less frontage than those of the Great Western, unless we could determine what effect the increased frontage had at all the varying velocities, we could not determine that part of the resistance which arises from the wheels upon the rails.

This is, indeed, more difficult than that of determining the relative resistance of wheels of different diameters, the experiments in the latter case, being made with carriages of the same construction, whereas in the former case, they made with carriages of a different construction.

It will be afterwards seen, that the rails of the Great Western Railway present a less rigid surface to the wheels than stone blocks, but about the same or rather less than wooden cross sleepers; and as it may be presumed, every other circumstance remaining the same, that the resistance opposed to the rolling of the wheels upon railroad, will be in some degree proportionate to the rigidity of the surface on which they roll, especially when the material composing the surface is the same; we may, therefore, conclude that the resistance opposed to the carriage wheels upon the Great Western Railway, will be about the same as that of a railway laid with cross sleepers, but greater than one constructed with stone blocks:—to what extent the present question is affected by this, will be afterwards considered.

We come now to the first part of the third proposition, viz. The comparative advantage, or firmness of base or road track, of the Great Western Railway, constructed with continuous timber bearings, with or without piles.

The only mode by which this could be determined in a satisfactory manner, appeared to me to be by direct experiment, by ascertaining the extent of deflection produced on the rails of the Great Western Railway by the passage of trains of known weights along them; and by making similar experiments on other railways differently constructed, thus to determine which of them were least affected by the passage of the load.

In an enquiry in 1835, as to the best description of rails and fastenings for the Liverpool and Manchester Railway, by Professor Barlow, he employed an instrument which he called a Deflectometer, to test the amount of deflection produced by the passage of the trains along rails of different descriptions. This instrument, however, only recorded the extreme or maximum deflection, and as in many cases jerks were produced by the lurching of the engine and carriages, which threw the vernier of the instrument upwards in a very distorted manner, the result was by no means so satisfactory as could be wished. He likewise only employed one instrument, consequently the observed deflections in the middle of the rail, being affected by the depression of the blocks supporting each end, the entire effect was not shewn.

It occurred to me that by improving the form of this instrument, and by applying the same apparatus which has been previously described as being used for the dynamometer, the motion of the arm of the deflectometer, or instrument showing the deflection of the rails, might be recorded, and we should then obtain a diagram of the deflections of the rails as the trains passed over them; and by employing three instruments at the same time, one at each point of bearing at the blocks, (or transoms of the continuous rails,) and one midway between the transoms, or in the middle of the rail, and having all these connected together, so as to record their action at the same time, we thus obtain correct diagrams of the deflections produced at each of these points as the train passes over.

By this plan we not only had produced diagrams, showing the actual amount of deflection of the rails and bearings; but we had exhibited upon paper, the nature of the action of the deflection produced, and consequently a correct outline of the effect of the passage of the trains on rails of different kinds.

On considering the subject of the deflection produced by the passage of the trains on a railroad, it will be readily conceived that the deflection vertically is not the only effect; if the rails are not perfectly perpendicular, and the rim of the wheel perfectly cylindrical, which in practice is seldom or ever the case; or, if the base of the block or timber bearing be not perfectly horizontal, supporting the load with equal firmness throughout the whole area of its base; when the incumbent weight comes upon the rail, there will be a certain extent of deflection horizontally, as well as vertically. On almost all railroads the periphery of the wheel is conical, and the rails are laid at such an angle as to correspond with the cone of the wheels; the line of pressure of the incumbent weight is not therefore vertical, but in a line at right angles to the cone of the wheel, and has of course a tendency to produce horizontal deflection, and this will also be further increased when the flanch of the wheel presses against the rail. The combined action of all these effects will be, a certain amount of deflection in the direction of the resultant of the several forces, considered in connection with the position of the base whereon the blocks or sleepers ultimately rest. The direction of the combined action of the incumbent weight upon so yielding a base, and liable to be affected by so many circumstances; must, it may be supposed, vary in almost every case, and, therefore, no instrument could be so placed as to indicate the resultant effect of these various motions.

The only mode of determining this appeared to be, the application of an instrument to measure the extent of horizontal deflection, in addition to that of the vertical deflection, when it will at once be seen that the two motions could be resolved into their resultant.

In a practical point of view, independently of being able to resolve the two motions into one, it appeared desirable to know the amount of horizontal, or lateral deflection, as well as that of vertical; a particular plan of construction of railway might exhibit very perfect results, as regarded the amount of vertical deflection, and yet be very inferior, as regarded the lateral motion, or horizontal deflection, and vice versa; the investigation could not, therefore, be complete without having developed the extent of each description of motion.

The mode of conducting the experiments was as follows:—

These instruments were first of all applied to the rails of the Great Western Railway, one instrument being placed opposite a single transom, another instrument opposite a double transom, and the third midway between the transoms. The trains were then run along the rails, at first with a slow motion and diagrams taken, the motion was gradually increased, and diagrams were again taken; several diagrams were thus taken at different parts of the line, with the rails in their working state. The piles were then detached from the transoms, by withdrawing the bolts, and diagrams taken in the same manner; next, the transoms were cut asunder, thereby allowing the longitudinal timbers to act independent of any support from the transoms or piles; and in some experiments, after the transoms were detached from the piles, they were cut asunder between the two lines of way, when they acted as cross sleepers between the timbers without piles, diagrams being taken in all these variety of cases.

The instruments were not, however, always placed in the positions above stated, they were varied, both as regarded the places where joints of the iron rails occurred, and also with respect to the joints of the timbers, as regarded their position with the joint of the rails. The experiments were likewise made on embankments and in cuttings; and also on the longitudinal timbers where no piles existed.

It was also found to be desirable to ascertain if any motion of the rail upon the timbers existed, and consequently diagrams were taken by applying the instruments successively to the rail, and to the timbers.

The next set of experiments were made upon the London and Birmingham Railyway, two of the instruments were here placed as near the chairs or points of support as possible, and the other midway between them. Diagrams were taken on 50lb. and 62lb. rails respectively; but the vertical deflection only, was taken on this railway, and on stone blocks.

Experiments were likewise made with the same instruments, on the Liverpool and Manchester Railway, of both horizontal and vertical deflection, on 60lb. rails with four feet bearings, and 75lb. rails with five feet bearings.

A more extended course of experiments were made on the Grand Junction Railway; on this line all the rails are of one weight and section, but they are placed in some parts of the road on stone blocks, on other parts of the line on cross wooden sleepers, and upon the Dutton Viaduct on longitudinal timbers. Diagrams were taken at varying rates of speed, of both horizontal and vertical deflection of rails supported by stone blocks, wooden cross sleepers, and longitudinal timber bearings respectively: the instruments were then applied to the chairs, and diagrams of the deflections of these taken, and lastly, they were applied to the blocks, sleepers, and timbers respectively, and diagrams taken of the depression produced by the passage of the trains on these different description of bearings.

The next railway on which experiments were made, was the Manchester, Bolton, and Bury; this railway is constructed partly of continuous stone blocks, but mostly of continuous timber bearings, with cross timber ties, or transoms, and without piles. It became, therefore, an object of great interest to ascertain the comparative effect upon the road by the passage of the trains, over continnous bearings on this line without piles, and on the Great Western Railway with piles. Experiments were therefore made, in every respect the same as those on the Great Western Railway, the instruments being applied successively to the rails and timbers, Upon the stone bearings resting upon masonry there was in fact no depression or yielding whatever, and therefore these diagrams, though taken, are not given in the book.

The following tables will show the vertical and horizontal deflection of the rails and timbers in the several varieties of application of the instruments, on the Great Western and other railways in parts of an inch:—

On an attentive examination of the results of these experiments, as exhibited by the preceding tables, but more particularly on examining the diagrams themselves, and the measurement of each, it will be seen that stone blocks (except in some cases where they were not properly seated), afford decidedly the firmest, and most unyielding base; that there is not much difference in the firmness of base between cross timber bearings, and continuous timber bearings without piles, as exhibited on the Grand Junction, and Manchester, Bolton and Bury Railways; but that there is a greater variety in the results of the different experiments in cross sleepers than in continuous bearings.

It will likewise be seen, that on isolated supports there is a greater amount of deflection shown in the rails than in the chairs; and still less deflection in the blocks and wooden sleepers than either the chairs or rails. The inference from this is, that the rails in these cases were not firmly fixed down to the chairs; and also that the chairs were not immoveably secured to the blocks and sleepers; and as the experiments comprehend a great many cases, it may be presumed that such is the case generally on isolated bearings.

On the Manchester and Bolton Railway, the joints of the rails rest on flat chairs, the rails being on either parts of their length fixed to the timber bearings with iron clamps; here also we find a considerable yielding of the rails upon the timbers, the latter showing less deflection than when the instruments were applied to the rails.

The experiments on the Great Western Railway, shew in the tables a less difference of deflection between the rails and the timbers, than any of the modes of fastening either on isolated supports or on the continuous bearings of the Manchester and Bolton Railway; and hence we may conclude, that the mode of fastening the rails to the timbers on that railway by screws, effects a firmer junction than any of the other modes of fastening. On examining the table it will be seen that notwithstanding the assistance of the piles, the diagrams show a greater amount of deflection of the timber bearings of the Great Western Railway than the stone blocks, and quite as much as the continuous bearings without piles; the firmness of base as shown by these experiments, is, therefore, less than with stone blocks, and not greater than with continuous bearings, without piles, but less than cross isolated timber bearings. It must, however, be remarked, that these tables show the deflection on the Great Western Railway, with engines and carriages much heavier than those used in taking the deflections on the other railways of the ordinary width; and although they exhibit the comparative deflections produced by the passage of the trains, according to the respective systems of working the railways at present in use, and which may be considered as the practical result of the effect of the trains on the rails; still, if we wish to know the actual comparative firmness of base, we must take into account the relative incumbent weights of the respective trains. I have not yet been able to obtain the pressure upon the rails of the Great Western Railway by the engines, there being no weighing machines on that railroad by which this could be ascertained, when these weights are known, the comparison can then be made with the engines; the weight of the carriages are known, and the comparison can therefore be made with them. The weight on each wheel of the Great Western Railway carriages may be taken at about 1·5 tons, and of the carriages on the other railways at 1·125 tons; and consequently the deflections have been produced with incumbent weights, in the proportion of 4 : 3.

We come now to the effect which the piles have upon the firmness of base of the continuous timbers on the Great Western Railway; the reasons assigned by Mr. Brunel for adopting piles was, for the purpose of securing and holding the timbers down to the ground with much greater force than merely the weight of the timber itself, and thereby to effect a closer contact between the timber and the ground. It became, therefore, necessary to ascertain whether the timbers were held down to the ground, or if they were supported by the piles. To accomplish this, the instruments were first of all applied to the rails with the piles in action, or without being disturbed, and the deflections taken; the transoms were then divided near to the timbers, or between the timbers and the piles, the instruments remaining applied to the rails, and the effect produced by the separation of the timbers from the transoms was thus obtained; in almost all, if not in every case, the timbers fell, on the transoms being divided, showing that the action of the piles was not to hold down, but to support the timbers. This was also shown very conclusively in the effect exhibited by the diagrams taken, before and after the transoms were divided; —the first diagram taken after the transoms were divided, showed a greater amount of deflection from the original line of the rails, than when the piles were in action; it was found, however, that the rails did not rise to their original level, but that, in fact, a permanent depression to a certain extent had taken place;—in continuing the experiments the deflection became less, showing quite decisively, that the timbers were supported by the piles, and that they were not in fact in such close contact with the ground when attached to, as they were after being detached from, the piles. This was the result in every instance. Most of the diagrams were taken upon that part of the line near to Paddington which had been recently packed, and being clayey ground presented a wet and spongy base, and the packing was not so perfect as in some other parts of the line; the extent of the deflections on this part should therefore be taken as being more unfavourable than an average result; but on applying the instruments to a part of the line, selected as being in the best order, the same relative results were exhibited; the timbers dropped on their division from the transoms and piles, and it was found that the amount of deflection was less after the piles were detached than before, after the train had run along the rails for a few times.

Some part of the Great Western Railway is laid with continuous timbers, without piles; an experiment was made upon this, where the ground was not the most favourable, or similar to that where the diagrams were generally taken with piles, and deflections similar to the above were obtained;—an experiment was however made, and several diagrams taken, upon an embankment with timbers without piles; when the result was an amount of deflection much less than that where the piles were in action, and very little, if at all, inferior to that of stone blocks, taking into account the difference of the insistent weight. At this place, however, the scantling of the timbers was greater than ordinary, being ten inches in depth, the general depth being six to seven inches.

The experiments on the Manchester and Bolton Railway, it will be seen, exhibit a considerable amount of deflection, quite as much, if not greater, than that of the Great Western generally, taking into account every circumstance of the scantling of timbers, section of rails, and weight of the engine and trains.

The result of the whole of these experiments is, that stone blocks afford the firmest base; and that there does not exist any material difference of deflection between longitudinal timber bearings with a continuous rail, and cross timbers with isolated supports; the difference, if any, being in favour of continuous bearings.

The previous observations apply to the vertical deflection only, during the progress of the experiments on all rails resting on chairs, it was found that in a great many cases the rail was deflected inwards, the great majority of cases, however, being outwards; it has been, therefore, extremely difficult to reduce the results into a tabular form, some of the diagrams exhibiting both inward and outward deflection in the same experiment. The cone of the wheel having a tendency to press the rail outwards, and also the action of the flange having the same tendency, it is quite clear that when the deflection is inwards, it must be the result of some accidental cause; a want of solidity of the base of the blocks or sleepers on the inner edge, or from the rail not bearing horizontally in the chair, or at the proper inclination to the cone of the wheels. Upon the Great Western Railway, the horizontal deflection was invariably outwards, and this is no doubt owing to the particular construction of that road admitting of a more perfect and permanent adaptation of the rail to the cone of the wheels. Want of time precludes me from going into the particular results, exhibited by these experiments on horizontal deflection; the general result, however, appears to be, that they assimilate very nearly to the vertical deflections, both in their nature and extent, on the different descriptions of bearings.

The remaining part of this inquiry is the latter part of the third proposition, viz.; whether a greater steadiness and smoothness of motion is produced to the carriages, and to what extent, on the Great Western Railway, by the increased width of gauge.

The solution of this question also appeared capable of being subjected to the test of experiment, although not without considerable difficulty. The motion of carriages on railways being the effect of so many distinct causes, it was extremely difficult to contrive an instrument to detect and record each motion separately.

For instance, any sinking of the blocks, or supports of the rails, or the deflection of the rails themselves, produce a corresponding depression of the wheels of the carriages on that side where such yielding takes place;—the subsidence or shrinking of the base, or formation level of the railway, generally produces also an inequality of level on the two sides of the railway; and these variations of level between one side and the other, tend to produce a continual rocking motion in the carriages transversely, which is aggravated more or less in proportion to the frequency and extent of these inequalities of level of the two sides of the railway. The same causes, viz. the inequalities of level, likewise produces a pitching or undulating motion, longitudinally; and those two motions combined, the undulatory motion in the direction the carriages are travelling, and the rocking motion traversely, produce a vertical motion. Any change likewise in the direction of the road, throws the carriage wheels from a straight line against the interior side of the curve, and thus produces a lateral motion of the carriages, and when the curve again changes, or the line of direction becomes straight, the wheels are thrown to the opposite side of the rails. The difference of level between the rails on the two sides of the railway, besides producing a rocking motion transversely, causes the carriages to vibrate from side to side, in proportion to the extent of the inequality of the level; the depression in the first instance causing the carriages to fall towards that side of the road, and the flanch of the wheel to press against the rail, the conical form of the wheel immediately throws it off towards the opposite side; and we thus have a continual contest between the gravitation occasioned by the difference of level between the two sides of the railway, and the line of direction incidental to the conical action of the wheel:—As these effects are continually in action, we hence find that the lateral oscillatory motion is the most predominant of all the varieties of motion which occur on railways; and when a very high rate of speed is attempted, this lateral motion is very considerably increased, so much so that in extremely high rates of speed a sort of swinging lateral motion is produced, the carriage wheels on each side being thrown alternately back and forwards against the sides of the rails:—probably from the cone of the wheels, not having time, in extremely rapid velocities, to accommodate itself to the proper line of direction.

Considering, therefore, the variety of motions in action at the same time in railway carriages, the different causes by which these are produced, and the numerous adventitious circumstances operating to increase, modify, or counteract them, it is not to be wondered that a difference of opinion should exist in the public mind generally, as to the relative smoothness of motion of railway carriages on different railroads;—an increase of a few miles per hour in the velocity, not perceptible to a traveller, will make a considerable variation in the motion;—the number and nature of the curves;—a difference in the construction of the carriages;—the position of a carriage in the train;—or even different bodies of the same carriage, all tend to influence the aggregate amount of motion in a railway carriage; and few, if any, of the causes whereby these different motions are produced, are sensible to the observation of a passenger, at least to the great majority of passengers; they judge from the quantity of motion, without reference to the causes, and hence the difference of opinion, which has arisen as to the comparative smoothness of motion on some of the existing railways.

To the most attentive observer, knowing all the causes which produce these variety of motions, it would be extremely difficult, if not impossible, to judge from observation of the relative smoothness of motion, or at any rate of that which properly belongs, or has reference to, the construction of the railway.

These circumstances, therefore, rendered it almost absolutely necessary to subject this part of the inquiry to experiment, it not appearing possible to arrive at any conclusive determination by common observation; and after considerable difficulty a set of instruments were contrived, which subjected all the different motions of railway carriages to experiment, and which produced diagrams of all the oscillations of the carriages from one end of the line to the other.

The different kinds of motion produced on railway carriages may therefore be comprised within the following heads, viz.:—

1st. A rocking motion transversely, produced by the inequalities of the level of the two sides of the railway.

2nd. A pitching or vertical motion, in the centre of the carriages, being the combined action of the alternate rocking motion of the two sides of the carriages, produced by the undulations of the road.

3rd. A lateral, or oscillatory motion horizontally, produced also by the inequalities of the road, and the other causes previously enumerated, throwing the carriage wheels from side to side against the rails. * * *

Having thus, agreeably to your instructions, and to the extent to which the time and opportunities afforded has enabled me to accomplish, investigated by experimental data and inquiries all the properties of the system of construction and working of the Great Western Railway, I now beg to lay before you the conclusions which appear to me to be the result of these investigations. I think it my duty however, in this place, to represent to you that I have not been able, in drawing out this report, to avail myself fully of the vast mass of valuable information elicited in the course of this inquiry, owing to the short period, (only six days,) between finishing the experiments and being required that the report should be printed; and I trust that this will be a sufficient excuse for the imperfect manner in which it is presented to your notice; at the same time, I beg to add, that I have in the short period allowed to me, availed myself of every fact or discovery of a practical nature, which appeared to me to bear upon the question, or to be in any way conducive towards your interests. I have, in the appendix, given in detail all the experiments which I thought would be of any utility, and from which, at any subsequent period, the valuable information contained therein may be extracted and investigated; and it occurred to me to be very important that these documents should be given in such a manner and in such detail, that it should be in the power of yourselves or your engineer at any time, to examine into and compare the conclusions which I have arrived at, and which appear to me to result from these experiments, with the experiments and investigations themselves.

Width of Gauge.—Pursuing the same arrangement as set out with in the first part of this report, I shall now consider in what manner, and to what extent, the results of these investigations and experiments bear upon the reasons which induced the adoption of the increased width of gauge, and the particular construction of the Great Western Railway.

The first is the attainment of a high rate of speed. The experiments on the power of the locomotive engines show, that the engines at present employed on the London and Birmingham Railway accomplish an average rate of speed of 32 miles an hour, with weights equal to that of a first-class train, (Table III.); but that engines in the proportion of 263 : 165, more powerful than these, are in existence on the same width of railway. The less powerful engines accomplish a rate of speed within three miles an hour of the most powerful engines on the Great Western Railway, (Table V.); and, therefore, the presumption is, that if the more powerful engines on the ordinary railways had been tried, they would have accomplished a higher average rate of speed than the most powerful engines on the Great Western Railway, the effective power apparently yielded by the former being much greater than the latter. But we now find that a cause exists which perfectly accounts for this comparative diminution of effect, and that it is, in fact, if not almost entirely, attributable to the greater atmospheric frontage of the Great Western Railway carriages, than those upon the London and Birmingham Railway, and the powerful effect which the atmosphere has upon the resistance to be overcome.

The experiments on atmospheric resistance being as yet confined to the carriages of the narrow gauge, we cannot satisfactorily determine what the precise increase of resistance will be by an enlarged frontage; the carriages of the Great Western Railway are 10 feet high from the rails, and 9 feet wide = 90 square feet, whereas the London and Birmingham Railway carriages are only 9 feet high and 6¾ feet wide = 60 square feet; but an open space exists below the wheels, which is only partly filled up by the fire-box of the engine; taking, in each case, a foot from the rails to be clear space, the relative area of frontage will be 81 : 53. Every circumstance being the same, we may suppose that the atmospheric resistance will be as the area of frontage, but the figure of the engine preceding the carriages, the comparative length of the train, and several other circumstances, may affect the result; and, therefore, until the question has been satisfactorily determined by experiment, no comparative standard can be assigned of the relative amount of atmospheric resistance to trains of different areas of frontage.

For these reasons, therefore, I shall not go into an analysis of the presumed resistance of the Great Western trains, as compared with those of the London and Birmingham Railway; for the same reasons, likewise, it will at once appear to be impracticable, with the data we are at present in possession of, to determine with any degree of accuracy the comparative advantage of large and smaller driving wheels to the engines;—the incontrovertible conclusion, that a very large proportion indeed of the resistance of railway trains is attributable to atmospherical resistance, is quite sufficient to account for all the differences of results between the engines on the two descriptions of railways; but to what extent, and what portion is attributable to atmospherical resistance, what part to the engines, and what portion to the carriages, varying as both engines and carriages do, in the diameter of their wheels, cannot be conclusively determined at present.

There can be little doubt that the atmospherical resistance varies at least in the ratio of the square of the velocity; considering, therefore, this rapid increase of resistance, it appears to me, that no other conclusion can result from these experiments, than that it is not advisable to attempt an extreme rate of speed, and that 35 miles an hour, with the existing engine powers, may be considered as the limit of practical speed for passenger trains; combining economy with regularity of transit, and giving due weight to the necessity of accommodating the public, as regards celerity of travelling, to the utmost practicable extent.

If such a conclusion is warranted by these investigations and experiments, then it results that it is not necessary for the attainment of such a rate of speed, that the gauge should be seven feet.

The next proposition is the mechanical advantage of increasing the diameter of the wheels, without raising the bodies of the carriages. We see that there is a diminution of friction by the increase of the diameter of the wheels, but it is doubtful to what extent this is modified by elevating the bodies of the carriages; a broad gauge by allowing the bodies of the carriages to be placed within the wheels, and thus to reduce the height of the carriages, and consequently diminish the area of frontage, is an advantage, considering the great amount of resistance arising from the atmosphere. Then to carry out the premises fully in this respect, we must not give any greater width of frontage than is absolutely necessary for that purpose; it will depend upon the result of further inquiries, as to what superficies in terms of length and width of train affords the requisite accommodation, and presents the least resistance to the atmosphere, which has not been yet determined.

The next proposition, that the increased width of gauge admits all sorts of carriages, stage coaches, &c., to be carried within the wheels, is readily answered; any width of gauge which reduces the height of these carriages above the rails, will be preferable to that width which does not admit of such an arrangement; and the ordinary width, not admitting them within the wheels, renders an increased width, in this respect, advisable, this can, however, be effected with a less width than seven feet.

Increased facilities for the adoption of larger and more powerful engines, for the attainment of a higher rate of speed, has been answered previously; it not appearing necessary for such a purpose that the width should be seven feet. The remaining proposition is, that a wider gauge affords increased stability to the carriages, and, consequently, increased steadiness of motion. The diagrams given will shew how far this has been effected on the present portion of the Great Western Railway, and certainly these documents would prove that this has not yet been accomplished. Considering, however, the causes of the different motions of railway carriages, there can be no doubt, that an increased width of gauge must tend to produce that effect. In the present instance this has been counteracted by the construction and present condition of the road and carriages; and therefore it appears to me the only conclusion we can come to is, that in similarly constructed railways the wider gauge will afford greater stability and steadiness of motion to the carriages.

The objections alleged against the increased width, as detailed in page 8 of this report, no doubt exist to a certain extent: the expense of forming the road track of the railway is increased. This Mr. Brunel estimates at 151,840*l.* for the entire line. The carriages are larger and heavier, and so far, therefore, as the weight acting upon the rails may be objectionable, must be admitted; but I find that Mr. Brunel's statement of the relative weight, per passenger, given in his report at the last meeting of the shareholders (vide Journal No. 12, page 324, vol. 1), confirmed by my enquiries, which shows that there does not exist a greater weight, per passenger, with the Great Western than with other carriages.

The increase of friction in passing the curves does not apply with much weight in your case, the radius of these being so great. The comparative expense of construction of the engines and carriages are not matters of great moment, as there would not be any material difference if the engines were similarly constructed; and the amount, per passenger, is nearly the same with the carriages. The next objection, that it prevents a junction with other lines, does not apply with such force to the Great Western Railway, as it would to some other lines; that railway being complete of itself between the two sides of the island. How far this may be affected by the branches, I am not capable of judging, it being more a commercial than an engineering question; and an opinion could only be satisfactorily given, by an intimate acquaintance with all the circumstances attending the required communication with the adjacent country.

The last objection, that there are no advantages gained commensurate with the increased expense and inconvenience of such a departure, and connection from railways of the ordinary width, does appear from a full consideration to be substantially confirmed; at the same time I must be allowed to say, that there are counteracting advantages, incidental to an increased width of gauge, above that of 56 inches, which should not be overlooked.

Almost all the results arising from these enquiries go to establish a conclusion, that 7 feet is beyond that width which may be considered the best; but these investigations are far from conclusive, in the present state of our information, as to what other width is, under all circumstances, the most advisable to be adopted. Under these circumstances, and considering the great sacrifice of property which would result by the removal of the present rails, and the substitution of any other width; it appears to me that such a step would not be justified by the result of these enquiries. We have only determined one part of the proposition, viz., that seven feet is too great a width; we have not determined the most important section, to what injurious extent it will operate practically. The only results bearing upon this is the increased power required by the enlarged width, and that is in some respects shewn by the increased consumption of coke; which, as per table V., appears to be with the North Star, 21½lbs. per mile, and with the Æolus, 8¼lbs. per mile additional, the former, however, effecting an increased rate of speed of two miles an hour. It is also necessary to state, that the results elicited in the course of this enquiry shew, that considerable modifications may be beneficially made in both engines and carriages; and, therefore, until we have determined, in the most satisfactory and conclusive manner, the precise extent of injury arising from the retention of the present width of gauge, and what width best effects all the objects required, and which, under all the circumstances, is most conducive to the interests of the company, and affords the greatest accommodation to the public, it appears to me the present width should be retained.

Construction of the Road.—The question of the construction of the road comes next under consideration, and here, I presume, there will be less difficulty than in determining on the width of gauge. No doubt can exist, after these experiments, that the piles do not contribute to the firmness of base of the railway, their action seems to prevent the contact of the timbers with the ground; and it is unquestionably proved, that the passage of the engines and carriages along the rails, contributes, with a more powerful effect, to consolidate the road, and produce a greater firmness of bearing to the rails, than the packing connected with the piles.

The principle of having at the end of every 15 feet, viz. at the transoms, a comparatively unyielding bearing, with a scantling of timber intervening very far short of the requisite strength to support the weight of the engines and trains, renders it extremely difficult, if not impossible, to produce a uniform rigidity of surface throughout; and this uniformity cannot be effected by any system of packing, dependent upon manual labour. If continuous bearings are preferable to isolated supports, it appears to me that the most economical, and most perfect plan of construction of continuous timber bearings, is with common transoms; and that a more uniform and firm base will be obtained, by depending on the weight of the trains to ultimately consolidate the base of the timbers, than upon any system of piling, presuming always, that a proper and firm base is prepared in the first instance.

The next consideration is, whether continuous timbers or isolated bearings are preferable; the experiments on deflection show that there is a greater amount of deflection on the continuous timber bearings on both the Great Western and the Manchester and Bolton Railways, than on stone blocks on the other railways; the latter will consequently afford the least resistance to the carriages; and the weight of the stone blocks intercepting to a considerable extent the impact of the trains, they afford a permanently firmer base. We have seen, however, that in high rates of speed, the resistance of the road itself is small, compared with the aggregate resistance; and, therefore, if continuous timber bearings are preferable in other respects, a little additional friction cannot be of very great importance.

There is no doubt that timber bearings produce less noise in the carriages: and it has been urged with considerable force, that the wear and tear of the engines and carriages are less than with stone blocks. I have endeavoured to ascertain this, which is a very important consideration; but the returns of the expenses of the different railways do not, in my opinion, produce conclusive evidence on this part of the subject. The impression produced in my mind by the information obtained, however, is, that with longitudinal timber bearings of adequate rigidity and strength, the injury to the engine and carriages will be less than with stone blocks. The case of the Dublin and Kingstown Railway has been often quoted, as exhibiting an instance of the great destruction to the engine and carriages, and road itself, by the use of stone blocks; and the cross wooden sleepers in Chat Moss, and the American railways, as instances of the utility and cheapness of keeping in repair, the timber bearings. Every engineer, however, knows that the Dublin and Kingstown rails were much too weak for the stone blocks on which they were placed; and the inferior rate of speed on the American railways affords no criterion whereby to compare with the effect of stone blocks in this country, where a much higher rate of speed is practised,—the peculiarity of base of Chat Moss likewise, does not admit of any comparison with stone blocks on a firm foundation. Notwithstanding this I am inclined to think, that the wear and tear of the carriages and engine upon timber bearings of a proper strength will be less than upon stone blocks;—of the comparative durability no definite comparison can yet be made.

These experiments, however, show that the present scantling of timber on both the Great Western and the Manchester and Bolton Railways, are much too small for the loads which come upon them; and that they do not present a sufficiently rigid and unyielding base for a railway. One set of experiments (No. 7, Part I. Book A.), on the Great Western Railway, on the continuous timbers without piles gave very satisfactory results, but here the scantling of the timber was 10 inches; it appears to me, therefore, that if continuous timber bearings are used, they should be of a scantling of timber greater than that at present in use; and it appears, also, that a more rigid section, and greater weight of rail should be adopted.

This will, no doubt, make the continuous timber bearings more expensive than stone blocks, against which we have less noise, and a smoother, and a more perfect road for high rates of speed; sufficiently strong continuous timbers present, in fact, a more perfect, but a more expensive line of road than stone blocks;—of the comparative durability no satisfactory conclusion can be drawn. At a lower rate of speed, and where economy is an object, stone blocks being cheaper, will be preferable.

I have not in this comparison noticed cross timber sleepers, as compared with continuous timber bearings; as temporary roads, during the consolidation of embankments, the cross sleepers will be preferable; but the result of the experiments on deflection show, that there is not only a very considerable yielding of the timbers, but that there is likewise an imperfect fastening between the chairs and sleepers, which cannot be remedied without increased expense and difficulty; this road is much cheaper than either adequately strong continuous timbers, or stone blocks, but it is less perfect, and cannot be considered as a permanent description of road.

With respect to that part of your request, which relates to the examination of the Maidenhead Bridge; while on the works in September last I minutely examined the state of the arches and the plan of construction;—the cause of its failure appeared to me to have been occasioned by the centering being prematurely drawn, and before the cement was perfectly hardened and had taken a set in the interior of the brickwork forming the ring of the arch. Mr. Brunel at that time pointed out to me the remedies which he proposed to repair the d-fects, in which I concurred, and those I understand have not yet been completed.

In conclusion, I trust that the magnitude and variety of the objects, and the great and imposing interests embraced in this inquiry, added to the great responsibility attached to the investigation, will be a sufficient excuse for the protracted time occupied in making the experiments; and I trust, also, that these reasons, together with the unexpected and important results which have arisen out of these inquiries, will be deemed by you and the shareholders at large, to be a sufficient apology for the delay which you have experienced in not receiving this report at the time originally contemplated; to comply with which, to the utmost extent in my power, must also be my apology for the imperfect manner in which this document is presented to your notice.

I am, Gentlemen,

Your most obedient servant,

NICHOLAS WOOD.

REPORT OF I. K. BRUNEL, ESQ.

TO THE DIRECTORS OF THE GREAT WESTERN RAILWAY COMPANY.

Gentlemen,—I have now before me the report of Mr. Wood, the latter part of which I received only on the 17th. The appendix, without which, for all purposes of investigation, the report is incomplete, I have not yet received.

Considering the great mass of valuable matter contained in this report in the shape of numerous experiments, of calculations founded upon them, and the discussion and examination of the results and their consequences, the collection and consideration of which have occupied several persons for about three months, it will not surprise you that I should find a few days a very short period in which to make myself sufficiently master of its contents to be able to lay before you my observations thereon.

The extremely short time which circumstances allow me will prevent my entering into a detailed examination of the various tables of experiments which appear in the body of the report, or, in fact, doing more than refer to the principal points and those general results which appear to have mainly influenced Mr. Wood's opinions. Fortunately, the clear and methodical manner in which these various results are arranged, and the fair and impartial way in which they are treated, will render this an easy and comparatively an agreeable task, and will enable me to select such points as I consider most important, and to separate such facts and conclusions as relate to these particular points.

The satisfaction which I feel in approaching a subject, when treated in this manner, is, however, very much diminished by one source of great regret; and if in the course of the following observations I should have occasion to differ from Mr. Wood, either in the view he takes of the reliance to be placed on, or the consequences resulting from, any particular experiment, I ascribe this difference of opinion almost entirely to the cause which I shall refer to.

I think it is deeply to be regretted that Mr. Wood should not have been able himself to have attended to and conducted all the experiments. I do not mean to imply the slightest doubt of the accuracy of the records of the facts as they were observed; but that constitutes but a small part of the duty of collecting evidence upon doubtful points, particularly when they relate to questions of mechanics and science, which may be affected by a great variety of causes, and where the results may be influenced and entirely changed by the manner in which they are obtained.

It is certainly my opinion, that had Mr. Wood personally superintended the experiments; had he brought his own practical knowledge of the subject to bear upon them; he would have discovered many operating and interfering causes, which either would have led him to repeat his experiments by other methods, or to explain apparent anomalies, and thus, in my opinion, upon many of the most important points to come to very different conclusions. But more especially do I think his opinions would have been changed upon all those points which are necessarily capable of alteration and amendment by the knowledge and experience daily gained in the working of a system new in many of its details; and that before he drew definite conclusions, founded, inevitably, upon very imperfect data, he would have made a larger allowance for that progressive improvement which practice, observation, and experience, never fail to produce.

To no part of the system do these remarks apply more strongly than to that of the performance of the locomotive engines, and the question of the practicability of attaining high speeds; and as almost the only conclusions arrived at in the report upon which I think it necessary to epxress any material difference of opinion, are founded entirely upon the results of experiments made to determine these points, I shall apply myself principally to the consideration of them, and the experiments by which they were obtained.

In order to show that I am not attaching undue importance to any one part of the report, or to any one section of the experiments, I shall refer briefly o the general arrangement of the report, and to the order in which the conclusions are arrived at.

After stating the general questions to be treated, and the advantages and objections which have been urged for and against the plans which have been adopted on this railway, Mr. Wood arranges under three principal heads the points to be determined by experiments, viz.:—

"1st. The question of the attainment of a higher rate of speed than on other railways; whether the increased width of gauge is, or is not, either necessary or best adapted for the accomplishment of this object, and to what extent.

"2nd. The mechanical advantage or diminution of friction, by being enabled to increase the diameter of the wheels without raising the bodies of the carriages; and in what respect, and to what extent, the friction or resistance of the carriages is affected by, or bears upon, the peculiar construction of the road.

"3rd. The comparative advantage or firmness of base, or road track, of the Great Western Railway, with continuous timber bearings, either with or without piles, and if it does or does not produce a greater steadiness and smoothness of motion to the carriages, and to what extent.

"These were the questions," the report continues, "which it appeared to me could not be determined in any other way than by experiment, but which appeared to be capable of solution by that method, and which likewise appeared to constitute the foundation of the entire system."

The first division consists of summaries of experiments, the details of which are to be given in an appendix, and of observations upon the performance of the Great Western engines, as compared with those of other railways, and the comparative performance of all at different velocities. These constitute the first section, and occupy the report to page 63. From thence to page 65 of the report is devoted principally to some experiments made upon the resistance of the air to the moving train, with a view to account for, and to ascertain the causes of, the results apparently obtained in the experiments recorded in the preceding section. The third section, from pages 65 to 68, is devoted to the investigation of the stability of the rails and carriages. The remainder of the report is occupied with the conclusions arrived at, founded upon the preceding observations and results.

As regards the construction of the road, to which the third section principally relates, Mr. Wood appears to be of opinion, that for high speeds, continuous longitudinal bearings of timber form a good road, and that the mode adopted on the Great Western Railway of securing the rail to the timber is good; but that the system of piling is bad, and that the weight of rail and scantling of timber hitherto adopted on the portion of the line completed, are insufficient. All this is in perfect accordance with the plans proposed for the future construction of the road. A rail considerably stiffer and longitudinal timber of greater scantling are prepared, and a plan has been recommended to you and approved of, in which the use of the piles is abandoned. Though I do not, therefore, differ from Mr. Wood in his results, I think it right to say here, as regards the experiments themselves which are recorded, that those upon the deflection of the rails of the Great Western Railway necessarily give a much less favourable result than would have been obtained had an average been taken of experiments over the whole line: these experiments have been confined almost exclusively to a short space of about two miles in the clay cuttings in the neighbourhood of Paddington, where we have always met with the greatest difficulties, and which is undoubtedly the worst part of the road. I conclude that this was accidental, and that want of time alone has prevented further experiments being made; nevertheless, the results must not be taken as a correct average of the line. As regards those upon the comparative smoothness of the carriages, I am bound to say that I doubt the accuracy of the instruments. I always maintained that they were not correct in principle, and were quite capable of indicating greater movements in an easy carriage or on a good road, than in a rough carriage or on a bad road, if the motion of the former should happen to coincide with the natural motion of the instrument; or, if the former should be of a character to which the instrument, from its construction, might be more susceptible. If the instrument were good as a comparative measure, it would, of course, in each experiment, indicate the rough and smooth portions of our line. Now certainly, according to the Table 15, there are no indications which would enable us to point out correctly these different parts of our line, although they are distinctly perceptible to the traveller, and well known to us. And, upon turning to the Table, and the corresponding portions of the line referred to, I find, from an exact knowledge of every part of it, that the numbers indicate rather the reverse of the fact, giving the lowest amount between the second and seventh miles, which is a bad part, and the highest between the seventh and fifteenth, where the road is good. It is not, however, upon this discordance in the results that I found my objection to the instruments used. They might have been correct, whilst the instrument was faulty. But considering the principles upon which they were constructed to be unsound, and as I do not hence attach much importance to the results, I only now allude to them, to prevent my silence being misunderstood.

But, in the absence of an accurate instrument, the public are perhaps most competent to determine whether, on the whole, they find the travelling on the Great Western Railway as comfortable, and the motion as easy, even at present, as upon other lines; and this, notwithstanding the shorter time our road has been opened, the greater speed of our engines, and that as yet we work under all the disadvantages of new tools (carriages and road inclusive), in which experience is absolutely necessary to adapt the various parts to each other. Unless, indeed, instruments are contrived which shall separate the different sources of motion, and measure them accurately, they will hardly afford as correct information as the mere sensations of a careful observer.

Upon the question of the assumed amount of resistance from the air, as deduced from experiments made upon that part of the Liverpool and Manchester Railway called Whiston inclined plane, if, practically, the high speed be attainable, as I will prove it to be without the extravagant consumption of fuel which was supposed to be unavoidable, it is perhaps unnecessary to occupy your time at present with an inquiry into the subject. But as it has been looked upon as the discovery of a new cause brought into operation, from which we are to apprehend new and hitherto unexpected results, I must say a few words upon it. The resistance to a body moving through the air has long been known, and although perhaps not with perfect accuracy, yet tables giving a near approximation were made and published sixty or seventy years ago, by Smeaton, (Phil. Trans. 51st vol.,) as well as by other eminent men, and are now to be found in most elementary works.

Any calculations founded upon these Tables shew that resistance of the atmosphere is very considerable, and varies in some ratio approaching to that of the squares of the velocities. I have long since, and frequently, made such calculations, which I believe, if judiciously made, would give more correct results, though not nearly so large as the experiments before us; they would at least be free from several very serious sources of error.

That there must have been some great sources of error is evident from the striking discrepancies between the result of the experiment on the Whiston plane and every day's experience upon it. The passenger train, in descending this plane, with the steam shut off the engine, which then causes some considerable resistance, frequently acquires a very high velocity, exceeding forty miles rather than thirty miles per hour, and requiring the use of the break. This I have seen occur without any favouring wind, while in the experiments, notwithstanding the assistance of a breeze, the carriages did not acquire a velocity of more than 32½ miles per hour. Although this is so contradictory, there is nothing really inconsistent with the full operation of resistance of the atmosphere, but merely an evident indication of the circumstances being quite dissimilar in the experiment from those which occur in actual practice.

Again; in the experiments themselves, a circumstance is mentioned which destroys the apparent agreement between the result and the theory, and which would prove that the resistance of the atmosphere is even much greater than is stated, and in fact makes it so excessive, and so different from the result obtained from the experiment on the Madeley inclined plane, which is also given, as to destroy any dependence upon either of them.

It is stated in p. 65, that "there was a pretty strong wind directly in favour of the motion of the train, down the Whiston plane." Now, 10 miles an hour is below the velocity of anything that can be called "a pretty strong wind," —but assume 10 miles, so as to be on the safe side—deducting this from the 32½ miles, we have 22½ as the real velocity of the train passing through the air, or the velocity to which alone any atmospheric resistance could be due. At this velocity, 2,3lbs. per square foot would be the utmost effect that could be produced by the air, and the 329lbs. ascribed to atmospheric resistance would therefore require 143 square feet of surface: if the four carriages had been placed by the side of each other instead of behind, this surface would hardly have been obtained; or, again, if the 329lbs. were due to the atmospheric resistance of four carriages of the narrow gauge at 22½ miles per hour, at 40 miles the same four carriages would meet the resistance of 1,063lbs., which alone, without any allowance for friction, or for the increased width of carriages, would be a greater resistance than the North Star engine is capable of overcoming. But the North Star, as I shall hereafter shew, does take a train of seven carriages, weighing 46 tons, and having seats for 188 passengers, at 40 miles per hour, which according to the above data would require, including friction, a tractive power of somewhere about 1,500lbs., probably nearly double that which the engine can possibly exert at that speed. But these discrepancies are easily accounted for.

The experiments were made with very light loads, 15½ and 18 tons; and consequently the assumed comparative resistance for the air, which would be nearly the same even had there been 50 tons, appears much larger. The friction of 50 tons would have been 285lbs., and the atmospheric resistance being still 329lbs., the relative per centage of the total resistance would have been 44 and 56, and to the 44 per cent. has to be added, all the friction of the engine itself, which is also a constant quantity independent of any resistance of the air; taking this at 15, or one-third of that of the trains, the proportion becomes 51 for friction, and 49 for some other resistance, instead of 22 and 78.

But the sources of error to which I have alluded are much more serious, and appear to me so incapable of measurement, and consequently of correction, as to render the experiments useless.

The circumstances were not really, though apparently so, in any one point similar to those of an ordinary train in motion. In the first place, the carriages are sent with the square end to meet and receive the full resistance due to their surface, which is totally different from the case when the engine precedes them. In the next place, this resistance is acting entirely against the front of the first carriage of the train, while the motive power,—viz. the gravity, is behind, that is, acting upon each carriage, and pushing one upon another. Everybody experienced in railways knows that in such a case the carriages are thrown out of square, and a degree of resistance created which would alone account for the whole.

The ultimate conclusions, however, at which Mr. Wood arrives on all the principal points, will, upon perusal, be found to have been governed by the results of the experiments upon the performance of the engines, and the assumed resistance of the trains at high speed; the experiments upon the resistance of the air being made to ascertain if this assumed increase of resistance could be accounted for.

The mechanical advantage of large wheels for the carriages is, of course, admitted; but high speeds being assumed to be practically or economically unattainable, the reduction of friction is considered unimportant. I shall now, therefore, consider this branch of the subject—the performance of the engines.

The locomotive engines running upon the ordinary railways are the result of nearly ten years' experience; during which time the most talented manufacturers have been constantly engaged, not in inventing any new construction of engine,—for certainly, seven, if not eight years since, Messrs. Stephenson constructed, what, in form and general arrangement, was exactly similar to that now made,—but simply in adapting and proportioning the different parts the one to the other, and by such trifling changes, if they can be called so, important improvements have been effected, and greater speed and economy attained.

On the engines made for the Great Western Railway the same experienced manufacturers have been employed; but as a higher speed was sought, a larger evaporating surface of boiler was required; and many of those proportions which had been long studied, and in which perfection had to a great extent been attained, were necessarily altered: and yet these machines, brought into operation without the possibility of any sufficient previous trials, in which their defects could be discovered or improvements introduced, are taken as the full measure of what can be effected in the new system of which they form a part. It is certainly contrary to all experience to suppose that they should at once be well adapted to a new system; for not only would this have required more foresight than the most eminent of those engaged in their construction could possibly possess, but it involved a departure from many rules in favour of which long and successful experience had, to a certain degree, created a prejudice.

The experience of at least some months of the actual working of these engines, and that at a time when we should be sufficiently free from all the embarrassments of the first opening of the line to allow of such alterations being tried as appeared likely to effect improvements, which involves the ability to throw out of work any engine upon which it might be necessary to make the trial; some such short experience and such trials were at least necessary to bring the system even on a par with others long previously in operation; but this opportunity we have not yet had.

From the results obtained up to the present time, therefore, little could be hoped for beyond very clear and decided indications of all defects, while the advantages were still to be acquired; and if, under such circumstances, the performance had been nearly equal to that obtained on other lines, with the benefit of long experience, I should have been satisfied We should have had a right to expect great improvements; we should have started from the point at which others had arrived; and when we had attained the same relative perfection in all parts which they had, with all the advantage of their previous experience, and which we might calculate upon doing in a much shorter time, we should be as much in advance of our present state as they are now of the state in which they were some years ago.

But I am prepared to shew that we are now in that position; that the performance of our engines is not merely as great, but greater, than that which has yet been attained on other lines; that those changes and improvements to which I have alluded are just commenced; and that, even since Mr. Wood made his experiments, the advance has been so great, that if he were now to repeat them he must arrive at totally different conclusions.

Tables III. and IX. of his report give the performance of engines with different loads on the London and Birmingham, and on the Great Western Railway. From them it would appear, that on the Birmingham Railway the same engines which took 60 and 64 tons at 24 and 25½ miles per hour, were only capable of taking 34½ and 33 tons at 32½ and 33 miles per hour, with nearly double the consumption of coke per ton; while on the Great Western Railway the same engine—the North Star, was capable of carrying 82 tons at 33 miles per hour; only 33 tons at 37 miles per hour, and 16 tons at 41 miles, and to obtain which last additional velocity of four miles per hour the consumption of coke per ton was more than doubled.

Such an enormous diminution of effect by a comparatively small increase of speed, if unavoidable, or necessarily consequent on the increased resistance of the train, would undoubtedly justify the conclusion arrived at by Mr. Wood, that to attempt to exceed 35 miles per hour is not advisable; and consequently, that so far as the system of the Great Western Railway was adapted for high velocities it was unsuccessful. But these conclusions are founded upon the statements above referred to. Experiments have since been made giving very different results, and I can prove, that if an engine be properly constructed for high speeds in the manner which I have always proposed, that there is no such "immense sacrifice of power incidental to an extreme high rate of speed, or the accomplishment of a rate of thirty-eight or forty miles per hour above that of thirty-two or thirty-five miles," (page 63;) and that the same engine, which was then only capable of taking sixteen tons at an average velocity of thirty-eight and a maximum of forty one miles and a half per hour, is now capable of taking forty tons at an average velocity of forty miles per hour; and further, that the consumption of coke per ton, so far from being extravagant, is not so great as that of the engines on the London and Birmingham Railway, when only travelling at a mean rate of thirty miles per hour.

The experiments have been made with the same engine and the same class carriages as those used in Mr. Wood's experiments, and in every other respect conducted in the same manner, and without any attempt to diminish the resistance of the air, which may be done to a great extent, and which as I shall hereafter have occasion to state, was always my intention, and has been prepared for in the construction of engines and carriages.

The comparison between the performance of this engine in September last and at the present time will therefore stand thus:—

	Load. Tons.	Average speed.	Consumption of Coke per ton per mile.
September,	15.9	38½	2.76
December,	40	40	.90

From which it appears that in less than three months (the change has really been effected but lately) the performance of the engine is nearly trebled, while the consumption is reduced to a moderate quantity, or by two-thirds of that of the former experiments.

The explanation of this change is easily given. The great diminution in the useful effect of the engine in the former experiments did not arise solely from the increased resistance of the train—which might have been more difficult to overcome—but principally from the diminished power of the engine at that speed. This might appear, at first sight, to be the same thing, but such is by no means the case. The increased resistance of the load to be moved might arise from causes which could not be controlled. The diminished power of the engine might be a mechanical defect, capable of being remedied, and investigation has proved the truth of this most satisfactorily. The engines at that time were so regulated by the proportion of some of their parts, that their power was crippled when the speed was increased. The great quantity of steam which is required, could not, in fact, escape, and if allowed to escape more freely, there was a deficiency of draft in the furnace. This was a difficulty incidental to the high speeds, and also to the increased diameter of the driving wheels, but it is a difficulty which is capable of being overcome, and, in a great measure, has been overcome. There is, however, no doubt, still room for improvement; but if, in so short a time, we have made this great advance, it is fair to presume that we may make still further improvements.

If, therefore, great speed is attainable—if there are no natural causes, no insurmountable obstacles—the position taken by Mr. Wood (and in taking which he was perfectly justified, by the evidence before him) becomes totally changed. The hypothesis is no longer correct on which the opinion was formed and expressed in page 68, in the following words:—"If such a conclusion"—viz., the practical limit of 35 miles per hour—"is warranted by these investigations and experiments, then it results that it is not necessary for the attainment of such a rate of speed that the gauge should be seven feet." But all the advantages pointed out in the two following paragraphs of the Report as resulting from an increased width of gauge over the four feet eight inch, apply in a still greater degree than under the circumstances which existed at the time. Some doubts are expressed as to the advantage of so great an increase of gauge as seven feet; but these doubts, again, appear to arise entirely from the circumstance, that the results of the experiments then made upon the performance of the engines were unfavourable. The reverse appears now to be the case; the work performed with a given consumption of coke is much greater than in any of the experiments made upon other lines, the details of which are given in the Report.

On the subject of the seven-feet gauge, I can add very little to what I have said before. It was adopted expressly to enable us to effect that arrangement which is recommended at page 68.

"We see that there is a diminution of friction, by the increase of the diameter of the wheels, but it is doubtful to what extent this is modified by elevating the bodies of the carriages; a broad gauge, by allowing the bodies of the carriages to be placed within the wheels, and thus to reduce the height of the carriages, and consequently diminish the area of the frontage, is an advantage, considering the great amount of resistance arising from the atmosphere."

To effect this, with the most convenient form of body, similar to that ordinarily adopted on railways, does require, as I have frequently stated in previous reports, a width of at least 6 feet 10 inches.

The advantage of stability is probably directly in proportion to the increased width; and upon this point I will quote the words of Mr. Wood, page 68:—

"The remaining proposition is, that a wider gauge affords increased stability to the carriages, and, consequently, increased steadiness of motion. The diagrams given will show how far this has been effected on the present portion of the Great Western Railway, and certainly these documents would prove that this has not yet been accomplished. Considering, however, the causes of the different motions of railway carriages, there can be no doubt that an increased width of gauge must tend to produce that effect. In the present instance this has been counteracted by the construction and present condition of the road and carriages; and therefore, it appears to me, the only conclusion we can come to is, that in similarly constructed railways the wider gauge will afford greater stability and steadiness of motion to the carriages."

As regards the expense of forming the railway of increased width, Mr. Wood has made a mistake, which I believe he will correct in the Appendix. The estimate of the increased cost is £39,000 only, instead of £151,840. Upon all these points I have so frequently explained my views to you, that I shall take the liberty to quote a passage from my report of the 15th of August, which contains in a small compass the grounds upon which I adhere to my opinions in favour of the width of gauge I have selected:—

"It has been asserted that four feet eight inches, the width adopted on the Liverpool and Manchester railway, is exactly the proper width for all railways, and that to adopt any other dimension is to deviate from a positive rule which experience has proved correct; but such an assertion can be maintained by no reasoning. Admitting, for the sake of argument, that, under the particular circumstances in which it has been tried, four feet eight inches has been proved the best possible dimension, the question would still remain—What are the best dimensions under the circumstances?

"Although a breadth of four feet eight inches has been found to create a certain resistance on curves of a certain radius, a greater breadth would produce only the same resistance on curves of greater radius.

"If carriages, and engines, and more particularly, if wheels and axles of a certain weight, have not been found inconvenient upon one railway, greater weights may be employed, and the same results obtained, on a railway with better gradients.

"To adopt a gauge of the same number of inches on the Great Western Railway as on the Grand Junction Railway, would, in fact, amount practically to the use of a different gauge in similar railways. The gauge which is well adapted to the one is not well adapted to the other, unless, indeed, some mysterious cause exists, which has never yet been explained, for the empirical law which would fix the gauge under all circumstances.

"Fortunately, this no longer requires to be argued, as too many authorities may now be quoted in support of a very considerable deviation from this prescribed width, and in every case the change has been an increase.

"I take it for granted that, in determining the dimensions in each case, due regard has been had to the curves and gradients of the line, which ought to form a most essential, if not the principal, condition. In the report of the commissioners upon Irish railways, the arguments are identically the same with those which I used when first addressing you on the subject in my report of October, 1835.

"The mechanical advantage to be gained by increasing the diameter of the carriage wheels is pointed out; the necessity, to attain this, of increasing the width of way; the dimensions of the bridges, tunnels, and other principal works, not being materially affected by this, but, on the other hand, the circumstances which limit this increase being the curves on the line, and the increased proportional resistance on inclinations (and on this account it is stated to be almost solely applicable to very level lines), and lastly, the increased expense, which could be justified only by a great traffic.

"The whole is clearly argued in a general point of view, and then applied to the particular case, and the result of this application is the recommendation of of the adoption of 6 feet 2 inches on the Irish railways. Thus an increase in the breadth of way to attain one particular object—viz., the capability of increasing the diameter of the carriage-wheels, without raising the bodies of the carriages, is admitted to be the most desirable, but is limited by certain circumstances,—namely, the gradients and curves of the line, and the extent of traffic.

"Every argument here adduced, and every calculation made, would tend to the adoption of about 7 feet on the Great Western Railway.

"The gradients on the lines laid down by the Irish commission are considerably steeper than those of the London and Birmingham Railway, and four and five times the inclination of those on the Great Western Railway; the curves are by no means of very large radius, and, indeed, the commissioners, after fixing the gauge of 6 feet 2 inches, express their opinion that, upon examination into the question of curves, with the view to economy, they do not find that the effect is so injurious as might have been anticipated, and imply, therefore, that curves, generally considered, of small radius on our English lines, are not incompatible with the 6 feet 2 inch gauge; and lastly, the traffic instead of being unusually large, so as to justify any expense beyond that absolutely required, is such as to render assistance from government necessary to ensure a return for the capital embarked. As compared with this, what are the circumstances in our case? The object to be attained is, the placing an ordinary coach body, which is upwards of 6 feet 6 inches in width, between the wheels; this necessarily involves a gauge of rail of about 6 feet 10 inches and a half to 6 feet 11 inches, but 7 feet allows of its being done easily; it allows, moreover, of a different arrangement of the body; it admits all sorts of carriages, stage-coaches, and carts, to be carried between the wheels. And what are the limits in the case of the Great Western Railway, as compared to those on Irish railways? Gradients of one-fifth the inclination, very favourable curves, and probably the largest traffic in England.

"I think it unnecessary to say another word to show that the Irish commissioners would have arrived at seven feet on the Great Western Railway by exactly the same train of argument that led them to adopt 6 feet 2 inches in the case then before them.

"All these arguments were advanced by me in my first report to you, and the subject was well considered."*

All the opinions expressed, and the arguments advanced by me on that occasion, I consider to be supported by the general arguments of Mr. Wood, and fully borne out by the experiments recorded in his report, when taken in conjunction with those recently made.

The experiments made during the progress of Mr. Wood's investigation, and those, few in number, which I have been enabled to make since, have given much useful information upon many points connected with the working of the line; and, while they confirm the views which I had previously taken, they also point out many imperfections which are capable of removal. Upon the value of gradients particularly, the records of the experiments made for Mr. Wood, give most conclusive evidence. Upon an average of about eighty experiments made with several different engines, and various loads upon our line (with the manuscript details of which Mr. Wood has kindly furnished me), the mean velocity, after the speed was acquired in ascending a plane of eight miles in length of four feet per mile, was 30¾ miles; on a short level summit of only half a mile, the speed increases to 32¼; and the average of the next seven miles, on which the levels vary from 4 feet to 2 feet per mile descending, the velocity was 34¼; and upon the remainder of the line, which varies from 2 feet to 4 feet per mile ascending, the velocity is 33¼. The velocity upon the latter part is rather greater, from the circumstance of its being near the conclusion of the journey, the engineer being thereby enabled to reduce the feed or the supply of cold water to the boiler, or to avoid adding fresh fuel and in other ways to maintain the steam.

This result gives a clear difference of four miles per hour between the velocities in ascending a plane of eight miles in length, at four feet per mile, and descending a plane of seven miles in length, averaging about two feet six inches per mile. Nothing can be more conclusive as to the actual practical effect of even any very slight increase or diminution of the gradient of a line, notwithstanding the vaguely expressed assertions—not that I mean to imply that such are found in Mr. Wood's report—that after a certain degree of perfection is attained it is useless to seek a nearer approach to a level.

The observations which I have lately made upon carriages moving with a high velocity satisfy me that a very great portion of the resistance at such velocity is caused by the rolling of the carriage wheels from side to side. And in proportion as this source of resistance is removed, which it undoubtedly may be in a great measure, if not entirely, so will the useful effect of the engine be greatly increased.

I should have been glad to have taken this opportunity of entering more fully into the various questions, the agitation of which has led to these experimental inquiries. But in order to comply with your desire to have my observations printed and circulated this week amongst the proprietors, I am compelled, though most unwillingly, to bring them to a conclusion.

It is but justice to myself to add, that being thus limited in time, I am deprived of the opportunity of which I should, under other circumstances, have readily availed myself, to examine most minutely every experiment and inference drawn in the report, as well as of fully explaining, and I hope I may add, of vindicating, the views and principles which, with your sanction and approval, I have hitherto acted upon in the construction of the Great Western Railway.

I am, gentlemen, your obedient servant,

(Signed) I. K. BRUNEL.

London, December 27th, 1838.

At the special meeting of the shareholders, held on the 9th of January, the report of the directors was approved and adopted.

PROCEEDINGS OF SCIENTIFIC SOCIETIES.

INSTITUTE OF CIVIL ENGINEERS.

[It affords us much pleasure to publish the following very interesting annual report of the Institute, and to announce the removal of the Institute to premises in every way suitable to the station and rank in which the profession is justly held by the public. The house which has been lately fitted up for the members is one of the splendid mansions in Great George Street, Westminster. In the rear there is a very convenient theatre, capable of holding at the least 150 members, where the proceedings and discussions of the Institute will be conducted.]

Annual Report, 1839.

It is with feelings of the greatest satisfaction, that the council invite the attention of this meeting to the following report, the presentation of which terminates the trust confided to them by the last annual general meeing.

The twentieth year of the proceedings of the institution has been marked by events of considerable importance, furnishing the strongest evidence of the steady progress and success which has attended the labours of the council, aided as it has been by the unanimous co-operation of the general body. To meet on the present occasion, under circumstances more favourable than perhaps attend any similar society is most gratifying; but the gratification stops not here, to form a proper estimate of your present condition, it is necessary to contrast that of earlier years with the steadily increasing progress of the last. In fulfilling the more extensive duties consequent on this progress, as well as on the many important changes which have taken place, the council have always been deeply sensible of the high responsibility committed to them, and that their endeavours have been well directed, will they trust be apparent from the present report, to the details of which they now solicit your careful attention.

New Premises.—The hopes which were at the last annual meeting held out respecting the present premises have been more than fully realised. The kindness of the commissioners of compensation, in resigning at midsummer, that portion of the premises in which the more important alterations were to be made, has enabled the council to commence the session in the present place, and though the repairs be yet incomplete, the council believe they will be completed ere the institution again meets. The alterations and repairs will be executed for about £1,000. More than £700 has been already subscribed, and among the many gratifying circumstances of the past year, the council would particularly select the liberality with which all have come forward to further this object.

Such has been the unanimity of feeling evinced in this respect that the council believe ample resources will be found, and that the future council will not have to avail themselves of the liberal offer of your president to advance whatever sum the institution might require.

The existing furniture is all available for the present premises, and the outlay which will be required for what more may be desirable for your comfort and suitable accommodation will not be greater than the growing resources of the institution can conveniently meet, so that there is no danger of any permanent debt being entailed on the funds of the institution. By the terms of the lease you are secured from the expense of serious repairs, and from the completeness with which on the present contract they will be executed, the council do not anticipate that any thing further of importance will be required for many years to come.

By-laws.—The council would next advert to other subjects which have occupied their attention during the past year, some of which were dwelt upon at length in the last annual report. It will be in the remembrance of most, that during the year preceding the last annual meeting, some changes were made in the constitution of the general body and of the council. The more important of these changes were, the incorporation into the class of members, without distinction of residence, of all those whose professional qualifications were recognized as the same; the creation of a new class under the term graduates, to include those who either as pupils or assistants to engineers, were qualifying themselves for the practice of the profession on their own account; the increase of the number of the council, and the addition of two as representatives of the class of associates. The council, on the experience of the past year, conceive that these and other important changes recommended by their predecessors in office, and adopted by the general meeting of members, have contributed to the success and permanent stability of the institution.

The council conceive that the introduction of two from the class of associates may be attended with great benefits to the institution. This change has been objected to by some zealous friends of the institution among the associates themselves, on the ground that such an introduction might tend to divert the attention of the institution from objects strictly professional. The council, however, do not conceive that such fears have any just foundation, so long as the rest of their body consists of men honoured by the confidence of the profession, but on the contrary, that the class of associates containing many distinguished for their attainments in pursuits intimately connected with the practice of the civil engineer, will furnish those who may co-operate in advancing not only the interests of the institution, but the cause of general knowledge. The council cannot omit to bear testimony to the valuable services of Mr. Carpmael and Lieutenant Denison during the preceding year, and they would repeat the recommendation made to the last annual meeting, that two of the class of associates be elected on the council of the ensuing year.

Other alterations have been suggested, on which the council have bestowed much deliberation, and in case the future council should think it advisable to summon a general meeting of members to consider the propriety of making any alteration in the existing laws, it may be advantageous briefly to advert to one or two of the proposed alterations which have occupied the attention of the council during the past year. It has been suggested that the annual election of the council should be conducted in a somewhat different manner from that at present pursued. That a greater number than that constituting the council should be nominated, and that each person at the annual general meeting instead of, as at present, erasing one name and substituting another, erase as many names as the number on the ballotting list exceeds the constituted number of the council. It has also been suggested whether it may not be for the advantage of the institution, that the council should be increased by the addition of two members; that as frequently some of its most distinguished members are inevitably prevented by professional engagements from attending the ordinary meetings, the council should be enlarged to as great an extent as may be consistent with the true interests of the institution.

Members.—The council have frequently experienced difficulty in deciding on the qualifications for admission into the class of members. It is a peculiar feature in your institution that the class of members should consist of those strictly engaged in the practice of the civil engineer. The objects of the civil engineer are defined by your charter, and the council, considering that the success and permanency of the institution must depend in a great measure on the care exercised in admission into this class, have repeatedly considered this subject with the view of presenting some definite rules for the guidance of themselves and others. It has appeared that they will be aided in this difficult task by adhering as much as possible to the two following conditions; either:—

He shall have been regularly educated as a civil engineer according to the usual routine of pupilage, and have had subsequent employment for at least five years in responsible situations as resident or otherwise in some of the branches defined by the charter as constituting the profession of a civil engineer; or, he shall have practised on his own account in the profession of a civil engineer for five years, and have acquired considerable eminence therein.

It is thought that the first condition will include those who by regular education have done their utmost towards themselves for the profession, and that their subsequent employment in responsible situations will be a guarantee that they have availed themselves of the opportunities which they may have enjoyed.

In the earlier days of the science of the civil engineer such a condition would have been inapplicable; then the force of native genius sufficed to place the individual in that position of professional eminence which commenced with a Brindley and a Smeaton, and was in our own time exemplified in a Rennie and a Telford. To such, of whom there are many illustrious examples amongst us, the second condition is strictly applicable.

Transactions.—Since the close of the last session the second volume of the Transactions has been published. The council regret that the volume should have been delayed so long beyond the expected time, but they would remind the meeting that the preparation of a volume containing 23 highly-executed plates, is a work of no ordinary difficulty, and that a delay in any part will of necessity preclude the publication of the volume. The danger of delay, when a whole volume is to be published at once, has led the council to consider whether it would not be for the interest of the institution to publish in parts of volumes, and from time to time, as they can be prepared, such communications as are destined to occupy a place in the Transactions. The advantages resulting to all parties from such an arrangement would, it is conceived, be great; delay in the publication of a body of communications, by reason of the incompleteness of one of them, would be entirely avoided, authors would surely gladly avail themselves of this method of transmitting papers to the world, since all the merit due to priority of claim would then be undoubtedly secured to them.

Minutes of Proceedings.—Should, however, the succeeding council consider the propriety of adopting some plan similar to the above, for the publication of the Transactions, the council would urge the importance of adhering to the publication of the minutes of proceedings. In these are recorded many communications of partial and transient interest, which would be comparatively of little value unless published at the time. By these the public is at once brought into immediate contact with the institution, the labours of authors can be extensively made known, their merit in the priority of invention and discovery secured as a matter of history, and their opinions canvassed almost as soon as promulgated by many competent judges, who are unable to attend the meetings.

Telford Premiums.—At the close of the preceding session the council issued a list of subjects to adequate communications, on which they would award Telford premiums. The following communications were received:—A most elaborate and beautiful set of drawings of the Shield at the Thames Tunnel, from Mr. Brunel, and two sets of drawings of Huddart's rope machinery, the one from Mr. Birch, the other from Mr. Dempsey. The merits of this celebrated shield, and its value as a means of executing works similar to the Thames Tunnel, are so well known, that it were superfluous here to insist upon the benefits which Mr. Brunel has, by the invention of it, conferred on the civil engineer. The council, feeling that this communication and the invention of the shield were entitled to a high mark of approbation, determined on presenting Mr. Brunel with a silver medal, accompanied by a suitable record of the sense entertained of the benefit conferred by him on the practice of the civil engineer. Feeling also that the beauty of the drawings fully merited some mark of approbation, they determined on presenting the draughtsman, Mr. Pinchback, with a bronze medal in testimony thereof.

The communications by Mr. Dempsey and Mr. Birch on Huddart's Rope Machinery, likewise called for some special mark of approbation on the part of the council. The liberality of Mr. Cotton, the intimate friend of the late Captain Huddart, proprietor of the machinery, in throwing open to the institution the works at Limehouse, is fresh in the recollection of most present; with that same liberality he at once acceded to the wish of the council, to allow any person to attend and make drawings of this celebrated Rope Machinery for the institution. Two young men availed themselves of this liberality, and with great perseverance measured and took drawings of this elaborate machinery, and the results of their industry are the two beautiful sets of drawings, accompanied by suitable manuscript accounts, presented by them to the institution. Of the accuracy of these drawings Mr. Cotton and Mr. Roberts have spoken in high terms; of their merits as mechanical drawings the institution has had ample opportunity of judging. The council felt that to have attempted to distinguish betwixt the merits of these two communications would have been both difficult and invidious, they have therefore awarded a Telford medal in silver, accompanied by books to the value of five guineas, both to Mr. Birch and Mr. Dempsey.

The council have already spoken of the liberality with which Mr. Cotton had responded to the wishes of the institution; his liberality stopped not, however, here, but he has promised to supply to the institution that account and history of this machinery of his late distinguished friend, which he alone has the power of doing.

On the other subjects then issued the council have not yet received any communications of great merit. They have, however, the pleasure of being able to announce that your associate Mr. Jones has made considerable progress with an account of the Westminster sewage, that your associate Mr. Johnson has promised some drawings and models connected with the Breakwater, and your member Mr. Oldham a communication on the means which he has adopted for warming and ventilation at the Bank of England. On the nature and properties of steam considered in reference to its application as a moving power, and on the ratio betwixt the velocity, load, and power of locomotive engines on railways, no communication to which a premium could with propriety be adjudged has yet been received. The subjects on which no communication deserving a premium has been received, have consequently been issued with others for the present session.

But though the council received no communication in which the subject of steam was treated in the wide and comprehensive manner which was desired, they deemed worthy of premiums the following communications on parts of this great subject. On the effective Pressure of Steam in the Cornish Condensing Engines, by your member, Thomas Wicksteed. On the expansive Action of Steam in the Cylinder of some of the Cornish Condensing Engines, by W. J. Henwood; and on the Evaporation of Water in the Boilers of Steam Engines, by your member, Josiah Parkes. To each of these the council have awarded a silver medal.

The communication by Mr. Wicksteed is of great value, as containing the only recorded experiment in which the water raised was actually weighed. It will be in the recollection of most present, that this is the second communication from Mr. Wicksteed on the same subject. The two are valuable additions to our knowledge on the subject. The water raised was weighed and measured. The weights raised in the stamping machinery were also accurately ascertained, and a comparison instituted between the duty of the single engine in raising water, and of the double-acting and crank engines in working stamps.

The communication by Mr. Henwood is remarkable for the extreme minuteness of detail with which the observations were conducted, the communication consists of two parts; the one, on the quantity of steam employed and the mode of its distribution on the working stroke, the other on the duty performed with a given quantity of fuel. Under the former the indicator is accurately described, and the evidence furnished by the diagrams explained. Under the latter is exhibited one of the most valuable specimens of detailed observations on record. It is a peculiar feature in the system pursued by Mr. Henwood, that he never interfered with the ordinary working of the engine; he observes with accuracy what is going on. Thus his paper is a record of observation in the highest sense of the term. It is of importance to practical men to keep in mind a distinction which has been often insisted on betwixt observation and experiment. In the former, the phenomena which are going on are noted as they go on, the circumstances under which they occur being untouched; in the latter, the phenomena are produced for the purpose of the experiment. The former consequently requires great care in referring effects to their proper causes, the latter in guarding against the results being influenced by the circumstances necessary for the production of the phenomena. The two are distinct, each requires their respective talents, the former would lead a Newton to the law of gravitation, and guide a Smeaton in the construction of an Edystone; the latter a Watt and a Black to a knowledge of the properties of steam; the two combined would guide a Davy to the construction of a safety-lamp.

In the communication of your member Mr. Parkes, we have an instance of both these methods combined; he observed what was going on under particular circumstances of evaporation, and then, having altered the circumstances, recorded the results of these experiments. The researches of this author led him to push slow combustion to its utmost limits. It would be foreign to the object of this report to trespass on the time of this meeting, further than to remark that the contents of this paper will furnish many most useful hints to the practical engineer in the management of the fires of his steam boilers, and to the theorist some important facts towards a true theory of combustion.

The council have also awarded a silver medal to the communications of your associate, Lieut. Denison, on the Strength of American Timber, and of your member, Mr. Bramah, on the strength of cast iron. Each of these communications must be viewed as valuable additions to our knowledge. The series of experiments by Lieut. Denison was undertaken by that highly talented officer, when stationed abroad, with a view of establishing some proportion betwixt the strength of different kinds of American timber, and of affording a means of comparing it with European. It is a peculiar feature in these experiments, that the effect of time in increasing the deflection is noted. After the elastic limit is passed the deflection increases with the time which the beam is loaded, the amount of this increase is recorded in most of these experiments. The council cannot but regret that Lieutenant Denison should have returned to this country before the very extensive series which he had contemplated, and for which he had made preparation was complete; his intention of determining the change of strength and the amount of shrinkage betwixt green and dry was thus unfortunately frustrated; and they most earnestly concur with him in the expression of hopes that officers and others employed in the colonies will be induced to turn their attention to this subject. They point out the above communication with especial pleasure as an example to other military engineers, of the very valuable services which their opportunities will enable them to render to the science of the civil engineer.

The other communication by Mr. Bramah is also a valuable addition to our knowledge, undertaken with a view of verifying the principles assumed in the widely-circulated work of Tredgold on Cast Iron; they surpass every other series in existence in their extent—the number of experiments being nearly 1500, and in the care taken to ensure accuracy, since two similar specimens of each beam were made the subject of experiment.

The principles, with the view of establishing which this series of experiments were undertaken, are, that the forces of compression and extension are equal within the elastic limit, and that consequently a triangular beam, provided it is not loaded beyond this limit, will have the same amount of deflection whether the base or apex be uppermost, and a flanged beam the same deflection, whether the flange be at the top or the bottom.

This communication is accompanied by some valuable observations by your associate, Mr. A. H. Renton, pointing out the agreement which subsists between the experiments and the results of the formula of Tredgold. The council have peculiar pleasure in pointing out the preceding, as communications of a kind on which they conceive the Telford medals may be most worthily bestowed. The undertaking a series of observations and experiments with a view of establishing important physical principles, and from a desire after the truth, is an object worthy of the highest approbation of this institution.

A silver medal has also been awarded to your member, Mr. Green, for his communication on the Canal Lifts on the Grand Western Canal; to your member, Mr. Harrison, for his communication on the Drops on the Stanhope and Tyne Railway, and to your associate, Josiah Richards, for his most elaborate drawing of the Rhymney Iron Works.

The perpendicular lifts erected by Mr. Green on the Grand Western Canal involve some ingenious applications of simple principles, and present many considerations of interest to the civil engineer. The principles of their construction are simple, and the economy of construction and saving both in time and water gives them great advantages in certain cases over locks for the purposes of canal navigation.

The Drops on the Stanhope and Tyne Railway for the purpose of shipping coals, present another instance of simple mechanical adaptation. These have several points in common with the lifts just spoken of; the original drawing of these by Mr. Harrison is an exceedingly beautiful example of what drawings of this nature ought to be.

Of the drawing of the Rhymney Iron Works by Josiah Richards, it would be difficult to speak in too high terms; it is a most elaborate drawing, exhibiting all the details of the manufacture of iron. The institution has not yet received the description which will be necessary to render the communication complete; but the council have the gratification of stating that your associate, Mr. Rowles, the chairman of the company, has promised that Mr. Richards shall be furnished with every facility towards completing a communication which, they doubt not, will be a most valuable acquisition to the records already existing in the institution.

The council have also awarded a silver medal to Francis Whishaw for his History of Westminster Bridge. Of the great labour and research of Mr. Whishaw in collecting these documents, it would be difficult to speak in adequate terms. The history is extracted from voluminous records contained in the Bridge-office, and you are indebted also to the kindness of your member, Mr. Swinburne, for the facilities which he furnished the author in the execution of his difficult task. The history of this bridge, the only one of the old bridges now remaining, is interesting to the general reader no less than to the engineer. The difficulties which presented themselves gave rise to contrivances then for the first time brought into use, of which the introduction of caissons is not the least remarkable. The difficulties and progress of the work are well set forth in the reports of Labelye, of which the more interesting are embodied in this communication; and the account of the work furnishes a very complete history of the state of this department of practical engineering a century ago.

This communication accompanied by an atlas of eleven drawings showing the site and various details of the construction of the bridge is one of those historical records which it is especially the object of this institution to collect, and which, from the labour and research employed upon it called for this mark of approbation of the council.

The institution received during last session from your member Mr. Rendel, a very elaborate and beautiful set of drawings, accompanied by a suitable description of the Torpoint Floating Bridge. This interesting communication is fresh in the recollection of most, and it would be difficult to speak in too high terms of the forethought, skill, and design, displayed in the construction of these bridges, and the perfect success which has attended their establishment. It does not often happen that the same individual has the genius to invent and the good fortune to see his invention brought into general use. In this respect Mr. Rendel has been singularly fortunate, as these bridges have been already established in several difficult and dangerous passages. It would be foreign to the present occasion to dwell more at length on this invention; but the council feel that in awarding a silver medal to Mr. Rendel, accompanied by a suitable record of the sense entertained of the benefit conferred by him on the inland communication of the country, this, the highest acknowledgment in their power to make, is most amply merited.

A bronze medal has been awarded to your associate, Mr. Ballard, for the drawing of his ice-boat, and description of his method of breaking ice by forcing it upwards; this simple method is applicable at about one-third the labour of the ordinary ice-boat. A bronze medal has also been awarded to Thomas Macdougal Smith, for his drawing and account of Edward's, or the Pont-y-tu-prydd Bridge, in South Wales. Mr. Smith being for a short time in the neighbourhood availed himself of this opportunity to make accurate drawings of this curious and interesting structure. The council would point out this as an example of the way in which every young man may, by availing himself of the opportunities afforded by his professional engagements, forward the objects which the institution has in view; and they would earnestly impress on all young men the importance of availing themselves of such opportunities, and of recording their observations on every work with which they may be connected. This habit is of the greatest advantage to the individual, since only by such an habitual self-improvement can any one hope to obtain eminence in the profession.

The council have also awarded five guineas to Mr. Guy for his method of making perfect spheres; this great desideratum in the mechanical art has been in a great measure supplied by the ingenuity of this individual, and a simple method furnished of readily producing spheres of metal, or other hard substance, with a great degree of accuracy.

The preceding are the communications of the last two sessions to which the council have awarded premiums. The council in disposing of the premiums placed at their disposal by the munificence of your late President, have endeavoured to select from the great number of communications which have been brought before the institution, such of each class as especially deserved this mark of distinction. They trust that these premiums may act as a stimulus to many, to forward to the institution records of matters of interest to the profession, and that thus the object of the noble benefactor of the institution will be fully realized.

The council cannot dwell on the numerous communications received during the last session, of which an ample account will be found in the Minutes of Proceedings, they cannot however omit to remark on the great interest of the discussions and on the value of the record of opinions and facts which is thus obtained. They would especially refer to the discussions on the duty of steam engines, and on the explosions of steam boilers, as having led to the collection of much valuable matter; the practice of recording the minutes of conversation is almost peculiar to your institution, and is calculated in an especial manner to forward the interests of practical science.

Life of Telford.—The council, in reviewing the events of the past year, cannot omit to express their gratification at the publication of the Life and Works of Telford. Every thing connected with his name is interesting to this institution, and the life and works of so distinguished a man, written by himself, cannot fail to be received with the greatest satisfaction by all who knew him or are able to appreciate his works. Through the kindness of your honorary member, Mr. Rickman, the editor of the life and works, and acting executor of Mr. Telford, the institution has been put in possession of two copies of this valuable work.

Monument of Telford.—The council have also the satisfaction of announcing through the medium of this report, that the monument to Telford is nearly finished, and that a place has been found for it in Westminster Abbey. The site which the Telford committee have selected and hope to obtain, is one well adapted for the statue, and they trust that by the next annual meeting the monument will be placed among those who, by the benefits conferred on their country, have justly deserved this tribute of respect.

Charles Tennant.—The institution has to regret the loss by death of Mr. Charles Tennant, of Glasgow, the eminent practical chemist. Mr. Tennant was born at Glenconna, in Ayrshire, in 1767, and commenced his career as an improver in the chemical arts before the end of the last century. The great revolution in the practice of bleaching which then occurred was carried out by the discoveries made by him, first of the solution of chloride of lime, and afterwards of the dry chloride of lime or bleaching powder,—an inestimable gift to the arts with which the name of Mr. Tennant will always be associated. The chemical works of St. Rollox, near Glasgow, which now form so conspicuous a monument of his energy and success, were erected for the purpose of manufacturing this article, for which he held a patent.

The manufacture of sulphuric acid, and of alkali from salt, was also greatly improved at St. Rollox, and first conducted there on a scale commensurate with their national importance. The manufacturing interests of this country possess an advantage in the extraordinary cheapness of these and other chemical products, which they owe in a great degree to Mr. Tennant's scientific talents, and activity as a manufacturer.

The arts are deeply indebted to Mr. Tennant for other benefits, particularly for his exertions in removing the duty on salt. This he ultimately succeeded in accomplishing, after a struggle of many years with the kelp proprietors. Few legislative enactments have been so beneficial to the country, as is well attested by the immense increase of alkali manufactories.

For some years past, Mr. Tennant left the chief management of his manufacturing affairs to his sons, and devoted a great portion of his energetic mind to the welfare of his fellow citizens, among whom he was considered a leader in every philanthropic undertaking.

The success of railway undertakings occupied latterly much of his time and attention; the last great struggle in which he was engaged was in favour of the Edinburgh and Glasgow line, the passing of the bill for which he had the happiness to live to see. He died at his house in Glasgow on the 1st of

October, aged 71, and has left a name which will long continue to be extensively known, and associated with practical science.

Presents.—The presents during the preceding year have been numerous and valuable, and the council have made several advantageous exchanges with other societies publishing transactions. From the Society of Arts, from the Geographical Society, and from the Society of Literature, the institution has received complete sets of Transactions. The Royal Society of Edinburgh, and the Philosophical Society of Manchester, have promised as complete a set as their stock will furnish.

The council have also to acknowledge the continued obligations of the institution to the Lord Lieutenant of Ireland, the Master General of the Ordnance, and Colonel Colby, for those maps of the Irish and English survey which have been published since the last annual meeting; they have also to acknowledge the liberality of your president in presenting that beautiful painting of the Menai bridge and adjacent scenery, which is placed in the library. They have also to acknowledge the liberality of your solicitor, Mr. Tooke, who has refused to accept any remuneration for the advice and information furnished to the council, accompanying his refusal with the most obliging expressions of the deep interest he takes in the welfare of the institution.

The following abstract of the receipts and expenditure, during the year ending the 31st of December, 1838, will show the present state of the funds of the institution:—

CASH ACCOUNT FOR LAST YEAR.

Telford Premiums		168	7	0
Balance		305	18	0
		£1620	10	9

It will be observed with satisfaction; that the balance in the hands of the treasurer, at the close of last year, was 305*l.* 18s. 10d., whereas at the close of the preceding year the balance was only 27*l.* 1s. 5d. The statement of this balance does not represent the funds of the institution in a sufficiently favourable point of view, as the amount of outstanding bills on the current expenditure at the commencement of the present year was considerably less than at the commencement of the last. The institution also possesses 335*l.* 3 per Cent. Consols, available for general purposes, and a lease of the house in Cannon-row, for which a good premium may reasonably be expected.

Conclusion.—In conclusion, the council cannot but offer to the meeting their sincere congratulations on the prospect which now lies before them. They congratulate the meeting on the recent accession of many names distinguished in their respective branches; and trust that the details of the preceding report not only attest their own unremitting attention, but also will be found to record many zealous and talented efforts on the part of the general body to promote the objects of the institution, and the progress of professional knowledge. From every quarter have been received the most liberal aid and sympathy—the most cordial co-operation. That by which you have been enabled to meet in the present more spacious and convenient premises will be readily appreciated.

The state of the funds is more prosperous than at any previous period; and in every point of view the present condition of the institution may form a subject of general congratulation.

The council now resign into your hands the trust committed to them, with a sanguine confidence in the future importance and dignity, as well as prosperity of the institution, and of its forming a national establishment for the advancement of professional knowledge, conspicuous even in an age of general improvement.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

The Ordinary Meeting was held on Monday, January 7, CHARLES BARRY, *Vice-President, in the Chair.*

The meeting proceeded to the election of the following gentlemen as Fellows:—Messrs. Ferrey, Walker, Wyatt, and Watson. As Associates:—Messrs. Brandon, Flower, Woodthorpe, Bury, Wright, Miles, Prichard, Peirce, and Eales.

Amongst the correspondence read, was a letter from Signor Nicolini, of Naples, accompanying an Italian translation of the several publications of the Institute, published by the Royal Neapolitan Academy of Fine Arts. These consisted of the constitution and by-laws of the Institute, the proceedings of the opening meeting in 1836, and the series of questions drawn up for the information of members, and which being thus circulated it was anticipated would lead to eliciting valuable information on architectural subjects from the Two Sicilies and the whole of Italy.

Mr. Richardson exhibited drawings of the Old and New Bethlehem, and there were also some interesting drawings of the architectural remains of the period of Elizabeth and James, from a collection in the museum of the late Sir J. Soane.

Donations were also announced from M. Valdermini, who has been employed in the reconstruction of the Imperial Palace at St. Petersburgh, which was recently burnt down; and from Mr. J. Wells, of drawings of the doorway of the famous Baptistry at Florence.

Mr. Fowler read a paper by Mr. Pocock, on the bond of brickwork, which occupied the remainder of the meeting.

Ordinary Meeting, Monday, 21st January, PHILIP HARDWICK, *Vice-President, in the Chair.*

The meeting proceeded to the election of the Signor Besia, architect, Professor of the I. and R. Academy of Brera, at Milan, as honorary and corresponding member.

The following donations were announced as having been received:—

Signor Cavaliere Gasse, hon. and corresponding member of Naples, three volumes, folio, of lithographed views in the Kingdom of the Two Sicilies.

Mons. Suys, hon. and corresponding member of Brussels, one volume of Illustrations of the Portico of the Pantheon at Rome, and prints of the Botanical Building at Brussels.

Mons. Leon Vaudoyer, Illustrations of the Monument to General Foy, erected by him in the cemetery of Pere la Chaise, Paris.

The following papers were read:—

Some observations on the heights of Entablatures, by Joseph Gwilt, Architect, F.S.A.

A description of the baronial castle of Sheriff Hutton, Yorkshire; illustrated by drawings, being a restoration sent in for the Soane medallion.

The thanks of the meeting were voted to Mr. Gwilt, for his interesting paper.

Mr. Catherwood, hon. and corresponding member of New York, being present, at the request of the meeting gave some explanation of the mode practised in America of transporting houses from one site to another, upon which the chairman conveyed to him the best thanks of the members.

ARCHITECTURAL SOCIETY.

At a Monthly Meeting, held at Lincoln's Inn Fields, on Tuesday evening, 15th January, 1839, WILLIAM TITE, ESQ., *President, in the chair,*

John Griffiths, Esq., Finsbury Pavement, was elected a member of the Society.

E. W. Brayley, jun., Esq., F.L.S., F.G.S., &c., delivered the first of a Course of Lectures; the subject of which was, "On the Geology and Mineralogy of Building Stones."

At the conclusion of the lecture, the President gave notice that the next public meeting would be held on Tuesday evening, the 12th February, when Mr. Brayley would deliver his second lecture—subject, "On Limestones and other Substances affording Materials for Cement;" and a third lecture on the 12th March—subject, "On Artificial Substances employed as Substitutes for Stone."

MEETINGS OF SCIENTIFIC SOCIETIES.

Royal Society and Society of Antiquaries, Somerset House, Thursdays, at half-past eight, P.M., 7, 14, 21, 28.

Institution of Civil Engineers, 25, Great George-street, Westminster, Tuesdays, at eight, P.M., 5, 12, 19, 26.

Royal Institute of British Architects, 16, Lower Grosvenor-street, Mondays, at eight, P.M., 12 and 26.

Architectural Society, 35, Lincoln's Inn-fields, Tuesday, at eight, P.M., 12.

Society of Arts, Adelphi, Wednesdays, at eight, P.M., 6, 13, 20, 27.

LAW PROCEEDINGS.

TITHE SURVEYS.

At the sitting of magistrates at Horsham, in December, a Mr. Baker, who is employed in surveying the parish of Lower Beeding, appeared to answer an information, charging him with having cut down certain trees and tellows, the property of R. Aldridge, Esq. The defendant admitted that he had cut down the trees, but pleaded that it was necessary to do so, in order to make a correct survey. After hearing evidence, the magistrates decided against the defendant, and fined him 5s., costs 40s. Mr. Baker intends to appeal to the quarter sessions.

DUTY ON GLASS.

An important case as affecting the manufacture of glass was brought before the magistrates of Sunderland last month, in an appeal by the Messrs. Hartley, glass-manufacturers of that town, against the amount of duty levied by the Excise. Messrs. Hartley, it appears, have recently taken out a patent for the manufacture of "broad glass," which bears a duty of £1 10s. per cwt.; but as the quality was found to resemble "German sheet," a superior kind of glass, which is chargeable with a duty of £3 13s. 6d., the excise officers made a surcharge on 80 cwt., amounting to £174. Mr. Wright, solicitor of Sunderland, who appeared for the appellants, conducted the case with great ability; and showed, by a reference to the act of Parliament, the distinction which the Legislature laid down as regulating the duties on glass. "Broad glass," chargeable, with the low duty of £1 10s. per cwt., was required to be annealed in an oven having but one opening, and the cylinder was required to be cut hot, whereas "German sheet" was allowed two openings to the oven, and the cylinder to be cut cold. By the introduction of various improvements, without infringing the clauses of the act of Parliament in reference to broad glass, Messrs. Hartley were enabled to manufacture glass bearing a close resemblance to German sheet. After a long investigation, the magistrates remitted the surcharge, thereby allowing the manufacturers to proceed, on payment of the smaller duty. Mr. Johnson, of Durham, appeared on behalf of the Crown. —*Newcastle Journal.* [It is a disgrace to the country that such obstacles should be put in the way of improvements in our manufactures. ED. C. E. and A. JOURNAL.]

STEAM NAVIGATION.

Great Western Steam Ship.—During her stay in the Royal Dock-yard at Milford great alterations have been made on board, all of which, we are assured, will very materially contribute to the comfort and convenience of the passengers. The whole of the lower berths under the saloon have been thrown into cargo space, and the passengers' berths reduced to a number which must ensure every comfort and accommodation. The house on deck has been removed, and in lieu thereof the cuddy has been carried forward more to the middle part of the vessel, and has a range of cabins on either side. The splendid saloon is lighted from upper skylights. Great additional room has been gained by the alterations, and a space under cover is obtained sufficient for a promenade for the whole number of passengers. The whole of the cooking establishment has been very much increased, and several other conveniences have been built on deck. The vessel, on examination, was found to be in the very best order, without even a single strain or so much as a ruck in her copper.

Steam from Glasgow to New York.—The merchants and manufacturers of Glasgow intend to try steam navigation to New York. They meditate, it is said, the building of an iron vessel, of very large dimensions and great steam power, to ply regularly between the Clyde and the Hudson.—*Scotsman.*

Steam from the Clyde to New York.—Glasgow is not to be behind Bristol or Liverpool in having a line of steamers across the Atlantic.—*Glasgow Chronicle.*

The splendid steam-ship Hecla, of 814 tons, was launched on the 14th January, at Chatham. This fine vessel was built under the superintendence of Mr. S. Read, from the School of Naval Architecture, Portsmouth, foreman of the shipwrights of this yard. This is the finest steam-ship ever built; her cabins, store-rooms, and indeed the whole of her fitments, are superb. She will carry two of those tremendous engines, eighty-pounders, on swivels, with four smaller guns.—*Maidstone Gazette.*

The last letters from Madras by the overland mail (the great irregularity of which has caused much complaint) mention that the association to promote steam navigation with Europe at that presidency has coalesced with the association at Calcutta, and that the united body will endeavour to promote the comprehensive plan of steam navigation between Europe and India.

The little wooden steam-boat, I told you some time ago was building at Cairo for the Pasha's use, was launched the other day there, and has turned out a very pretty boat. Another is ordered to be built immediately, and *the engines to be made in Cairo!*—another step in the progress of civilization in this country.

Novel Mode of Navigation.—The French Government steamer Veloce has been fitted out on a new principle for working the vessel with either sails or steam, and is now on her voyage from Rochefort to Mexico, for the purpose of testing this important invention. When fallen in with of late by a Spanish ship, north lat. 40°, long. W. of Paris 14°, the captain reported that her rate of sailing under topsails, studding-sails, and royals, had been for two days and a half upwards of eleven knots an hour.

France and America.—According to the plans proposed in its report by the committee of merchants of Bordeaux for the steamers to run between that port and New York, the vessels are to be 220 feet in the keel, width from 32 to 36 feet in the beam, and 21 to 22 feet in depth; they are to measure from 2,090 to 2,650 tons, are to be moved by engines of 450-horse power, and are to carry a crew of 67 individuals. The report calculates on an average of 60 passengers each trip, which would generally occupy 16 days, and the charge of passage is estimated at 1,000fr. The total capital required for the constructing and establishing one such vessel is estimated at 1,400,000fr., and the annual net profit resulting from seven voyages at from 200,000fr. to 280,000fr.

Spain.—A Barcelona letter of the 21st December states that the French merchants in that city had just presented a handsome sword to M. Gaufier d'Arc, the French Consul, in testimony of the good services he has so long rendered them. This gentleman, the letter adds, has forwarded to the Government at home a project for establishing a line of steamers to run from Marseilles to Barcelona, Cadiz, and the Canaries, thence to cross the Atlantic to Martinique and Cuba, and so to return home. Each vessel would carry engines of 200 horse power, would start the first day of each month, and, according to his estimate, would only cost 25,000f. on its voyage out and home.

Germany.—Arrangements are being made for extending the steam navigation of the Danube from Ratisbon to Ulm. If the undertaking succeeds, and there appears little doubt of it, the distance between these two cities may be performed in a single day, and from Ulm to Vienna in three days. This operation will open the Danube from its nearest navigable point to the Rhine, and thus offer the readiest mode of communication between London and Constantinople.—*Journal de Francfort.*

Holland.—Amsterdam, Dec. 29.—We hear that the English steam-boats will soon be obliged to come to Scheveningen. It is to be hoped for the sake of travellers that measures will be adopted to prevent the ground of complaint which existed last year.

The *Basle Gazette* says a second line of steamers is to be set up next spring between that city and Strasburg.

Gottingen.—A German paper gives the speech of the King of Sweden in reply to one of the numerous addresses presented to him in the course of his progress through his dominions. His Majesty told the authorities of Gothenburgh that he only awaited the concurrence of the British Government, to establish a regular communication by steam between Sweden and England.

PROGRESS OF RAILWAYS.

South Eastern Railway.—In the neighbourhood of Tonbridge the cuttings and embankments are proceeding with vigour, and a considerable quantity of brickwork, in culverts and occupation bridges, is completed and in progress. The culverts vary in diameter from 2 to 12 feet. At Dover the works are proceeding with great vigour. In another page of our present number will be found some particulars of the manner of carrying on the operations at this place.

Great Western Railway.—To make up for the time which has been lost on the Great Western Railroad near Reading, upwards of 100 extra workmen are now employed, who work at night by fire-light.

Manchester and Birmingham Railway.—The viaduct across the valley and river at Congleton has been let to Messrs. Nowell and Sons, Dewsbury, for £110,000. The length is 1030 yards, and the greatest height 98 feet 6 inches. It is to be finished in two years and a half.

Liverpool and Manchester Railway.—At the last half yearly general meeting of the proprietors of the Liverpool and Manchester railway, which took place on Tuesday, 22d January, in the Cotton Sales' Room, Exchange-buildings, the report stated that there had been an increased traffic in every branch as compared with the corresponding period in the preceding year; and that in the department of merchandise this result had been contributed to by the revival of trade from the depression under which it had laboured. Between Liverpool and Birmingham the traffic had also increased, and since the 31st of October last, the North Union railway had been opened for the conveyance of passengers, though arrangements for the transportation of goods had not yet been made, and perhaps no correct idea could yet be formed of the extent of the coach traffic from what had taken place in two months of the worst period of the year. The report concluded by stating that the directors intended to apply to Parliament, in the coming session for a bill empowering them to form a junction line, through the town of Salford, to Leeds. A draft of the bill would be drawn up and submitted to Parliament; and after the bill had been once read, the whole subject of the extension of the railway to Leeds, will then be brought before the proprietors.

The receipts for the half-year were:—

Coaching department	£79,277
Merchandise	54,215
Coals	3,200
Total receipts	£136,692
The total expenditure for the same period was	80,978
Leaving a balance of	£55,714

The largest items amongst the disbursements were—coach department, £11,051; carrying ditto, £11,189; coals, £743; engineering department, £26,427; carting £3,072. The accounts further stated that to the net profit of £55,714, there was to be added the sum of £853, being the balance after providing for last year's dividend, and thus making a total of £56,567. The total amount of shares were equal to 10,495 £100 shares; and the directors recommended that a dividend of £5 per cent. should be paid, which would leave a balance of £4,092.

ENGINEERING WORKS.

The Coffer Dam of the new Houses of Parliament was enclosed on the 24th of December last, since that time the men have been actively employed in clearing away the silt within the coffer; a fine stratum of gravel covers the whole site, and that part where the river wall is to be erected is now being excavated down to the clay substratum for the foundation, the dam stands remarkably firm, there are very little signs of leakage in any part of it. We shall, in our next number, give some account of the works in progress.

Dover, Jan. 13.—For the last few days past our harbour's mouth has been so completely choked up with shingle, in consequence of the prevalence of southerly and westerly gales, that all ingress or egress of vessels, foreign or domestic, may be said to have been entirely cut off. Even the small class of government packets have been compelled either to put into Ramsgate harbour, or to anchor in the Downs, there to await the precarious chance of our inefficient sluicing power enabling them to effect an entrance by the next tide. The sluices have been run to night. The only effect these playthings seem to have is to throw the beach in a heap a few yards beyond the pier-head at low water, that it may be thrown back into its old position each succeeding surge as the tide returns.

Caledonian Canal.—We are happy to learn that R. Steuart, Esq., one of the Lords of the Treasury, visited the Caledonian Canal lately, and we believe government seriously contemplates completing this great work, and rendering it suitable to the purposes originally contemplated, viz., to afford facilities of trade between the eastern and western coasts of the island, and the means of speedy and safe passage to vessels from the east coast of America, and the west coast to the Baltic. Even in its present state, we learn a good many vessels of this class have passed lately, and the trade is daily increasing. When tug steam boats are established, we have no doubt it will afford government an ample revenue. It should be recollected the Forth and Clyde Canal did not pay the original speculators for many years after it was opened, but it is now one of the most profitable public works in the country.—*Inverness Herald.*

Embankment of the River Thames.—At a late Court of Common Council, a report was presented from the Navigation Committee, recommending the embankment of the Thames, and regulating the line of wharfs on both shores of the river. The following letter, written at the desire of the corporation by Mr. Remembrancer, and addressed to Alexander Mylne, Esq., one of the Commissioners of Woods and Forests, fully explains the objects sought to be attained:—

"Guildhall, Sept. 17, 1838.

"Sir,—I am requested by the Navigation Committee of the Corporation of London to state to you, for the information of the Commissioners of her Majesty's Woods, &c., that the great inconvenience occasioned by the accumulation of mud near the embankment of the new Houses of Parliament renders it necessary that some immediate step should be taken to obviate the same, and that the Navigation Committee consider that the annoyance can only be effectually removed by continuing the line of embankment. Under these circumstances the Navigation Committee are of opinion that a survey and plan should be made of the river Thames, for the purpose of ascertaining the most desirable line of embankment on both sides of the river from London-bridge to Vauxhall-bridge, and also the expenses of making the proposed embankment, and of excavating and deepening the bed of the river where required; and that a bill should be brought into Parliament in the next session for embanking the river Thames, according to a plan to be agreed on; in which power should be given to the Commissioners of Woods, &c., to embank the bed and soil of the river opposite the crown property, and that power should be given to the corporation either to embank themselves, or to permit the owners of the wharfs and property on each side of the river to embank, under their directions, upon such terms as may, upon consideration, be thought desirable; half of the expense of the survey and of the act of Parliament to be borne by the Commissioners of her Majesty's Woods, &c.

"Alexander Mylne, Esq." (Signed) "Edward Tyrrell.

The Lords of the Treasury have agreed to the above propositions, and have appointed Mr. James Walker, of 23, Great George-street, Westminster, to make the necessary surveys and estimates. The Corporation have approved of the nomination of Mr. Walker, and have given him, as a colleague, Mr. Stephen Leach, the clerk of the works of the Thames Navigation.

Artesian Wells.—At a meeting of the St. Pancras vestry, a motion, proposed by Mr. Vigors, was carried, to the effect, that each member of the vestry should sign a declaration strongly approving of the plan of supplying the borough of Marylebone with water by means of Artesian wells.

Hastings.—The project of forming a harbour here has, after many weeks' agitation and excitement, been abandoned, so far at least as respects the idea of going to Parliament for a bill in the approaching session.—*Brighton Gazette.*

Mount's Bay Breakwater.—A very numerous and highly respectable meeting was held at the Town Hall, Penzance, on Tuesday, the 15th January, to take into consideration the propriety of memorialising her Majesty's government for the protection of life and property, and the promotion of important national objects, by the immediate construction of a breakwater in the Mount's Bay. It was stated that the breakwater would require 2,813,175 tons of stone, at 1s., being 140,658*l.* 15s., and for completing the slope, 1,108,529 tons at 1s. 3d., or 69,233*l.* 1s. 3d.—making the total cost, with ten per cent. for contingencies, 230,995*l.* 18s. 3d.

Menai Bridge.—So many contradictory reports have appeared relative to this noble structure, and particularly as to the degree of damage it has sustained in the late storm, that we are glad to avail ourselves of the communication of a friend, who visited the bridge on Thursday last. He writes:—"I have this moment returned from visiting the Menai Bridge, and have now the pleasure of acquainting you that the communication with Anglesea is again open; the mails, cars, and carriages, having passed over in perfect safety since Friday last. This applies, however, only to the division of roadway least injured by the hurricane—the other part is expected to be completed in a week or ten days. It is intended to strengthen, considerably, the vertical rods. The flooring, also, which was heretofore of common plank, four or five inches in thickness, will now be twelve and eighteen inches, and of Baltic timber. The broken vertical rods are being replaced, and part of the sunken flooring on the roadway, which suffered most, are completed. The main chains, which prove the stability of the suspension principle, have remained firm as the rocks in which they are embedded.—*Morning Chronicle.*

Portpatrick.—The late dreadful gale has considerably damaged the extensive works at Portpatrick, which our readers are aware have been carrying on for a considerable length of time at that place. In particular the pier-head, on which the harbour commissioners had erected a light-house, has been undermined; and the light-house is in such imminent danger, that the light-keeper narrowly escaped, and the light has since been transferred to the old tower, which is in a more sheltered position, in the interior of the harbour.

Scotch School of Engineering.—In the Scottish Naval and Military Academy is a professor of civil engineering and of the accessory branches.

Improvement of Leith Harbour.—Our readers will learn with much satisfaction, that the Lords of her Majesty's Treasury have been pleased to direct Messrs. Cubitt and Walker, jointly forthwith to proceed to Leith, regarding the projected improvement of the harbour; and we anxiously hope that the report of two engineers of such acknowledged ability and experience will put an end to all doubts and difficulties on the subject, in the minds of well-informed persons, and that after the report of these gentlemen is made, no farther obstacle from any quarter will be thrown in the way, that no partial interests or local prejudices will any longer be suffered to retard an immediate commencement of this long desired and necessary work for increasing the trade of the port of Leith, and promoting the prosperity, not only of the city and county of Edinburgh, but of a large portion of Scotland, that harbour being a great transit port. It is much to be wished that such energetic measures may be adopted by the engineers as will enable the commissioners to advertise in time for contractors, so that the work may be begun early in the spring. Not a day should be lost in securing the advantage of a low-water pier as near Leith as may be consistent with the general interests of trade and commerce.—*Edinburgh paper.*

Filtration of Water on a Great Scale.—In a recent number of the proceedings of the Institute of France, it is mentioned that a trial has been made of Fouvielli's filtering apparatus, working under the enormous pressure of 70 mitres, or nearly 230 feet of water. Four sets of apparatus, each about five feet high by three feet eight inches in diameter, have been set to work at Belleville and at La Villette. The water after passing through them possesses perfect limpidity, and it does not appear that this great pressure occasions any derangement of the filtering materials, whether the water be passing through them in the direction it takes in the process of filtration, or when the current is reversed during the time of cleansing, which occupies only a few minutes. The daily produce of the four filters is 177,408 gallons.

PUBLIC BUILDINGS AND IMPROVEMENTS.

Consecration of the New Church at Cheadle.—On Saturday last the new parish church at Cheadle was consecrated by the Lord Bishop of Hereford. It is a very splendid edifice, in the Gothic style, containing nave, side aisles, chancel and tower, at the west end, and will seat 1,500 persons. It is built by subscription.—*Staffordshire Gazette.*

The new staircase of *Buckingham Palace* is completed. It is more light and elegant than the former one, and gives access to the magnificent picture gallery. Some projected improvements have been deferred *sine die*, owing to the early return of the court to town.

Hyde Park.—A quadruple row of elms, forming three distinct malls, has just been planted, with much taste and judgment, at the eastern end of Hyde-park, and will, in a few years, add greatly to the beauty of that favourite resort.

St. Paul's Covent-garden.—The new school-house, erected in Hart-street, Covent-garden, cost nearly 2,000*l.*, towards which the Duke of Bedford has largely contributed. The school will comfortably accommodate, on three separate floors, 300 boys, 200 girls, and 200 infants, on week days; and 400 children are instructed by 35 gratuitous teachers, on Sundays.

The Late City of London Tavern.—The Wesleyan Methodists have purchased the City of London Tavern, Bishopsgate-street, for the sum of 15,000*l.* A part of the spacious building, which is freehold, is to be appropriated to meetings for business on their missionary and other benevolent undertakings; a portion being reserved for public worship.

The New National School of St. George the Martyr, Southwark.—The building is of Gothic architecture, consisting of a centre and two wings; the former comprises two school-rooms, one for the girls, and the other for the boys, calculated to hold upwards of 800 children. The wings will form residences for the masters and mistresses of the schools. The architect, Mr. White, spared no pains in making it a handsome and permanent building.

A New Road.—Application, it is said, will be made to Parliament, next session, of a bill for the purpose of forming a new road from Eaton-square to Kensington. The road is intended to cross Sloane-street, Alexander-square, and thence to the gardens of Gloucester Lodge, the residence of the late Mr. Canning; thence to the Addison-road; and to terminate at Kensington. The length will be two miles.

The Goldsmiths' Company, at their own expense, are about to erect a new church, adjoining their almshouses at East Acton, for the accommodation of the company's numerous tenants, and their aged poor in that establishment. The Bishop of London, as Lord of the Manor, presents them with a ring of bells and an organ.

Surrey Lunatic Asylum.—This building has been contracted for by Messrs. Baker at the sum of £39,370.—William Mozely, Esq., is the architect.

The equestrian statue of the Duke of Wellington, which excited so much attention at the Duke of Rutland's grand party at Belvoir Castle, was designed and modelled by Mr. Edmund Cotterill, and was manufactured by Messrs. Garrards.

Ascot Grand Stand.—The first stone of this building was laid on Wednesday last by Lord Errol, one of the trustees, in the presence of a large and distinguished company. The contract is taken by a Mr. Cuthill, who is under penalty to complete the structure by the 20th of May, so that the public may calculate on finding ample accommodation by the next meeting. The sum raised by 100*l.* shares is 10,000*l.*, part of which will be paid off yearly, until the stand is free, when it will become the property of the trustees for the benefit of the race fund.

Chester.—In consequence of the falling of a part of the buttresses from the tower of the venerable cathedral at Chester, the south transept was much injured, and the timbers burst through and broken to pieces.

Leeds.—A magnificent hall is to be erected in this town for the society of *New Odd Fellows*, from the designs of Messrs. Perkins and Backhouse, architects.

York Castle, the barracks, and the venerable cathedral, were injured by the late storm; in the latter, some of the valuable windows have been partially damaged, and such was the force of the wind that the lead roofing was driven a considerable distance from the building.

Birmingham, Storm.—The top of the Town-hall is roofed with lead, nearly three-fourths of which is torn off. A newly-erected chimney of the vitriol works, upwards, of 300 feet high, was partially blown down.

Dumfries, Storm.—Five stones have been displaced from the spire of St. Michael's and as it has long been off the plummet line, serious fears are entertained for its future safety. The same remark applies to the wooden top of the Mid-steeple, and all the churches on both sides of the river have been more or less damaged, not excepting St. Mary's.

Dublin, Storm.—The ball which surmounted the spire of St. Patrick's Cathedral was blown down, providentially without doing mischief. It had been out of perpendicular a considerable time, and fell within the railing in the North Close. About 27 years ago the former ball fell, carrying with it several feet of the spire.

Ireland.—The Earl of Dunraven is completing a magnificent mansion at Adare Abbey, upon which 40,000*l.* will have been expended. Lord Clarina is making an outlay of 10,000*l.* upon valuable improvements at the hereditary seat, Elm-park. William Munsell, Esq., has commenced large improvements at the ancient mansion and romantic demesne of Tervoe. General Lord Bloomfield, a beautiful mansion and villa near Newport. Sir Lucius O'Brien, Bart., still further embellishing the splendid residence of his ancestors, at Dromoland. Mr. Barrington building a mansion at Cannercullen.—*Limerick Chronicle.*

The Juvenile Prison at Parkhurst, Isle of Wight, being now finished, received its first fifty inmates in December, from the hulks at Portsmouth.

FOREIGN INTELLIGENCE.

Paris.—The commission which was appointed to examine and report upon the new fire-proof machinery (consisting of Col. Paulin, M. Rohault, M. Maynich, and M. Simonet) met on Friday, Jan. 11th. Their instructions are to furnish a report, with a view to the introduction of this *perfectionnement* in theatrical mechanism, as well into the proposed new theatres as into those already constructed.

The large paintings in the church of the Madeleine, by Messrs. Ziegler, Abel de Pujol, &c., are nearly finished; the sculpture, gilding, and incrustations in marble are almost completed; the altars, pulpit, baptistry, and *banc d'œuvre* are nearly placed; and the great bronze doors are rapidly approaching to completion. It is expected that the building will be inaugurated in the fêtes of next July.

New French Copyright Bill.—The author of a drawing, picture, a work of sculpture, architecture, or any other work of the same description, shall alone have the right of reproducing or authorising the reproducing of it, by engraving, or in any other way. This right shall last during the author's whole life. After his death, his widow, heirs, or representatives shall enjoy it, conformably to the provisions established in the first paragraph of this present law. The authors of the works just mentioned, or their representatives, may cede the right secured to them, retaining, nevertheless, the property of the work; but, in case the original work be sold, the exclusive right of authorising the reproducing of it by engraving or any other means shall be transferred to the purchaser, if no stipulation to the contrary exists.

Immense wooden galleries are now being erected in the square of the Champs Elysées, for the impending exhibition of the produce of French manufacture.

Naples.—According to letters from Palermo of the 24th Dec., referred to in *Le Commerce*, the King of Naples, previous to his departure from Sicily, published a variety of decrees relative to the establishment of cemeteries, without the precincts of towns, the opening of a number of roads, &c.

Napoleon Column.—The *Journal de la Corse* states, that the works on the column which is to be erected in honour of Napoleon, near the house in which he was born at Ajaccio, are going on with rapidity. The column will be formed of a single block of the granite of the country 50 feet long, and will be surmounted by a statue of the Emperor.

Dutch Dikes.—In the island of Beverland, which is only fifteen miles in length by seven in breadth, there are 200 miles of dikes or artificial embankments.—*Chambers' Edinburgh Journal.*

Steam Dock-yard in Holland.—About a mile above Rotterdam, on our right, we noticed Finjord, a considerable steam building station, where at present a large number of men are employed, many of them upon an iron steam-boat of great magnitude.—*Chambers' Edinburgh Journal.*

Bruges Road.—A new road is in the process of construction betwixt Bruges and Calais. It will be much shorter than any other now existing, and direct, except in one part, where, on account of the mobile nature of the gravelly soil, a circuit of three miles is rendered unavoidable.

Haarlem Lake.—It seems that there is a very great diversity of opinion in the sections of the two chambers respecting the project for draining the Lake of Haarlem.

Hamburgh.—A private letter states that during the late tremendous gale, the harbour of this place had been almost entirely destroyed, nearly every pile having been torn away; the whole town had been inundated.

In the dominions of the King of Wirtemberg a royal theatre is to be built at Stütgard, and a smaller theatre, to be completed next year, at Kanstadt, within a few miles of the former town. Professer Zaüht, who lately visited England, is the architect of the new theatres.

A grand theatre is about to be built at Dresden, at the public expense, for the performance of German and Italian operas.

The Statue of Goethe, executed at Milan, arrived a few days since at Frankfort.

The celebrated Bavarian painter, M. Cornelius, who has lately visited Paris, has been made a Knight of the Legion of Honour, and since elected Foreign Associate of the Royal Academy of the Fine Arts, in lieu of the late distinguished composer, Zingarelli.

Copenhagen, Jan. 5.—The King has removed the principal obstacles to the erection of the Thorwaldsen museum, by alloting to that purpose a building consisting of two wings, and another portion of the palace of Christianburg.

Greece.—An advantageous discovery for the state has been lately made in the mines of Kumi, a better sort of coal than that as yet worked having been found.

Road to the Red Sea.—We learn by letters from Alexandria, that 800 Europeans crossed the isthmus of Suez last year, on their passage to and from India; and that a regular coach conveyance will be soon established between the shores of the Levant and the nearest point for embarkation on the borders of the Red Sea.

Pennsylvania Public Works.—The amount expended in 1837, by the state of Pennsylvania, in public works, was, for canals and railways, 1,733,442 dollars, and for turnpikes, 118,160 dd., being about 400,000*l*. The receipts were, canal lotts, 415,681 dols., railway lotts, 335,827.

NEW PATENTS.

LIST OF ENGLISH PATENTS GRANTED BETWEEN THE 24TH OF DECEMBER, 1838, AND THE 29TH OF JANUARY, 1839.

Samuel Clegg, of Sidmouth-street, Gray's Inn-road, Engineer, for "A new Improvement in Valves and the combination of them with Machinery."—3rd January; 6 months to specify.

Henry Robert Abraham, of Keppel-street, Russell-square, Architect, for "Improvements in Apparatus applicable to Steam-boilers."—3rd January; 6 months.

Thomas Nicholas Raper, of Greek-street, Soho, Gentleman, for "Improvements in rendering Fabrics and Leather Waterproof."—3rd January; 6 months.

Abel Morrall, of Studley, Needle Maker, for "Certain Improvements in the Making or Manufacturing of Needles, and in the Machinery or Apparatus employed therein."—3rd January; 6 months.

Louis Mathurin Busson du Maurier, of Lombard-street, Gentleman, for "Improvements in the construction of Springs for Carriages."—3rd January; 6 months.

Miles Berry, of Chancery-lane, for "Certain Improvements in Rotatory Engines to be worked by Steam or other Fluids.—4th January; 6 months.

William Hickling Burnett, of Wharton-street, Bagnigge Wells-road, Gentlemen, for "New and Improved Machinery for Sawing, Planing, Groving, and other preparing and working Wood for certain purposes."—8th January: 6 months.

Joseph Clisild Daniell, of Limphey Stoke, Wilts, for "An Improved Method of weaving Woollen Cloths and Cloths made of Wool together with other materials." —9th January; 6 months.

Moses Poole, of Lincoln's Inn, Gentleman, for "Certain Improvements in Clogs." —11th January: 6 months.

John Howarth, of Aldermanbury, Manufacturer, for "Certain Improvements in Machinery in Spinning, Roving, Doubling, and Twisting Cotton, and other fibrous materials."—11th January; 6 months.

John Ashton, of Manchester, Silk Manufacturer, for "An Improvement or Improvements in Manufacturing Plush of Silk or other fibrous materials."—11th January; 6 months.

John Swain Worth, of Manchester, Merchant, for "An Improved Machine for Preparing and Cleaning Wool for Manufacturing Purposes."—11th January; 6 months.

William Newton, of Chancery-lane, for "Certain Improvements in Machines for Drilling Land or Sowing Grain and Seeds of different descriptions."—11th January; 6 months.

Francis Brewin, of the Old Kent-road, Tanner, for "Certain Improvements in using Materials employed in Tanning, and preparing the same for other useful purposes."—11th January; 6 months.

Robert Logan, of Trafalgar-square, for "A new Cloth or Cloths constructed from Cocoa Nut Fibre, and for certain Improvements in preparing such fibrous materials for the same and other purposes."—11th January; 6 months.

William Ponsford, of Wangye-house, Essex, gentleman, for "Improvements in the Manufacture of Hats, and an Improved Description of Felt suitable for Hats and various other useful purposes, and Improvements in preparing the Material or Materials chiefly used in the Manufacture of such felt."—Jan. 12; six months.

Edwin Marten, of the village of Brasted, Kent, plumber, for "An Improved Method of Laying covering composed of Lead or other Metal on the Roofs of Houses or other Buildings, with Drains, whereby the part of the Water falling on such roof which would otherwise penetrate, is carried off, and rolls and seams are rendered unnecessary."—Jan. 12; six months.

Joseph Burch, of Bankside, Blackfriars, calico printer, for "Certain Improvements in printing Cotton, Woollen, Paper and other Fabrics and Materials."—Jan. 15; six months.

William Witham, of Huddersfield, machinist, for "Improvements in Engines to be worked by Steam-water or other fluids."—Jan. 15; six months.

Hugh Ford Bacon, of Fen Drayton, Cambridge, for "Improvement or Improvements in Apparatus for regulating the Flow or Supply of Gas through Pipes to Gas Burners, with a view to uniformity of supply."—Jan. 17; six months.

William Holme Heginbotham, of Stockport, gentleman, for "Certain Improvements in Machinery or Apparatus for propelling Boats or other Vessels, to be employed either for Marine or Inland Navigation, and to be worked by steam or other power."—Jan. 17; six months.

William Newton, of Chancery-lane, Civil Engineer, for "Certain Improvements in Engines, to be worked by Air or other Gases."—Jan. 17; six months.

Oglethorpe Wakelin Barratt, of Birmingham, Metal Gilder, for "Certain Improvements in the process of decomposing Muriate of Soda, for the Manufacture of Mineral Alkali and other valuable products."—Jan. 19; six months.

Joseph Garnett, of Haslingden, Dyer, for "Certain Improvements in Machinery or Apparatus for carding Cotton, Flax, Wool, or any other fibrous substances."—Jan. 19; six months.

Richard Dugdale, of Paris, now residing at Manchester-street, Middlesex, Engineer, for "Method or Methods of increasing the security, tenacity and strength of Beams, Axles, Rods and other articles made of Iron and Steel."—Jan. 19; six months.

Caleb Bedells, of Leicester, Manufacturer, for "Improvements in Gloves, Stockings and other Articles of Hosiery."—Jan. 21; two months.

John Coope Haddan, of Baring-place, Waterloo-road, Surrey, Civil Engineer, for "Improvements in Machinery or apparatus for propelling Vessels and Boats by Steam or other power."—Jan. 22; six months.

George Stevens, of Stowmarket, Brewer, for "Certain Improvements in Stoves."—Jan. 22; six months.

Thomas Dowling, of Chapel-place, Oxford-street, gentleman, for "Improvements in preparing Metals for the prevention of Oxidation."—Jan. 24; six months.

John Harrocks Ainsworth, of Halliwell, Lancaster, Bleacher, for "Certain Improvements in Machinery or Apparatus for Stretching, Drying and Finishing Woven Fabrics."—Jan. 24; six months.

Robert Copland, of Courland, Wandsworth-road, Surrey, Esquire, for "Improvements in Water-wheels."—24th January; 6 months.

Pierre Jean Isidore Verdure, of the Sabloniere Hotel, Leicester-square, Gentleman, for "Improvements in the Manufacture of Starch, and in the Machinery for preparing and in employing of the refuse matters obtained in such manufacture." —25th January; 6 months.

John Howard Kyan, of Cheltenham, Esquire, and William Hyatt, of Lower Fountain-place, City-road, Engineer, for "Improvements in Steam Engines."—29th January; 6 months.

John Hillard, of Bread-street, Cheapside, Merchant, for "Certain Improvements in Machinery and Apparatus for Making and Manufacturing Screws."—29th January; 6 months.

William Lukyn, of Lower Cowley House, Oxford, Dentist, for "Certain Improvements in applying and attaching Artificial and Natural Teeth."—29th January; 6 months.

TO CORRESPONDENTS.

We have received several communications on the subject of engineering education. We had conceived that we had gone into the subject at sufficient length, but as these communications call for a reopening of the question we intend to go into it at greater extent next month. We had commenced a reply this month, but on account of the pressure of matter we are obliged to defer it until the next number.

We regret that we are obliged to postpone Mr. Tait's communication on Improvements in Railways. Likewise several other communications. We will endeavour to make up the arrears in our next journal.

In reply to the inquiry of the Country Subscriber respecting the Oxford-street pavement, we must observe that each party has laid down his specimen at his own expense, and that the present experiment is not to try the expense but the durability and working of the different systems.

Subscribers are particularly requested to complete their sets of numbers for the first volume immediately.

We shall feel obliged to the profession if they will forward us accounts of works in progress, new inventions and discoveries; and particularly if our country subscribers will send us any newspaper containing any matter relative to the objects of our Journal.

Books for review must be sent early in the month; communications prior to the 20th; and advertisements before the 26th instant.

⁂ The first volume may be had bound in cloth, and lettered in gold, price 17s

Fig. 16. Elevation of one of the external lengths of the tubular ribs of cast iron, 13 feet 9 inches long, and 2 feet 9 inches deep, including flanges.

Fig. 17. Elevation of the inside ribs, showing the section of the bolts and ribs.

Fig. 18. Plan of top of one of the ribs, showing the edge of the flanges and connexions.—A, iron tubular rib.—B, cast-iron hollow cylinders, 4½ inches diameter, forming stays between the ribs.—C, wrought-iron bolts or ties, 1½ inches diameter, with nuts and screws.—D, cast-iron diagonal braces, with feathers, average 9 by 5½ inches, and a groove at the ends, fitting on, and bolted to the connecting pieces, screwed to both sides of the upper flange of the tubular ribs; similar letters refer to similar parts in figure 17.

Fig. 19. An enlarged section of rib, drawn to a scale of two inches to the foot. A, cast-iron casing.—B, nine thicknesses of timber, bent into a curvilinear form, and bolted together with nut and screw bolts, C C.—D, coating of asphalte.—E E, nut and screw bolts, connecting the two cheeks of the iron rib, with thin slips of wood between the flanges.—F, capping of asphalte.—G, lower part of one of the iron rings, which carries the longitudinal bearers, as shown in fig. 4.

This bridge was constructed under the direction of M. Polenceau, engineer. It was commenced in the year 1834, and completed in 1836. It forms a communication over the Seine, between the Place du Carrousel by the Quai du Louvre and the Quai Voltaire. The bridge presents some novel features in its construction, so as to merit the attention of the profession. It is constructed of timber and iron, with stone-cased piers and abutments. The bridge consists of three arches, forming portions of an ellipsis. One only is shown in the accompanying drawings. The centre arch is 187 feet span, and 16½ feet rise; and the two side arches 156 feet span, and 15½ feet rise. The total length of the bridge, including piers and abutments, is 558 feet, and the breadth of the roadway 35 feet. The whole length of the bridge in its design forms a flat arch. The chord line of the side arches is slightly removed from the horizontal, so that a line drawn from the springing at the pier to the springing at the abutment would make an angle of one degree with the horizon. The chord of the middle arch is horizontal.

The piers are cased with hewn sandstone, and filled in with concrete. They are also erected on a foundation of concrete, and protected with sheet piling. The cut-waters at each end of the piers are semi-circular, and are thus carried up to a level with the springing of the arch, and terminated with a hemispherical head. Above that level the piers are carried up square, and project about 1 foot 8 inches before the face of the arches. The abutments are also cased with stone, and founded on concrete. On account of the flatness of the bed of the river, they are projected forward on each side, so as to concentrate the stream in the centre of the river. By reference to the drawings it will be seen that the cornice of the abutments and piers follow the inclination of the roadway, which we consider an improvement in the architectural effect on the ordinary mode of making the cornice and parapet horizontal, as at London, Waterloo, and other bridges.

We will now proceed to describe the construction of the arches. It will be observed that at the springing of the ribs the abutments are splayed or inclined to an angle of 66 deg., and formed of solid masses of stone, on the face of which oval recesses are sunk to receive the abutment plates, and are made a little larger, to prevent the vibration of the bridge splitting the stone off the edges. The abutment plates are of cast-iron, in two pieces, as shown in figures 7 to 13, which were firmly bedded on to the stone with *Pouilly* cement. These plates form a socket for the reception of other plates bolted on to the ends of the ribs. They were firmly connected together, and the joints filled in with an iron cement, composed of 10 parts of cast-iron filings, 2·5 of sal ammoniac, 1·8 of sulphur, and 2·25 of metal dross. All these were in fine powders, carefully amalgamated, and mixed with only enough water to bring them to a good consistence. The weight of each under plate is about 850lbs., and of the upper plates 1220lbs.

In order to unite the firmness of iron with the elasticity of wood, and to insure both against the ravages of the weather, while lightness and cheapness of construction are equally consulted, M. Polenceau has adopted a peculiar form of rib, which has been called, from its shape, the "tubular rib." Each rib is formed in 22 lengths, and composed of two separate cheeks of cast iron, bolted together, with nine thicknesses of timber inside, as shown in figure 19. The interstices between the timber and iron are filled in with a composition of two parts of Seyssel asphalte, and one part of gas tar, which also forms a capping on the top of the ribs. In filling in the asphalte, the ribs were heated by means of portable furnaces, so that an opportunity was afforded of ascertaining the extreme expansion of the metal. The length of the ribs were of four kinds—outer and inner end pieces, and outer and inner middle pieces, varying in size, but were about 13 feet long on the average, and weighed about 2,800lbs. To insure their strength, each half rib was subjected to a double proof, first by suspending it by a fulcrum at each end, and then laying on it 40 tons; and again, by dropping a ton and a half on the middle, from a height of 1, 2, 4, and 6 yards: these lengths fit into each other, and are fastened together by screw-bolts and iron keys, as shown in figures 16 and 17.

Each arch is composed of five ribs, connected together by means of cross ties, bolts, and braces, as shown in figures 2 and 3, and more at large at figures 17 and 18: upon these ribs are placed the rings which carry the superstructure; they vary in size and weight, according to their position. Some of the larger are 10 feet diameter, and a ton and a half in weight; they are united to each other by bolts at their circumferences, as shown in figures 14 and 15. By reference to figure 19, it will be seen how the lower part of the ring rests upon the ribs; and, by figure 4, how the upper part carries the longitudinal bearers: these rings are again connected transversely, by means of bolts across the arch. They required considerable care in setting them, on account of the difference in the size of the arches. Some of them were found too large, and others too small.

The longitudinal bearers or girders consist of two flitches of oak, bolted together, as shown in figure 4: upon these are laid the transverse bearers or joists of oak, which are notched or calked, and bolted down; upon the joists are laid two thicknesses of planks, breaking joints over each other. The lower planks are of oak, and the upper of deal; over these are laid the road materials, and on the sides are flitches of timber, forming a curb and gutter to the roadway; the footpath is also formed of oak plants, raised on longitudinal bearers, as shown in figure 4, with a slip of iron let in flush, the whole length, and iron guards at distances, as shown in figure 4. The exterior of the footpath is converted into a cornice, an iron sunk fascia, being laid over the face of the lower longitudinal bearer, and on the ends of the joists, an iron capping, forming a modillion, with a moulded capping also of cast iron, and the upper part formed into a fascia with a bed molding under the edge of the footpath, the whole having a pleasing effect, as shown in figures 4 and 5. The plankings of the roadway were well rubbed over with tar, and all the joints carefully filled up with sand, and then rubbed with a mixture of equal parts of vegetable and gas tar. The material of the road is composed of white chalk stones and pebbles, the size of walnuts, and the whole surface of the roadway and footpaths finished with asphalte. On each side of the bridge, to protect the footpath, is an iron railing, with bars 7 inches apart. All the iron work of the bridge is painted with an iron grey colour, of M. Polenceau's invention.

We have endeavoured to explain the construction of this bridge in the best manner we are able, and for the better understanding of its details, we refer the reader to the drawings and references which will be found to contain the dimensions of most of the timber.

We are principally indebted for the drawings to our foreign contemporary, the "Algemeine Bauzeitung." We wish the editor of that publication would be as generous in acknowledging the numerous articles that have been copied by him from this journal.

GLENARM HARBOUR.

"The chief ruler or statesman that will be able to form asylum-harbours on the unsheltered and dangerous parts of the coast, and will also cause to be marked or beaconed, by the erection of granite towers, the dangerous rocks, the shoals, and the reefs which surround the shores of these kingdoms, thereby giving safety and security to the mariner in time of tempest and storm; also safety to the floating wealth of these realms, and the colonies thereunto belonging; also lessening the wail of the widow and the orphan throughout this maritime land—will not only receive the blessings of future generations for the erection of these works of mercy, tending so much to the preservation of life and property, but will also increase, to a great extent, the wealth, the power, and prosperity of the whole empire."—*Bald's Evidence on Harbours—Public Works—Ireland.*

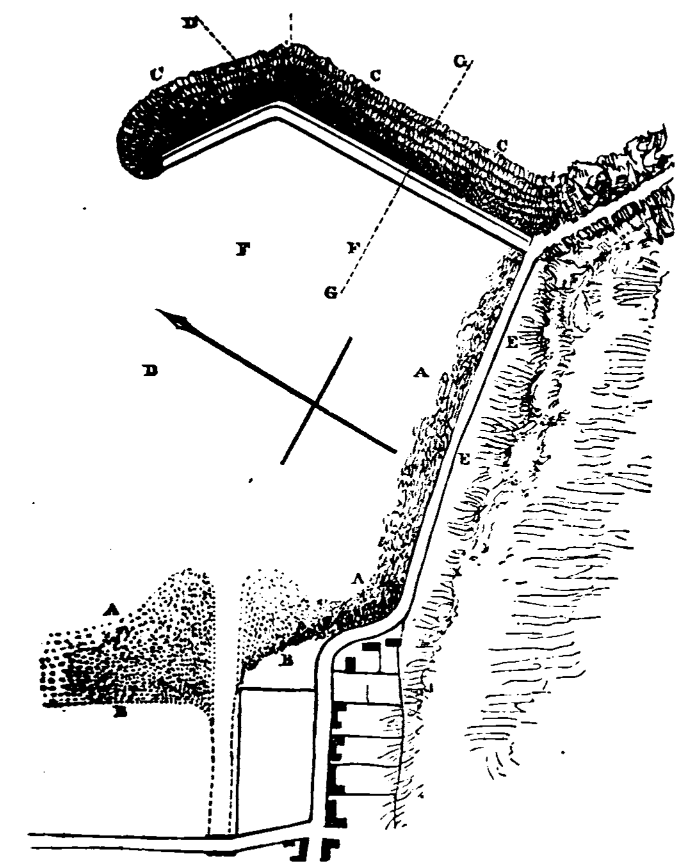
Report of William Bald, Civil Engineer, F.R.S.E. & M.R.I.A., &c., *on the erection of a Pier, and formation of a Harbour in Glenarm Bay, in the County of Antrim, Ireland.*

The Bay of Glenarm, where the proposed Pier is intended to be erected, is situated on the north-east coast of the county of Antrim, bordering the North Channel. The bay is about half a mile in length, and three furlongs in breadth; containing an area of about 120 acres, and possessing a very considerable depth of water: four, five, aud six fathoms. The bottom consists of clay, and is well known to be excellent holding-ground to all classes of ships. At the head of Glenarm Bay is situated the town of Glenarm, and the land surrounding the bay rises to a considerable elevation, and protects it from the prevailing southerly and westerly gales. This bay is, however, open to the channel sea from the north, north-east, east, and south-east; but the greatest run of sea into it is from the north and north-east. The Bay of Glenarm lies nearly opposite the entrance to the Clyde, offering very great facilities to commercial intercourse with all the towns situated on the west of Scotland; viz., Glasgow, Ayr, Greenock, &c. &c. It is distant from Larne 10 miles, and from Portrush nearly 50 miles; so that, in an extent of 60 miles of coast, there is no harbour, either artificial or natural, to afford protection to foreign traders, coasting vessels, or even to the smallest description of fishing craft. These reasons alone are sufficient to prove the great utility that would be derived from the erection of a harbour in Glenarm Bay; and it would, also, give shelter and security to a great portion of the floating wealth belonging to the Clyde, the port of Liverpool, the colonies of North America, and the West Indies, which would pass through the Irish Northern Channel. Besides affording an asylum for vessels overtaken by storm, it would give a port to the whole of the central portion of the county of Antrim, consisting of large districts of country highly cultivated, and producing great quantities of grain, and cattle of all kinds, and which could be cheaply exported, by means of a harbour at Glenarm; and, also, the valuable facility of importing into the country all the necessary articles of merchandize. Glenarm harbour would become the port to an extent of country containing not less than 400 square miles, also to the whole of the fertile interior country adjacent to the large and populous town of Ballymena, distant only 12 miles; and it would offer a ready means of direct commercial intercourse with the manufacturing and maritime districts of the Clyde in Scotland, both by steam and sailing vessels; and which would, in a very short period, create and augment the trade of the country to a very great extent. The Portrush and Derry steamers to Liverpool, touching at Glenarm, would establish a trade of vital importance to the merchants of Ballymena, particularly those engaged in the export of pork, butter, provisions, and linen cloth. The exportation of limestone from Glenarm to Scotland, and the importation of coal in return, would form a very lucrative and highly beneficial branch of trade between the countries. At present there is not more than about 6,000 tons of limestone exported, and only 1,000 tons of coal imported. There can be no doubt but the importation of coal would greatly increase, both for burning lime, and working the steam-engines and machinery in progress of erection at Ballymena and Broughshane, when the facility of procuring this necessary article from Britain is attained, by the construction of a harbour at Glenarm.

The port of Belfast is distant from Ballymena about 24 miles, and Glenarm is only 12 miles; and independent of the saving of land-carriage, it offers a greater facility to direct intercourse with Scotland, being nearer, and in a more direct line; besides, the depth of water within the proposed pier at Glenarm would enable vessels drawing even more than 20 feet of water to enter and depart at all times of tide. With these eminent and peculiar advantages, which no artificial harbour in Ireland possesses except two, there can be no doubt but a very considerable trade would arise, fully sufficient to repay any moderate expenditure which might be made in erecting a pier at Glenarm Bay.

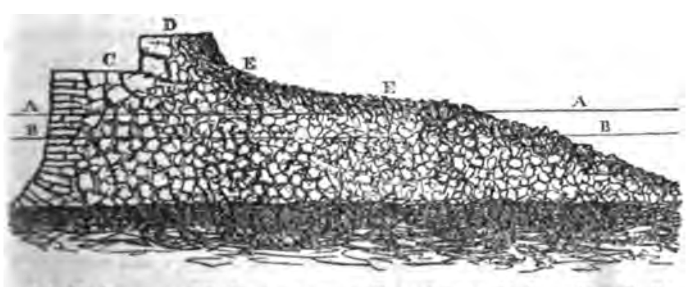
Design for a Harbour at Glenarm on the Coast of the County of Antrim, Ireland. Drawn to a scale of 800 feet to 1½ inch. By WILLIAM BALD, F.R.S.E., M.R.I.A., and Civil Engineer.

Fig. 1. Plan of Harbour.



(The dotted line D)—N. by E ½ to the Mull of Cantire—(the other dotted line)—NE by E ½ E, to Craig of Ailsa—AAA, Low-water—BB, High-water—CCC, Proposed Pier or Breakwater—DD, Glenarm Bay—EE, Roadway—FF, Harbour—GG, Line of Transverse Section—H, Town of Glenarm.

Fig. 2. Transverse Section at GG, 190 feet broad at base; drawn to a scale of 55 feet to the inch.



AA, High-water—BB, Low-water—C, Top of Quay, 18 feet wide—D, Parapet at top, or Storm Pavement—EE, Breakwater Glacis, or Storm Pavement.

The Construction.—It is proposed to run out a rough pier, or breakwater, from Paixe's Point to a distance of 825 feet, then with a cant of 380 feet in length, as laid down, drawn and described in the chart containing the proposed design and sections of the breakwater, deposited with the clerk of the peace. This work would effectually protect and cover about 20 acres of the Bay of Glenarm, and give security and shelter to trading ships of all kinds. The depth of water within the mole would be from 22 to 30 feet at high water ordinary spring tides. There is an abundance of limestone, in extremely thick beds, lying close to the proposed site of the breakwater, easily wrought, and which will afford an abundance of very heavy and large material, at a remarkably cheap rate, to construct the breakwater with. It is proposed, simply to lay down an abundance of stone blocks, and then to permit the ocean, for some time during storms, to shape down the slopes of the sea-side of the mole to the angles of inclination which the momentum of that element would assign to such materials. And for the purposes of landing and shipping of goods, it is intended to construct a timber wharf within the pier or breakwater, leaving to some future period, when the trade would afford the means, the facing up of the inside of the pier with squared masonry. Even the construction of only 300 or 400 feet in length of the breakwater, would enable vessels to discharge and take in cargoes, so that an *immediate* traffic would be the result of even a very small portion of this work being done.

I have drawn out two estimates: one for an extension of 1,205 feet in length—amount, £17,312 16*s.* 8*d.*; the second estimate is for an extension of, in length, 825 feet—amount, £11,217 2*s.* 5*d.*

WILLIAM BALD, *Civil Engineer.*

RALPH REDIVIVUS.—No. XIV.

THE LOWTHER ARCADE.

What advantages its more successful rival may possess in regard to its shops, I am not prepared to say, neither is it a question of any importance to my present purpose, but I may assert, almost without fear of contradiction from any one, that the Lowther as far surpasses the Burlington Arcade in its architectural appearance, as it falls short of it in the degree of favour and patronage it receives from the public. In itself this is but very indifferent praise, since it might be greatly superior to the other, and yet scarcely worthy of notice for any architectural merit. In fact, as a design, this piece of architecture displays both originality and taste, greatly more so than many things which it is the fashion to talk of, merely, it would seem, because they happen to have been cried up in books, and their praises have been repeated and handed down from one book-maker to another, without further examination or inquiry.

Before, however, I touch upon the merits of this arcade, I must be allowed to say something in regard to the class of buildings so denominated in this country. As far as public convenience is concerned, most assuredly nothing could be devised more suitable to such a climate as ours—that is, supposing it to deserve one tithe of the ill-natured, splenetic grumbling it provokes,—than a covered street, which bids defiance to the humours of the atmosphere, and where one may lounge and look at the shop-windows, though the rain should come down in torrents, or though an August sun should broil people as they walk along in the open streets. Here there is no disagreeable, perhaps I should say, delightful variety of mud, ankle-deep at one time, and hovering, but, alas! not golden, clouds of dust at another. On the contrary, there is a monotonous constancy of uniform, dry, and level pavement, where a lady might walk without soiling a white satin slipper. It is this monotony, I presume, that prejudices the public against such *galleries*, as they may very fairly be styled, more especially the one here under notice.

I say, "prejudices the public against them," because there is some reason to presume they have no attraction, or else by this time we should have many more erections of the same kind, if no where else, in those places at least that seem expressly intended for them, and unfit for anything else; for instance, the two squeezed-up alleys called the "Turnstiles," leading into Lincoln's-Inn fields; Middle-row, Holborn; Cranbourne-alley, and several others of the same description in Cornhill and its neighbourhood, all of them very greatly frequented thoroughfares, and more particularly disagreeable to pass through in wet weather. Were these widened, and covered in, and converted into galleries lined with the shops, they would, I think, be so many improvements; spots which one would be more inclined to visit than to avoid. It will, perhaps, be said that merely widening them would in many cases not be sufficient, some of these alleys being, if not absolutely crooked, full of windings and turnings. To which it may be replied, *tant mieux*, since, so far from presenting any obstacle, such deviations from an uninterrupted straight line would suggest many new ideas and combinations to an architect, that is, to an architect of any *nous* and taste. Indeed, much as I admire the Lowther Arcade, I by no means wish to behold any repetitions of the same subject, where there is so much scope for novelty and variety—far more, I will undertake to assert, than in almost any other class of buildings that can be mentioned. Styles that would be far too *outré* and fanciful for ordinary street architecture—decoration that can hardly be applied in exposed situations, might be employed here. Every variety of Gothic, from Norman to the latest Tudor—if I may be allowed to say so without getting a rap over the knuckles for apparently confounding Norman with Gothic—the Byzantine, Lombardic, Moorish, Italian, in all its most picturesque and peregrine fancies, or Pompeian, with its arabesque vagaries, or pure Greek, arrayed in all the pomp of its polychrome embellishment, might be resorted to at will. What displays of perspective might be obtained! what pictures! what painter-like effects! what magic witchery of light and shade! what—but this is raving—the very coinage and ecstacy of the brain. I am soaring on Pegasus—no, I have got astride on Astolfo's hippogriff, and have got nearly half way to the moon.

These harum-scarum flights do not do for sober company; my worthy progenitor, I am sure, never gave way to any thing of the kind. He never soared higher than a flying-fish, never frisked nor curvetted at all—at least, not more than a horse does in a mill. Therefore, let me endeavour to talk soberly; and, in sober seriousness, I would rather have a subject of this kind to work out according to my own i eas, than one of those grand affairs which seem to be of more mark and likelihood—at least, of far greater importance; yet which, after all, generally turn out to be very little better than common-place, magnified and displayed upon a more than common scale.

Highly satisfactory as the Lowther Arcade is in itself, it goes very little way towards showing what might be made of a gallery of this kind, by throwing greater play and variety into the plan, by increased loftiness in particular parts, by a sudden expansion in one place, and consequently the effect of contraction in another. A central rotunda, octagon, or hexagon, from which different vistas radiated, would even, were it in itself but of moderate size, give a piquant complexity to the design, and provide a point where some statue or other ornamental object would produce a striking effect. Though not exactly in the very best taste, the rotunda of the Passage Colbert, Paris, is a scenic, architectural bit, which shows what might be accomplished in that way. An upper aisle of shops on each side over those below might occasionally be adopted, and would certainly aid very much in varying the character of the particular design. In short, a place of this description is one that affords the utmost scope for invention, contrivance, and taste, and also for bringing together the features and characteristics of both external and internal architecture. There is hardly any kind of embellishment that might not be applied; and since the introduction of asphalt for that purpose, the very pavement might be made to assume a decorative character, and be variegated with ornamental patterns.

But how are such things to be done? Who is to pay for all this splendour? Taste is an exceedingly expensive and costly thing; such, at least, seems to be John Bull's opinion, although John is generally ready enough to suffer himself to be humbugged out of his money in paying double what he ought to do for many things that have no pretensions to taste at all. However, as I myself happen to have no taste whatever for the L. S. D. part of the business in such matters, I leave that consideration to other heads; merely remarking, that so far from there being any symptoms of lack of money among our shopkeepers to prevent their encouraging any architectural enterprise of the kind here mentioned, numbers of them seem to be contriving how to squander away as much as possible of that commodity, without any return to them for it in the shape of taste, for after all the extravagant expense they incur, they seldom, if ever, produce more than what is a little bedizened-out patch in a street or row of houses.

Perhaps I have been somewhat indiscreet—a rather blundering tactician in indulging my fancy as to what might be done, before I speak of what actually has been done. *N'importe:* the Lowther Arcade has sufficient merit of its own to satisfy as a very excellent specimen in itself: as a piece of design, it is in admirable keeping throughout; unostentatious, it is true, in its embellishments, but perfectly free from any alloy of that meanness which too frequently gives a strangely poverty-stricken air to buildings that, upon the whole, affect grandeur. Here nothing more appears to have been aimed at than what has been actually accomplished, which, as matters are generally managed, is certainly no little praise. There is none of that trumpery pomposity which may captivate the vulgar, yet disgusts the informed. And by vulgar I do not mean the vulgar in rank, but the vulgar in taste, let their rank be what it may. Neither are there any of those crude whims and whimsies that are occasionally palmed upon us as fancy and invention, I suppose, as for instance, that compound of heterogeneous absurdities and contradictions the front of the British Insurance-office. In the Lowther Arcade, on the contrary, the whole is made to appear perfectly of a piece, and the different parts so skilfully reconciled together, and harmonised one with the other, that what is Greek does not put us out of conceit with what is Italian, nor *vice versa*, does what is Italian shock us by the side of what is Greek. Without being in the least degree crowded, the whole design is well filled up. In regard to the mode in which this *passage* is covered over, I greatly question if there be in all the country a more beautiful ceiling vista than that here produced by the series of small pendentive domes, upon which the effect of the whole, as an architectural picture, so greatly depends. It is true, the sides consist merely of shops; but how much taste is shown in the design of the front contained within each compartment, more especially if compared with the insufferably dowdy office-windows, and those above them, that are thrust into the *grand* Ionic hall of the Post-office!—though, I suppose, it must still be allowed to pass as extremely classical, because it has no admixture whatever of Italian or any other style—save the genuine John Bull cockney. I have heard, upon what I consider very sufficient authority, that the designs for the Lowther Arcade were furnished by *a* Mr. Turner. Who the same Mr. Turner is, I know not, but I am sure he has no occasion to be ashamed of his name, at least not as far as this specimen of his talents is concerned with it.

CANDIDUS'S NOTE-BOOK.
FASCICULUS II.

"I must have liberty
Withal, as large a charter as the winds
To blow on whom I please."

I. Very few architects, I am sorry to say, appear at all to perceive the policy of diffusing a taste for, and some knowledge of, their art among the public. On the contrary, many have endeavoured, as far as in them lay, to deter non-professional persons from attempting to take it up as an agreeable study, by involving it in as much mystery as possible, and representing it as one that demands nothing less than a thorough acquaintance with the practical as well as the theoretical branch of it. This is not only decidedly foolish, but also untrue, and at variance with the common-sense course adopted in all analogous cases. You may allow a man to be an excellent judge of cookery, although you entertain so poor an opinion of his actual skill in it, that you would not trust him to dress a beef-steak. He may be a profound connoisseur in music, although unable to compose a single bar; a supreme authority in matters of painting, though he never put a palette upon his thumb; an oracle in matters of sculpture, though utterly ignorant of the processes of it; yet, if he ventures to meddle with architecture, to pretend to have an opinion of his own in regard to it, the chance is that he is scouted at once as a mere amateur, a conceited gentleman just capable of drawing out pretty-looking things on paper, and perhaps hardly capable of that. If, indeed, destitute of all practical knowledge, such a one assumes to himself the power of doing more, he very justly deserves to be treated as a shallow pretender, but surely not else. Did architects clearly see their own interests—I do not mean their own individual interest, because in many cases that may be best served by the greatest quantum of ignorance on the part of their employers, but the interest of their art—so far from discouraging amateurship, they would endeavour to render the whole public amateurs; because, unless there be something very peculiar and anomalous in regard to architecture, it should follow that the greater interest people in general take in it the greater relish they have for it, and the better they comprehend it, all the more likely are they to encourage it, and to encourage it with a proper feeling. As a body, therefore, the profession ought to do everything in their power to create and foster such taste; not only not to check it, but to encourage it with the utmost solicitude. At any rate, if they do not care to do so, they have no right to reproach the public with that ignorance, and consequent indifference in regard to architecture, which they themselves may be said to keep up, because they do nothing towards removing it. After all, of what are they afraid? Are they really apprehensive that the public would find out how very little talent, or original ability of any kind, is to be found in many buildings which, though they rank high as edifices, are entirely the work of the hands, not of the mind; in fact, do not require more, if even so much, contrivance and intelligence as is exhibited in many manufactures, which, nevertheless, are held to be purely mechanical?

II. Among those whimsical absurdities to which custom reconciles us is that of inscribing the name of the architect and the date of a building, not where they can be seen, and convey such information at a single glance, but where they must remain unseen for ever, namely, on the foundation-stone. Surely this practice must have been of Irish origin, since a more blundering one, and one more contrary to the plainest common-sense, can hardly be conceived. It is all very well to bury under ground the names of lord mayors, or other official worthies and dignitaries who *assist* at the ceremony of laying the first stone, because it matters not how soon they and everything relating to the childish *silver trowel part* of the business are forgotten; but that there should ever be any mystery, or room for doubt, as to who was really the architect of a building, when all uncertainty might be obviated by a mere name and date, is quite preposterous. Besides which, it is very likely to happen, and often does happen, that a structure is either rebuilt, or nearly, on its old foundations, and in such cases what becomes of the veracity of the inscription on the foundation-stone, should it ever come to light at all! Of this we have two notable instances in the Custom-house and the College of Surgeons, one of which has been, though only partially, altered so greatly for the worse from its original design, bad as that design was; and the other so metamorphosed from its original ugliness, as to be no longer the same buildings they first were. Had architects invariably made it the practice to affix their names to their works, we should now be at no loss to know who we are indebted to for those noble fabrics of olden time, which are the admiration of all. Why it should not be done I do not understand, when every engraver put his name to the plates he executes. Neither would there be any occasion that the architect's name should be ostentatiously displayed; for were it cut merely on the lintel or architrave of a door, the plat-band above a basement, or some member of that kind, it would not obtrude itself on the eye, nor discover itself till sought for.

III. It looks somewhat like inconsistency, that at the very time they wish architecture should be ranked as one of the fine arts, professional men should lay so much stress as they do, not merely upon the practical but upon the mere business-like part of it. Should you happen to express your surprise that Mr. Such-a-one obtains so much employment, when he has on no single occasion shown any talent, perhaps the reply will be, "Oh, but he is a most excellent man of business;" the plain English of which is, that let architects fancy themselves what they may, the public consider them in no other light than tradesmen; and in nine cases out of ten the public may be perfectly right. By no means do I assert that talent never finds employment, but it will, I believe, generally be found that it is the very last thing that recommends a man to it.

IV. That the Elizabethan style possesses historical interest I do not dispute, but that it offers any beauties or advantages to recommend it as a mode of architecture is what I must be allowed most flatly to deny. Its only principle is the disregard of all architectural principles, and of all artistic feeling. Very seldom do we meet with anything in it that can be termed really good, even estimated according to what may considered the leading taste of the examples themselves; or if there happen to be some particular feature that satisfies the eye, it is a mere solitary bit in the composition—although it is rather an abuse of term so to employ it—without anything to harmonise with it. Besides which, notwithstanding their licentiousness of design, the examples of this style betray great dearth of ideas and poverty of imagination; for, be it observed, there is a most wide difference between whimsies and fancies and fancy itself. I have met with some people who, in aiming at being amusingly lively, have only been impertinently frisky: nor is it a small degree of awkward friskiness that characterises the style in question, and causes it to appear even more dull than it else might. It is no more than right that we should know what it really was; but its examples ought to be held *in terrorem*, certainly not for imitation, except it be that species of imitation which enables an artist to appropriate what is available for better purposes, rejecting all the dross. Yet those who have of late served up this style to us have generally taken care to give us garbage and all. Certainly no one has hitherto attempted to discriminate between its best and worst qualities, or to point out what it offers for adaptation to our present purposes; since, leaving taste entirely out of the question, it has nothing whatever to recommend it as a mode of building adapted to our present habits and tastes; certainly nothing on the score of comfort and convenience, on that of economy perhaps even less, since it is only lavish profusion of decoration that can conceal its native ugliness. I may be told that it is a truly national style, that of our ancestors: national nonsense! So were trunk-hose and cumbersome ruffs at one time our national dress, yet what man—I do not say of sense, but in his senses—would wear them now, unless determined to establish for himself, at all hazards, a character for singularity? We do nothing else like our ancestors; then why, in the name of common sense, should we put ourselves into their most grotesque and unseemly architectural fashions? I have been led to these remarks by looking over the first number of Richardson's "Architectural Remains;" which work professes to give only the choicest specimens of the Elizabethan period; and is therefore likely to effect good, by exposing the unmitigated deformity that prevails even in what we must presume to be comparatively pure in taste, and happy in invention. It is a pity Mr. Richardson, who, of course, thinks very highly of John Thorpe's architectural taste, should not think sufficiently well of John Britton's literary taste as to take that learned sexagenarian's dedication to the queen as a model for his own. In regard, however, to the style—I do not mean of sexagenarian's dedications, but of Elizabethan architecture—I conceive it would be a far nobler object of ambition in the profession to aim at forming what might hereafter be distinguished as the *Victorian*, than to content themselves with aping what is called the Elizabethan.

V. Gwynn's "London and Westminster Improved" is pretty well known to every one by name, but it is not, perhaps, so generally known that that writer is apt to be occasionally rather satiric. The following remarks, for instance, are somewhat in the spirit of Boz. "The powers of inventive genius are at this time so very little attended to, and the examples of Greece and Rome so firmly established, that nothing more is required to model a youth of moderate parts into a complete architect, than to put him apprentice to a bricklayer, mason, or carpenter, under whose tuition he will acquire the great art of scoring straight lines, and setting off their proportions by scale and compasses. His servitude being ended, thus accomplished and furnished with the rudiments of architecture, he may be sent to Rome, and after he has spent the usual time for traversing that city, he may cause it to be inserted in the London papers, that Mr. Trowel, the *celebrated architect*, on account of his vast abilities, has had prodigious honours conferred upon him, and that he shortly intends to revisit his native country, to which he will no doubt do infinite honour." This, it must be allowed, is tolerably *Bozzish*, and convinces us that quackery was understood before our own time. "But to be serious," he continues, "where is the necessity for this parade of going to Rome? Is there a building, or even a fragment of a building in Greece, or Italy, of which we have not accurate draughts and measures? and is it not from these resources that *every modern building is compiled*, without variation, and without the least attempt at novelty or invention? It is very much to be questioned, if such an attempt was to be made, whether a thorough-bred connoisseur would vouchsafe to bestow a second look upon such a design." That Gwynn must have been a brave fellow! And yet, he might as well have "whistled to the winds," as attempt to correct the inveterate pedantry of "thorough-bred connoisseurs," and the servile commonplace routine of architects. What inconceivable magnitude of talent it must require to be able to follow a pattern, and make an exact copy of columns, and things of that sort! Is not that exactly your opinion "My Public"? Aye, to be sure it is.

PLAN FOR A HARBOUR AT HASTINGS.

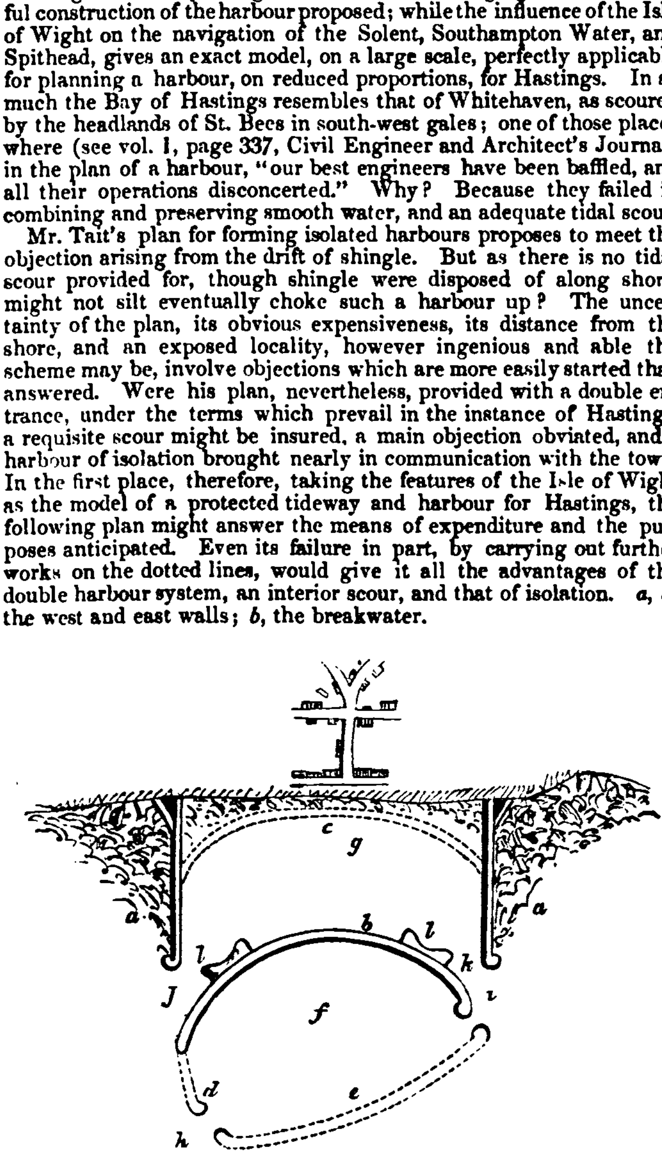
BY A SERIES OF PROGRESSIVE IMPROVEMENTS.

By John Rooke, Esq., Author of "Geology as a Science," &c. &c. Applied to Engineering.

The plan of a harbour for Hastings, noticed in "The Civil Engineer and Architect's Journal," vol. 1, page 338, being closely associated with the course of the tides in the British Channel, so must the tideway be first considered; as upon the influence of these tides, and the projections of land upon the line of shore, depends the success or failure of artificial works for the shelter of sea vessels. To the deeps of the Atlantic Ocean, the origin of tides in the British Channel may be distinctly traced; the line of tidal current is, therefore, from the westward, terminating in the strait of Dover, and there meeting the opposing balance of a tidewave from the North Sea. In the western section of the British Channel, the force of flood tides propelled eastward by a powerful pressure from the Atlantic Ocean, as a result of fluid action, drives beds of shingle forwards, which are necessarily deposited in the eastern section thereof, since the force of the reflux tides is less than that of the flux tides. As Hastings is situated in the eastern section of the British Channel, and not far distant from the terminus of a tidewave, which has a general course parallel to the trending of the shore, so shingle has a decided tendency to drive eastward, and convert harbours lying in its course into what have been designated "shingle traps." The cause of this result is plain. If the North Irish Channel, where the tidewave is continuous, be compared to the eastern section of the British Channel, where the tidewave terminates, we observe a marked difference. In the one, drift is propelled onwards, and deep water preserved, because a continuous scour prevails; while, in the other case, the scour terminates, and the drift is deposited. It is by observing these results, that in planning a harbour for Hastings, we ascertain the general laws by which the engineer must be guided.

We may now restrict our observations to the localities of the English coast, along the British Channel, and, passing from Land's End up to the Isle of Portland, we see that the Chesil Bank is the first decided accumulation of drifted shingle. The projection of this isle, however, forcing the tidewave southward, causes it to run northward, again, with great force, and scour out the Bay of Weymouth. We next observe the Isle of Wight taking the position and form of a geological deposit, projected from the headlands of St. Alban's and Durlestone; and opposite the great fresh-water drain of Southampton Water. In Swanage, Studland, Tollande, and Colwell Bays; and in the Solent, Southampton Water, and Spithead, a deflection of the tideway on shore, and, according to an angle of incidence, operating in conjunction with the Isle of Wight, has preserved deep water, and a continuous navigation. Between Selsey Bill and Beechey Head, we observe another of those undulations seaward, and deflections on the line of shore again, which have more or less preserved continuously deep water. Beechey Head having driven the tideway southward, necessarily causes it to run on shore again, according to the angle of incidence on which it has been pressed seaward, whence we are able to assign a distinct cause for the prevalence of permanently deep water in Pevensey Bay, and up to Hastings. This may be regarded as so far encouraging for the successful construction of the harbour proposed; while the influence of the Isle of Wight on the navigation of the Solent, Southampton Water, and Spithead, gives an exact model, on a large scale, perfectly applicable for planning a harbour, on reduced proportions, for Hastings. In so much the Bay of Hastings resembles that of Whitehaven, as scoured by the headlands of St. Bees in south-west gales; one of those places where (see vol. I, page 337, Civil Engineer and Architect's Journal) in the plan of a harbour, "our best engineers have been baffled, and all their operations disconcerted." Why? Because they failed in combining and preserving smooth water, and an adequate tidal scour.

Mr. Tait's plan for forming isolated harbours proposes to meet the objection arising from the drift of shingle. But as there is no tidal scour provided for, though shingle were disposed of along shore, might not silt eventually choke such a harbour up? The uncertainty of the plan, its obvious expensiveness, its distance from the shore, and an exposed locality, however ingenious and able the scheme may be, involve objections which are more easily started than answered. Were his plan, nevertheless, provided with a double entrance, under the terms which prevail in the instance of Hastings, a requisite scour might be insured, a main objection obviated, and a harbour of isolation brought nearly in communication with the town. In the first place, therefore, taking the features of the Isle of Wight as the model of a protected tideway and harbour for Hastings, the following plan might answer the means of expenditure and the purposes anticipated. Even its failure in part, by carrying out further works on the dotted lines, would give it all the advantages of the double harbour system, an interior scour, and that of isolation. *a, a,* the west and east walls; *b,* the breakwater.



In the foregoing outline, it is proposed that each succeeding step of the plan shall be determined or varied according to the practical results previously shown. In the first place, the breakwater *b* would be constructed when a scour would commence, of which the extent and direction should be closely watched. Next the west and east walls might be commenced and carried out according to the operations exhibited by the progress of the work. These finished, the interior scour of the harbour, if insufficient, would suggest the extension of the breakwater still further along the dotted line *d*, until the scour within the harbour should be sufficiently powerful, by which the plan of the harbour would bear a resemblance to the Isle of Wight pressing upon the waters of Southampton, the Solent, and Spithead. The scour thus established would then determine the position and figure of a quay on the side of the dotted line *c*; and if these various works, when combined as a whole, should fail in affording a harbour of refuge, then the dotted line, *e*, might be built in addition, and thus give an inner harbour, *g*, and an outer harbour, *f*, or partly an isolated harbour. Thus vessels taking refuge in the one, could be subsequently towed into the other by a steam-tug, if required; and docks might then be added as a security and convenience to the whole. On the plan here detailed, the entire works would be determined by practical results, errors would be corrected, and no step in the process need be regretted or retraced.

What has been here sketched out must, however, be considered merely as a free outline, subject to remodification in its details, rather than as an absolute or invariable plan. The convexity of the curved line, *b*, is intended to scour and preserve deep water along the line of the concave curve opposite thereto, marked *c*; and if the run of water along these curved walls were too powerful, such defect might be mitigated by adding undulating jetties at the dotted points, *l, l*. Ever keeping experimental results in view, the spaces of the entrances, *j* and *k*, and those of *h* and *i*, if called for, might be in some measure determined by such a rule.

Though the harbour, *g*, might appear somewhat exposed to either eastern or western gales of wind, from having double entrances, yet the smoothness of regulated water flowing in continuous lines obviates its rebound, and more than compensates the security which a single entrance affords. The breadth of water within the harbour, *g*, exceeding the space of the entrances, *j* and *k*, smooth water and an accumulation of silt would be a more likely objection than the excessive force of a passing and onward current. A material advantage in disposing the lines of walls in curves and diagonally, in place of at right angles to the course of the tideway, would be that of smoothing the water, easing the various works, cheapening their construction, and augmenting their security, besides directing the force of the tidewave on those points mainly where a scour might be desirable, and giving the greatest depth of water along the proposed line of wharf.

SCHOOL OF CIVIL AND PRACTICAL ENGINEERING,

AT THE SCOTCH NAVAL AND MILITARY ACADEMY, EDINBURGH.

We had prepared last month an account of the Engineering School at Edinburgh; but the pressure of other matter compelled its delay. We are now, however, by the kindness of T. Compton, Esq. (formerly of Woolwich), the Professor of Civil Engineering in the Academy, enabled to give a better description than would otherwise have been in our power. The class of civil engineering has been in activity since November, 1835, and consists of the departments of mapping and plan-drawing, construction, practical surveying, and administration, or the mode of making out specifications and estimates. The class is actively employed in summer in surveying the most interesting localities in the neighbourhood of Edinburgh; and its success under its able conductor has been such as to lead the directors to form a class for practical engineers. This is to be divided into the sections of drawing, pattern-making, moulding, and casting; millwright-work, theory and construction of steam-engines, miscellaneous machinery, boiler-making, and locomotive machinery. The course of instruction in this latter department is intended to be three or four years; and the terms thirty-two guineas the first year, twenty-four guineas the second, twelve guineas the third; and, if a fourth, six guineas; the fees payable quarterly, in advance. These terms are high; but, altogether, the institution, proceeding on a practical basis, is calculated to effect much good. We should wish, however, that it was in the power of the directors to place the institution within the reach of mechanics; as, with great liberality, they have thrown the school open to amateurs at three guineas per quarter. We think that it is well worthy of the attention of the directors to make instruction in the steam-engine a part of the course of their naval pupils, and also to afford facilities for the instruction of steam-boat engineers, which would be a more efficient measure for preventing accidents, than any quack laws and jobbing superintendents.

OBSERVATIONS ON THE IRISH RAILWAY COMMISSIONERS' REPORT.

With no unfriendly feeling either to the Irish Railway Commissioners, or to those professionally connected with them, we again make further observations on the Irish Railway Report, as a public document executed at the expense of the people.

Does not the following suggested distribution of railroads through Ireland exhibit a spirit of favouritism and partiality, when, for the southern division of Ireland, the Railway Commissioners have laid out 359 miles of railway, estimate 5,317,884*l*., and for the northern 152 miles, estimate 2,336,258*l*.; while no railway has been laid out for the centre of Ireland, nor for the whole province of Connaught?

In the September number of this Journal we took a general view of the Report; we showed that the general system of railways laid out through Ireland by the Commissioners was wrong; we also showed in correct detail numerous errors, both in the maps, plans, sections, and gradients, such as were sufficient not only to destroy the reputation of the work, as to its accuracy, but even affecting the very characters of the individuals who had incautiously compiled and published so erroneous a document. Those numerous and serious errors were laid before the public through the columns of our Journal six months ago, and have not been questioned or replied to in any published works to our knowledge, by any of the commissioners or their friends, no, nor even by the grandson of Charles Hutton, nor the *eleve* of Telford, deeply and seriously as it affects both of them, the Railway Commissioners, and even the Government, after an expenditure of nearly twenty thousand pounds, and a loss of more than two years' time.

We ask, what will the engineers of France and of America say in examining such an inaccurate production? Will they not justly exclaim, Behold, the people in the country of Newton, of Napier, and Maclaurin, are now so reduced in scientific acquirement, that they are not able to work accurately the simple operations of decimal arithmetic? Is it not humiliating to think that among the rulers of this great empire that so few individuals of scientific acquirement are to be found? Sir Davies Gilbert and Lord Oxmantown are men of science; the former has now nearly reached the maximum age allotted to man, while we regret that political influence has swept the latter from that position in the councils of the sovereign and the country which his talents and acquirements so pre-eminently entitled him to occupy, for to aid the advancement and the progress of those interests connected with the works of science and improvement, which so few could comprehend and understand so well among the representatives of the country. We are happy to have an opportunity of testifying our great regard and esteem for Lord Oxmantown, not only as a cultivator of science in its highest branches, but also of his devotion to the prosecution of practical mechanics. Has not one of the most distinguished *savans* of the empire declared—" That the sciences and the arts of England are in a wretched state of depression, and that their decline is mainly owing to the ignorance and supineness of the Government, to the injudicious organization of our scientific boards and institutions, to the indirect persecution of scientific and literary men, by their exclusion from all the honors of the state." And has it not been truly said that—" The young diplomacy of the American States was raised into distinction when Franklin took upon himself the functions of her ambassador, and France was at the zenith of her glory when the Marquis La Place was President of her Conservative Senate, Lagrange a Peer of France, and Carnot her Minister of War."

A few leading articles have appeared from time to time in the ministerial papers, praising the Irish Railway Report, but the acquirements of the editors of newspapers are such as to exclude them from being able to review such a work, and to those who understand such subjects, those leading articles must appear to have been put forward by the commissioners and their friends, to support their very objectionable system of Irish railway projects. It is remarkable that the government of the country found it necessary to employ a gentleman to travel through Ireland for the express purpose of praising this railway report, at various public meetings which had been held in that country —and this was actually acknowledged publicly by the individual so employed.

The " Quarterly Review" for January, 1839, contains an article on the Report of the Irish Railway Commissioners; but it contains nothing that had not been previously published or well known before, and it is only remarkable for introducing a vast variety of subjects totally irrelevant to the one it professes to discuss. We beg to observe, that Mr. David Stevenson never was at New Orleans, and that the information regarding the steamers at New Orleans, which the " Quarterly Review" quotes at page 6, is from the pen of Captain Basil Hall, who had visited New Orleans, and not from that of Mr. Stevenson, who had not been there; the statement of the " Quarterly" is, therefore, not correct. The observations made on the democratic institutions of the North American Republic at page 25, are not only quite unworthy of the intelligence of the age, but they are, in our opinion, unfounded and untrue. The property of the people of the United States of America is just as secure as that of the people of any other country. The laws which govern the free and independent states of the North American Republic are more likely to spread through the great American continent than those of the arbitrary and despotic governments of Europe; in all likelihood those principles of freedom which have been spreading so widely for the last 50 years, will yet be extended much more, and ameliorate the condition of the human race in the most remote and distant regions of the earth. Matters of a political kind we do not profess to discuss, and we regret to do so in any manner; but our excuse is, that for the American people of the United States we entertain the highest respect, and we therefore do not like to see them and their institutions calumniated in pages which profess and avow to be consecrated to the discussion of a scientific subject, and which our avocations oblige us to notice, and more particularly as an attempt will be made to convert the Irish railway monopoly into a political state job; it therefore becomes a sacred duty with us to expose it to the fullest public animadversion.

" We conceive the principal question in this inquiry to be—Does the report emanate from persons possessing, in the opinion of Europe, the requisite qualifications? We have, accordingly, taken some pains to inform ourselves upon this subject."—Quarterly Review, December, 1838.

The account given by the " Quarterly Review" on this very important matter, has established, in the clearest manner possible, that none of the Irish Railway Commissioners had ever executed any kind of railway works; and it therefore cannot fail to appear to those possessed of practical knowledge in railway engineering, that the nomination of such a railway board was a very extraordinary proceeding on the part of the executive; to depute such men to legislate on matters they never had been previously acquainted with, was certainly, to say the least of it, not an arrangement either consonant to reason, nor creditable to the wisdom of the government of this country. When the legislature had deemed such a commission necessary to lay out a system of railways for Ireland, why were not individuals of the highest practical skill in railway engineering, totally unconnected with Ireland, selected for such a purpose? And this service, we affirm, could have been accomplished in four months, and the reports, sections, plans, &c., might have been with ease delivered in less than eight months, while these Railway Commissioners required nearly two years, involving in its consequences a loss of *three years to Ireland* in the progress and extension of railways, inflicting a deep and lasting injury upon her prosperity, and the unemployed population of that country.

We are advocates that great works of national utility should originate with the people—we are inimical, in the highest degree, to legislative interference with anything, from the making of a steam-engine to that of the smallest article; we conceive it is the duty of a wise and a paternal Government to aid and assist public companies in their exertions and endeavours to execute works of public utility: but, on the other hand, if a Government once assumes the mantle of general manufacturer of steam-engines, engineer-general of railroads, &c., under an act of the legislature, then the rights and interests of all the industrious classes are directly invaded, a monopoly set up, and the spirit of enterprise, of invention, and improvement ceases, and all those vigorous trading impulses which have so eminently contributed to the wealth and to the prosperity of all free and enlightened countries, but particularly the great advantages which would result to Ireland by the introduction of English capitalists. We deny the right of the British Government to step in at the eleventh hour and interfere, except so far as the public interests may require, with either the English railway companies, or even those of Ireland, which have been formed, by men who have, in England, Scotland, and Ireland, congregated together, subscribed and risked capital, called into existence a new power, executed the most stupendous works with the most triumphant success, and all without the aid of a Royal commission. Will not the Government of this country read a lesson of wisdom from past events? Has not steam navigation across the Atlantic Ocean been achieved in the most satisfactory manner by private enterprise? Have not the river navigations, and also the whole of the canals of England, been executed by companies? Are not all the steam-vessels which cover, not only the British seas, but also those of Europe, entirely due to the successful enterprise of companies? And have not the noblest engineering works in the world been accomplished by private companies? Look at the bridges of Waterloo and Southwark; they will prove that the people are quite capable of executing works as stupendous and monumental as the pyramids of Egypt, but of a much more useful and noble kind. We are thoroughly convinced that wherever works of a public nature have been executed by the Government, they have not only been inferior to those now named, but they have also been attended with much more expense than if undertaken by private enterprise. If we look at the imperfect execution, *and unfinished state*, of the Caledonian Canal, after an expenditure of one million sterling, and thirty-five years of time, it is really not calculated to inspire people with confidence in the executive of the country, as either being the best or most competent authority to execute public works. Or, again, at the suspension-bridge erected over the straits of the Menai, a structure strongly characterised by its inferiority of strength and durability, as compared to those bridge-works erected either in ancient or modern times. This fragile and perishable work was constructed under Royal authority, and which the passing breeze not only dismantles and renders impassable, but is also fast consuming its strength by the vibratory motions to which it is constantly exposed, as well as the never-ceasing oxidation of the material which forms the main and imposing feature of that structure. The expense of the Holyhead-road and bridges is stated in the appendix, p. 366, of Sir Henry Parnell's book on roads, at £759,710. 6s. 11d. sterling, and the expense of the execution per mile of the road is from £4,000 to £5,000 sterling, and the tolls upon that road are much higher than upon any other road in England. We are not aware that Government toll-roads or Government steam-boats are cheaper to travel on, and voyage in, than those of private companies. For example, the fare from Dublin to Liverpool, in her Majesty's steam-vessels, is from five to ten shillings more than what is charged by the Dublin Company's steamers from the quays of Dublin; so much for Government cheapness.

It is not only painful to contemplate the odious monopoly of government in the post-office department, but it is really extremely injurious to this great commercial country that the postage of letters should be overwhelmed with so high a rate of duty. What insanity then to talk of the government of this country becoming constructors of railroads and carriers of passengers. "Legislation is not health but human welfare;" and the government of Great Britain has quite enough to do in legislating for this great empire and the colonies thereunto belonging, without interfering with projects which should be left entirely to the enterprise of the people under proper legislative restrictions for the good of the public.

Looking at France, one of the most powerful nations in Europe, and where by arbitrary authority the public works of that country had been placed under the controul of the state; are those works, we ask, more substantially executed, or kept in a better state of repair than those of Great Britain? Is it not allowed by every person who has travelled through England and France, that the roads of the former country are much better than those of the latter, and that the superiority in the velocity of travelling in Great Britain is well known and admitted to surpass that of any other country. It is also remarkable that our bridges, docks, harbours, canals, aye and also our railways, are, we venture to lay with pride, the most substantially executed, and the grandest works of the kind that the people of any nation in the world has yet executed. These noble engineering works astonish all travellers who have visited Great Britain; they announce the genius and enterprise of not only a great, but that of a free people, whose unparalleled activity and intelligence have not been fettered and withered by legislative enactments in the promotion of commerce, the increase of our national wealth, and the consequent greatness of this empire: and this may be justly attributed to perfect freedom being allowed to every kind of private enterprise under parliamentary regulation.

Let us examine how far the Railway Commissioners have been able to lay out a judicious system of railroads for the southern division of Ireland, and whether they have been able to do so upon better levels, and at a less expenditure of mileage than private companies.

First, to connect the cities of Dublin, Kilkenny, and Limerick, the following will show the extent of mileage and the gradients.

Length of mileage by the Railway Commissioners' lines.	M.	F.	Length of mileage by the Companies' lines.	M.	F.
Dublin to, Limerick chateristic gradient 1/180	128	4	Dublin to Limerick, chateristic gradient 1/330	111	0
Branch to Kilkenny, chateristic gradient 1/300	26	4	Branch to Kilkenny 1/600	28	0
	155	0		139	0
			Difference in favour of the Companies' lines	16	0

Hence it appears by these facts that the system of railways proposed by the Companies to connect Dublin, Kilkenny, and Limerick, would be sixteen miles shorter than the length of those railways proposed and recommended by the Railway Commissioners.

Again, taking Dublin, Kilkenny, Limerick, and Cork, and comparing the number of miles of Railways which will be required to connect them, first, by the system proposed by the Railway Commissioners, and secondly, by the Companies' system.

By the Railway Commissioners' system.	M.	F.	By the Companies' system.	M.	F.
Dublin to Limerick	128	4	Dublin to Limerick	111	0
Kilkenny branch	26	4	Kilkenny branch	28	0
Cork branch	76	7	Cork branch	68	4
Small Southern branch at Donahill	13	0			
	244	4		207	4
			Difference in favour of the Companies' lines	37	3

Here again, in comparing the Companies' lines of proposed railways with those laid out by the Railway Commissioners, there would be a saving of 37 miles 3 furlongs by adopting the Companies' system, which is very serious, viewed both as to the first expense of construction, and afterwards in working those lines of railroads.

We shall now exhibit the distances to be travelled in going from Dublin by Limerick to Cork, from Dublin to Kilkenny, and from Limerick to Cork, &c., by the Commissioners' lines and also by those proposed by the Companies.

By the Railway Commissioners' lines	M.	F.	By the Companies' lines	M.	F.	Diff. in favour of Companies' lines. M.	F.
Dublin to Limerick	128	4	Dublin to Limerick	111	0	17	4
Limerick to Cork	98	2⅓	Limerick to Cork	68	4	29	6⅓
Dublin to Kilkenny	82	0	Dublin to Kilkenny	75	0	7	0
Dublin to Limerick & Cork	226	6⅓	Dublin to Limerick and Cork	179	4	47	2⅓
Dublin to Waterford	144	2	Dublin to Waterford	103	0	41	2

The direct distance from Dublin to Cork by the Commissioners' line not passing through Limerick, would be 169 miles 5 furlongs; by the Company's line, passing through Limerick to Cork, would be 179 miles 4 furlongs; difference in favour of the Commissioners' line 9 miles 7 furlongs. Looking attentively at the above table, and also at the map of Ireland, it will appear that the Companies' lines possess many and great advantages over the Railway Commissioners' system of railways as laid out in the south of Ireland.

It appears by the Railway Commissioners' maps that a railway has been delineated on the map from Clonmel to Waterford, but in examining the estimates, it does not appear that any item of expense is to be found for constructing the continuation of the railroad from Clonmel to Waterford, distance 26½ miles, which, at 10,000*l.* per mile, would be 262,500*l.*, which is a serious error committed by the Railway Commissioners; for it is not possible to think that they ever thought of excluding the city of Waterford from the benefit of railway communication. In the Railway Report, appendix A, No. 1, page 11, it is there stated that no survey was made of the Limerick and Waterford line for the Commissioners further than Clonmel. This is certainly an extraordinary admission as regards the city of Waterford, containing 30,000 inhabitants, having an excellent port, an immense shipping of both sailing and steam vessels, and an export trade of more than two millions sterling.

In looking over the Railway Report we find it stated at page 41, that the distance from

Dublin	to Cork	is 166	miles	5	furlongs
...	to Limerick	125		4	
...	to Waterford	141		2	
...	to Kilkenny	79		0	

These distances are all incorrect, for in looking over the sections, the zero of mileage is placed *three miles* from the Dublin Post Office; and therefore three miles should be added to each of the above distances; for example Cork is 169 miles 5 furlongs from Dublin according to the figured sections given by the Railway Commissioners, and not 166 miles 5 furlongs, &c., &c.

At pages 104 and 105 of the Irish Railway Report, the powers of four locomotive engines are given. The diameter of the cylinders, the length of stroke of the pistons, diameter of the wheels, and the weight of the engines and tenders have also been stated.

"Now the whole power of these several engines is found by multiplying the area of their respective pistons by the pressure (64.7lbs.,) and then reducing this product to the circumference of the wheel."

"In this way it will be found that the whole power is:—Class first.

3755lbs.; class second, 2488lbs.; class third, 2337lbs.; class fourth, 2090lbs."

We have examined those calculations but have not found one of them correct.

CLASS 1.

$3{\cdot}1416 \times 54 = 169.64$, circumference of wheel,

$14^2 \times {\cdot}7854 \times 2 = 307{\cdot}876$, area of 2 pistons,

$2 \times 16 = 32$ inches, length of double stroke,

$307{\cdot}876 \times 64{\cdot}7 = 19919{\cdot}62896$, force applied on the pistons,

$\frac{169{\cdot}64}{32} = 5{\cdot}301$, ratio of the velocity of wheel and piston,

$\frac{19919{\cdot}62896}{5{\cdot}301} = 3757{\cdot}71$lbs. power applied to make the engine advance.

CLASS 2.

$12^2 \times {\cdot}7854 \times 2 = 226{\cdot}195$, area of 2 pistons,

$226{\cdot}195 \times 64{\cdot}7 = 14634{\cdot}816$, force applied on the pistons,

$\frac{3{\cdot}1416 \times 60}{2 \times 16} = 5{\cdot}890$, ratio of the velocity of the wheel and piston,

$\frac{14634{\cdot}816}{5{\cdot}890} = 2484$lbs. power applied to make the engine advance.

CLASS 3.

$11^2 \times {\cdot}7854 \times 2 = 190{\cdot}0668$, area of 2 pistons,

$190{\cdot}0668 \times 64{\cdot}7 = 12297{\cdot}32196$, force applied on the pistons,

$\frac{3{\cdot}1416 \times 60}{2 \times 18} = 5{\cdot}236$, ratio of the velocity of wheel and piston,

$\frac{12297{\cdot}32196}{5{\cdot}236} = 2348$lbs. power applied to make the engine advance

CLASS 4.

$11^2 \times {\cdot}7854 \times 2 = 190{\cdot}0668$, area of 2 pistons,

$190{\cdot}0668 \times 64{\cdot}7 = 12297{\cdot}32196$, force applied on the pistons,

$\frac{3{\cdot}1416 \times 60}{2 \times 16} = 5{\cdot}890$, ratio of the velocity of wheel and piston,

$\frac{12297{\cdot}32196}{5{\cdot}890} = 2087$lbs. power applied to make the engine advance.

"The gradients also, on the regulation of which so much depends, both in respect to the original cost and the ultimate value of the railway to the country, have been carefully gone over by one of the commissioners, in conjunction with the engineer, and in consequence several material alterations were made, which have much lessened the amount of the original estimate, without affecting; in an important manner, either the rapidity of intercourse or the commercial advantage." —Page 37, Railway Report.

In the September number of our journal for 1838, we printed a list of sixty-five errors found in the gradients, and upon a more full examination there will be found at least from forty to sixty more; this clearly shows that very little care or attention was bestowed by the commissioner and engineer who had examined and gone over the gradients; indeed, the very numerous errors found in the gradients are destructive to the character and accuracy of the Railway Report and Sections, although

"My Lords had full confidence, from the character of the gentlemen appointed to form the commission, that their inquiries would be conducted in a satisfactory manner."

We consider an alteration in gradients from one in 330, to one in 180, as most important, both as to rapidity of intercourse, and also as to commercial advantage, although the railway commissioners do not think so.

The same force of traction which is required to draw 100 tons up a rise of one in 330, would draw on the level 195 tons.

	tons.		lbs.		lbs.
	100	×	8	=	800
			$\frac{100 \times 2240}{330}$	=	679
Engine			$\frac{12 \times 2240}{330}$	=	81
					1560 Total resistance not including the friction of the engine.

$\left(\frac{1560}{8} = 195 \text{ tons.}\right)$

The same force of traction which is required to draw 100 tons up a rise of one in 180 would draw on the level 274 tons.

	LBS.
100×8lbs. $= 800$lbs. friction at 8lbs. per ton.	800
$\frac{100 \times 2240}{180} = 1244$lbs. gravity of the 100 tons (reduced to lbs.) on a plane inclined in the ratio of $\frac{1}{180}$	1244
$\frac{122 \times 2240}{180} = 149$lbs. gravity of the engine on the same plane	149
Total resistance not including the friction of the engine	2193

$\left(\frac{2193}{8} = 274 \text{ tons.}\right)$

This shows the difference between the rise of one in 330 and one in 180.

The load, tender, and engine, taken at 100 tons, and running at the rate of 20 miles per hour on the level plane, will, on ascending a slope of one in 330, run only at a rate of 14.20 miles per hour, and ascending a slope of one in 180, will run at a rate of 11·43 miles per hour.

An engine capable of evaporating 48 cubic feet of water per hour wil draw on the level plane 88·32 tons, at the rate of 20 miles per hour

up, 1 in	500 —	51·96 tons,	......
...	400 —	46·49 tons,	......
...	300 —	39·09 tons,	......
...	200 —	28·44 tons,	......
...	100 —	11·97 tons.	......

Woods on Railways. Page 578.

Looking at the levels which the surface of Ireland presents, we differ entirely with the Irish Railway Commissioners, as to adopting 1 in 180 as the characteristic gradient for the main trunk lines proposed to be laid out through that country; and we object still more so to 1 in a 100 for the great main line of railway laid out from Dublin to Cork, which appears by the Railway Commissioners' sections to be the characteristic gradient of that line, because an engine running up such a slope can only draw about one-eighth of the load that it can on the level plane; and running up 1 in 180 less than one third of the load it can draw on the horizontal plane. We are, therefore, thoroughly convinced that the Irish Railway Commissioners have not sufficiently studied this most important element in railway engineering; or has their limited knowledge of such a subject precluded them from being able to comprehend the vital advantages arising from the adoption of good gradients, even although attended with some expense in cutting and embanking?

In our journal for last September, we forcibly alluded to the very great injustice of not giving railway communication to the centre of Ireland, and also to the fertile province of Connaught; we stated our reasons why that province ought to participate in railway intercommunication, as well as the other provinces of Ireland. In the same number of the journal we stated our reasons fully against the line of railway projected by the commissioners from Dublin to Armagh, and we particularly observed that it ran parallel with the coast railway for nearly one hundred miles, and that it could not be possible that two such lines could exist, as one or other of tnem would be a total failure. Having with some attention sudied the commissioners' inland lines of railway from Dublin to Armagh and Enniskillen, we think that those projects recommended by them are extremely injudiciously planned; because, if an inland main trunk line was to be laid out from Dublin to Armagh, with a branch line to Enniskillen, and were it determined upon that the important trading town of Drogheda should be exclnded from railway communication with the capital, then lines of railway might have been chosen which would have united Dublin to Armagh and Enniskillen, with a saving of twenty-six miles of railway, which would be a great advantage as regards economy, not only in the first construction of these lines, but also in the working of them afterwards.

The system of main lines of railway, which have been proposed to be carried into effect by the various companies through the south of Ireland, possess superior advantages in connecting the various large cities together, than those recommended by the Irish Railway Commissioners. The lines proposed by the companies being much more expensive, and laying open a wider, a more populous, and a richer extent of Ireland's surface, with less mileage and better levels than the Irish railway commissioners' main lines appear to do. This fact has been established by the calculations already given; and by examining the Irish commissioners' index map of the proposed railways, there is to be seen a small triangular portion of country lying between Cahir and Hollycross which is completely encompassed by railways, amounting to more than 40 miles in length, and which cannot fail to strike every engineer, who will take the trouble to examine the proposed system of Irish railways laid out by the commissioners, to be an extremely defective and objectionable one, as to the distribution of this intercommunication by railways through the southern division of Ireland, as far as regards the connecting of the cities of Dublin, Kilkenny, Limerick, and Cork; although the royal commissioners had before them a very sensible and also an ably written paper by a gentleman of the name of Sinclair, who seems to have studied the subject of railways with deep attention. He states in his letter addressed to Peter Barlow, printed in the Railway Report Appendix, A. No. 12, page 83, in which the following paragraph is to be found:—

"In laying out great or general lines of railway through a country, my experience of the system generally leads me to think, that it would be extremely desirable to carry such main lines so near to considerable towns as to *supersede the necessity of branches.*"

Let us hear what the royal commissioners say on this subject:— "It is not by selecting a line to some large town, and conferring upon it the imposing title of a grand trunk line, that the object for which we are contending is to be accomplished." Then, was it wrong to have connected Liverpool, Birmingham, and London together by one main line? Was it wrong to have connected Bristol and London by one direct main line, and titled it the Great Western? Nothing, in our opinion, is better than to have large cities at the termini of railways.

The system of railways which have been proposed in the south of Ireland by the Irish Railway Commissioners, has evidently been copied from a small map of Ireland, containing a proposed project for making a main line of railway between the harbours of Kingstown and Valentia; the map is dated London, May, 1835, and carries the signature of the person then engineer to the Dublin and Kingstown Railway Company; and to the activity of some of the members of that company has fame assigned so great an influence in the councils of the late Irish Railway Commission, not only in the drawing up of parts of the report itself, but also in the selection of the railway lines, as will appear by the small map alluded to; and so highly injurious did this appear to some of the individuals in high authority, that part of the report which had appeared in the first numbers printed, was altogether suppressed in those which subsequently appeared, and this gave rise to a discussion in the House of Commons, to which the Chancellor of the Exchequer was not able to give a satisfactory reply. This transaction alone is strong presumptive evidence of the partiality and favouritism which has characterized the proceedings of the Royal Irish Railway Commission.

We have been not a little surprised to find that one of the engineers who had advocated and laid out the line of railway from Dublin to Belfast, by Newry, along the sea shore, called the coast line of railway, appears also as the engineer and advocate for the railway commissioners' inland line extending from Dublin to Armagh and Belfast. The inland line of railway is well known to be the avowed and open opponent of the coast line of railway: we conceive this proceeding to be certainly an anomaly in the jurisprudence of civil engineering. It is beyond our comprehension how a professional man could conscientiously reconcile to himself such a proceeding, or continue to possess that respect due to the integrity of his character, in becoming the professional advocate of a competing line, destructive we should think to the interests of the Coast Line Company, by whom he was originally employed. On this subject we have already, in a very forcible manner, expressed our opinion that no engineer in the employment of any of the Irish railway companies should have been employed by the commissioners in laying out railways in Ireland, that they should have been careful to have kept themselves free from any hereafter observations which might be made as to such a proceeding; but, this fair and straightforward course could not be done in Ireland, no, not even by a royal railway commission; their proceedings could not be conducted without an open exhibition of partiality and favouritism by the employment both in the south and also in the north of the engineers of various competing and rival railway companies in Ireland.

It appears that two systems of railways have been laid out through the south of Ireland by the professional engineers employed by the commissioners; one to please the Royal Irish Railway Commissioners, the other to please the companies—those systems being at utter variance with each other; we ask would it not be proper to have those important differences first examined and investigated, and then decided by an impartial tribunal, composed of the highest engineering authority which could be found, totally unconnected with either the Royal Irish railway proceedings, or those of any existing Irish railway companies in Ireland.

It is remarkable that although Mr. Nimmo, Mr. Telford, Mr. Bald, Mr. Stephenson, and other eminent engineers who were professionally employed in Ireland, to report on railroads, and that their reports state, that an income profit would be derived from them of ten, twelve, and thirteen per cent.; yet, the Irish Railway Commissioners have not noticed those statements and valuable reports. Further it appears by a printed report of Mr. Griffiths (one of the railway commissioners) on the proposed Limerick and Cork railway, that it would pay a profit of 11½ per cent., while on the other hand it deserves notice that the Irish Railway Commissioners state that the suggested railways in Ireland will only pay from 3¼ to 4 per cent.

"And through whose agency do the railway commissioners arrive at this conclusion? Why they employ Mr. Stanley, of the Stamp-office, to make their calculations; a person well qualified to close bankrupt books, and give the balance whichever way the parties pleased."—*Mr. O'Connell's Speech; House of Commons, 30th July*, 1838. And who has since been promoted to be Secretary to the Irish Poor Law Commissioners through the influence of the Chairman of the Grand Canal Company.

A cry has been set up by the jobbers in public money that Ireland is not able to maintain railroads. It may be observed that it has not yet been shown by any kind of well grounded facts, that such is the case. Because, the Kingstown Railway has been finished by private enterprise, aided by a loan from the state. The Ulster and Drogheda Railways are in progress of execution, and so would the Dublin and Kilkenny Railway, if it had not been checked in its course by the unfortunate publication of the Irish Railway Report, and also the Dublin and Limerick Railway. In all of which British capitalists had joined with the Irish companies, being perfectly satisfied, from accurate calculations, of a profitable result. Scotland has already made five railways, and there are five or six more in progress of execution in that country. And really we think that Ireland ought to be as well able to make her own railways by private enterprise, aided by British capital, as Scotland, if the public companies who have projected those works be not interfered with by the state.

Have not all the Steam Navigation Companies in Ireland been eminently successful? and are there not fleets of steamers sailing constantly from Cork, Waterford, Wexford, Dublin, Drogheda, Dundalk, Newry, Belfast, and Londonderry to the ports of Great Britain? Has not the Dublin Steam Packet Company alone raised five hundred thousand pounds sterling? And is not that company as well as all the others in a prosperous condition; these well attested facts speak volumes as to what private enterprise could effect in Ireland, *if it be not shackled by state monoply*, but aided and assisted by judicious loans from the Government, or as recommended by a Select Committee of the House of Commons in 1835.

As a high authority of the value of private enterprise applied to public undertakings, we beg to quote the following observations of Dr. Bowring:—

"Dr. Bowring observed, there appeared to him to be a unanimous feeling in favour of the communication by the Red Sea. At present it was most imperfectly carried on; but by the formation of such a company as that proposed, it would be greatly improved. An objection had been offered to the proposed plan of its being left to a private company, but that it should be taken up by the Government. He had always thought that English commerce had spread to the extent that it had owing to its being *left to private enterprise*, and that it was desirable that it should be as independent of the Government as possible. It was in this spirit that the French merchants replied to the great minister of the day, when he asked what he could do for their advantage, when they said, 'Leave us alone.' (Hear, hear. hear.)"—*Steam Communication with India. Public Meeting held at the London Tavern, Bishopsgate-street, Jan. 18th*, 1839.

Looking at the total exclusion of central Ireland, and the whole province of Connaught, from railway intercommunication by the commissioners, and at the imperfect and objectional system of railways laid out by them, both in the south and in the north of Ireland—again, at the numerous errors existing in the commissioners' maps, sections, levels, and gradients—fully authorises us in declaring that they present a mass of inaccuracies unequalled in any work that has yet been published under executive authority by any state in Europe. The Report is deficient as an exposition of Ireland's manufacturing industry; of her internal traffic; the amount of her agricultural produce; her mineral wealth; her lake and river water power; the extent of her improvable wastes and sea lands; the value of her sea, river, and lake fisheries; the number of her steam-boats, &c.; the extent of her coal and peat fuel; her lake and river navigations; the revenue of her chief towns, &c. Nor does it appear that any correct geological survey has been made of any one of the Irish counties; although a coloured map has been published by the railway commissioners, as if it really had been the result of an examination of the whole of the Irish strata, but this document is incorrect.

The effect of the Railway Commissioners' Report, clothed as it is with an official garb, has been to engender doubts in the minds of British capitalists as to the returns which they had previously expected from the money which they had subscribed towards Irish railway undertakings, in consequence of which they have hesitated to proceed with the works. This renders it imperative on the Government to repair the deep injuries they have inflicted on Ireland by the Railway Commission, and to come forward promptly to reanimate that spirit of vigorous enterprise which has been thus so unfortunately checked by reasonable and judicious loans to such railway undertakings as have been sanctioned by Parliament.

Railroads are being extended through France, Germany, Russia, Belgium, England, Scotland, and the United States of America; but, unfortunately, in Ireland the Royal Railway Commission has paralysed the progress of these works of civilization, and has sealed their doom for years to come, unless the British Executive assumes the mantle of *Engineer-General of Railways for Ireland*, and constructs them at the public expense. This Royal Commission has by its acts and writings, for more than two years past, been contriving the most unfair practices to railway companies, the deepest injury to the existing rights of private enterprise, and the total subversion in Ireland of all the freedom of the pursuits of both the Irish and British people, as connected with the promotion of those works of improvement, the offspring of human invention, and which are shedding such a lustre upon the annals of the nineteenth century.

It is very remarkable that a distinguished public character, exercising great influence in Ireland, and a strenuous supporter of the present government has lately appeared in public as a prominent supporter and advocate for the commissioners' report, and the plan of the execution of railways by the government, on their own responsibility, to the exclusion of private enterprise. It may be useful to refer to the recorded opinions of the same honourable gentleman as delivered in the House of Commons on the first appearance of the Commissioners' Report, and which appears more accurately to describe the injurious effects of that document than a more lengthened essay, for which we have shown there was ample grounds.

"Mr. O'Connell said he was one of those who was dissatisfied with the report. The commissioners had not contented themselves with reporting proper lines for railroads hereafter to be undertaken, but they take upon themselves to stigmatise those already in progress. They tell us, moreover, that no railroad in Ireland can yield more than 3½ per cent. profit. And through whose agency do they arrive at this conclusion? Why they employ Mr. Stanley, of the Stamp-office, to make their calculations—a person well qualified to close bankrupt books, and give the balance which ever way the party pleased. Really the result of this commission was a melancholy one for Ireland. These commissioners having decided that 3½ per cent. profit is the most the speculations could yield, it is now impossible to go to the Stock Exchange and get money to forward these works. The result on the whole is, that it would be useless to make railroads in Ireland. If we had not this report, works would be undertaken, and employment given to the people; and yet the Chancellor of the Exchequer comes forward to praise these commissioners—and praise more undeserved was never, in his (Mr. O'Connell's) opinion bestowed upon any men. The thing is done—Ireland is stamped—there is the report. He rose to perform a melancholy duty; he could not approve of the report, and he had only now to express his regret at the inevitable consequences which must follow from it."—*Mr. O'Connell's Speech; House of Commons, Monday, 30th July*, 1838.

STEAM BOAT INSPECTORS.

It is with great regret we learn that the Government has given way to the clamours of a few idle twaddlers, and is on the point of proposing measures in Parliament calculated to be in the highest degree injurious to all parties interested in steam navigation. These measures are said to be based on the plan of appointing inspectors to examine all machinery, and to decide upon its safety and applicability. This is a course which will certainly not only defeat the objects of its promoters, but strike a deadly blow at this important branch of public enterprise, while, at the same time, it will inflict great injustice on a particular class.

This is a measure totally uncalled for, as it is a question not to be decided by the clamour of fools, but by the evidence of facts; and to these we confidently appeal, to prove that instead of there being any degree of danger, further than is incident to all human proceedings, there is a less amount of loss of life than is to be found in any other department of foreign, or domestic communication. Let figures speak for themselves, and then we shall see the thousands of lives which are yearly lost in the merchant marine of all nations, and the numbers who daily perish on land, by accidents from coaches and other vehicles. While, if we look to other countries, and particularly to the United States, we shall find that the accidents in steam vessels far outnumber those with us. It must be remembered, also, that where accidents with steam boats have occurred, that where they have not proceeded from maritime causes, often so far from being the fault of the manufacturer, they have arisen from avarice of the owners, or the ignorance of the engineers on board. Thus, not only is there no possible reason for such arbitrary proceedings, but there is no reason for singling out for oppression a means of intercourse which has carried so many millions of persons with such an incredibly small number of casualties.

Why have not the shipowners been singled out? They count sacrifices of life by thousands where we lose tens, yet none think of attacking an interest which is powerful enough to defend itself. Neither are there inspectors of coaches to decide whether a rotten axle should run another journey or be laid aside; while, because the rights of steam boat owners are supposed to have no powerful protection, they are to be selected as a peace-offering at the shrine of vulgar prejudice and administrative ignorance.

While this novel legislation is thus uncalled for, we may see, by anticipating its results, that it has no argument on which to base its future utility. For by the introduction of inspectors, the whole talent of the manufacturers will be left at the mercy of men who, however competent in other respects, cannot fail to be guided by prejudices injurious to the cause of science, and to the interests of the parties concerned. A stop will be put to all improvement, and all experiments annihilated; and in the hands of two or three men will be left the control of all this important department. What manufacturer will run the hazard of incurring the veto of this despot, or what owner will expose himself to the loss of capital in experiments? That this will be the result, it needs but little reflection to demonstrate; for, in a science which is not yet fixed, but is ever progressive, which must be left to the decision of time, which would be rejected by the prejudices of men. Let us remember the opposition of Watt to the high-pressure engine, and the conflict of opinion which still exists on the subject. Let us imagine Watt a steam-boat inspector, and say where would now be the locomotive and the Peruvian mine engine. Let us recall the contest about the powers of the Cornish engines, or suppose Dr. Lardner deciding on the question of Atlantic steam navigation; and we may be assured that if this plan had been in activity thirty years ago, we should have been far behind; and that if it is carried on now, we shall be as victims before the power of those nations who have the sense to leave science unshackled.

Except to produce this mischief, the operations of these *obstructors* must ever be a nullity; for they must be more dispersed than poor law commissioners, or as numerous as excisemen, if they have time and power to make such an examination as shall ensure a remedy against the evils which they are intended to prevent. Their superintendence must be indeed vigilant if they can climb every chimney and poke themselves into every fire grate, while their occupation will be no sinecure when they will afford such admirable opportunities for diminishing the responsibility of the engineers, and thrusting it all on the devoted obstructors. The effect will be a check to the progress of science, no guarantee against accidents, and a less available responsibility than at present exists; while the unfortunate employers will have the benefit of all the odium of the class over whom they are spies, and the certain blame of every mischance.

If there be even a shadow of a fault, and we have shown that there is scarcely that, the proposed measure, instead of remedying the evil, by attacking wrong parties, perpetuates it and creates a greater. It is not the manufacturers who are in fault, but the cupidity of the owners or the want of instruction in the working engineers. These are the sources of the evil, if any exist; and it is to these that the measures of the American government are chiefly directed. The skill of the manufacturer no inspectional ability can regulate; but, by making the responsibility of owners and captains more direct, a more efficient remedy will be provided, and the error, if any, corrected.

In conclusion, we deprecate this proceeding as mischievous and unjust; and we call upon the manufacturers and steam-boat owners to unite and oppose this measure by all the means in their power. It was by such combination that the railway proprietors last year defeated the government in a similar invasion on their rights and property; and in this case, even should not the entire proceeding be annulled, at any rate many of its ill effects may be removed, while the legislature may be brought to entertain sounder opinions on the question. This association of persons interested in steam-boat traffic has now become imperative; for not only in this instance, but in others, measures are contemplated for inflicting severe injury on it. The question of tolls on passengers is of paramount importance, while the proposal of inspectors equally calls for resistance, and the steam-boat proprietors may feel assured that it is only by union and prompt measures that these present evils can be avoided and future safety insured.

ON THE GENERAL THEORY OF THE STEAM ENGINE.

Notwithstanding the number of years which have elapsed since the invention of the Steam Engine, and the immense extent to which it is now employed, as well as the great importance at present attached (particularly in some of its applications) to the perfection and economy of its working: yet our knowledge of the general theory of its action is still but very limited. We were led to investigate this subject more fully on the perusal of a pamphlet which appeared in the course of last year, entitled, "A New Theory of the Steam Engine," by the Chevaler G. de Pambour, and purporting to be an analysis of a memoir by the same author, which was read at the Institute Royale of France, during the year 1837. The author, after shewing the inaccuracy of the ordinary mode of calculation used to determine the effects and proportions of steam-engines, exposes what he calls his new theory, by means of which he undertakes to solve all problems relating to those effects and proportions. M. de Pambour's theory consists essentially in the following laws:—

1. That the pressure in the cylinder is strictly regulated by the resistance on the piston and by nothing else.
2. That the velocity of an engine is determined by the quantity of water which can be evaporated in the boiler in a given time, and
3. That the pressure in the boiler is indifferent, provided it be at least equal to the pressure in the cylinder.

The last of these laws is of very little consequence, since it can have no effect on any of the calculations; but the two former serve to solve all the problems relating to steam-engines; for, having ascertained the quantity of steam generated in the boiler, and transmitted to the cylinder, as well as the velocity of the piston, which gives the volume occupied by that steam, we find its density and elastic force, and consequently the resistance on the piston. Inversely, either of the two other quantities might be determined, the rest being given. The principal difference between M. de Pambour's and the ordinary mode of calculation is that, according to the former, the effect of an engine is measured by the quantity of steam generated in the boiler; and according to the latter, by the quantity used in the cylinder: both which quantities must be equal, if correctly measured; unless, of course, there be any discharge through the safety valve, in which case M. de Pambour's method would fail, if he had not the means of measuring or estimating the quantity so lost; in place of which he assumes (for locomotive engines) an average loss of one fourth of the whole of the steam generated, and therefore considers the effective evaporating power of a boiler to be three fourths of its total evaporating power. Now this clearly cannot be true for all locomotive engines, nor even for one engine on all occasions; the safety valve will be more or less open, according to the load of the engine and the pressure in the boiler; and the discharge of steam through the valve, when open to the same degree, will depend on the pressure in the boiler. The latter circumstance would, however, have but an imperceptible influence if the difference of pressure were not very considerable, the velocity of efflux being directly as the effective pressure, and inversely as the density of the steam.

The manner in which M. de Pambour arrived at the average loss of steam through the valve, shows that it is seldom, if ever, correct. He first ascertained what rise of the valve was necessary for the discharge of all the steam generated, which corresponds to different numbers of degrees of the spring balance for different boilers, and then observed the actual rise in a certain number of experiments made with different engines; he then compared the sum of all those rises with the sum of all the rises necessary to give egress to all the steam generated in the various boilers, taken once for each experiment. In eleven experiments, the sum of actual rises was 12 degrees of the various spring balances, and the sum of rises necessary to give egress to all the steam, in each case 46·5 degrees: namely, five experiments, with engines requiring 5 degrees, give 25; three experiments, with one requiring 4, give 12; two experiments, with one requiring 3, give 6; and one experiment, with an engine requiring 3·5, gives 3·5; which numbers, when added together, will be found to make up 46·5. The ratio of 12 to 46·5 being very near one-fourth, this has been taken as the average rise of the valve, and consequently as the average loss of steam.

Thus we see that we can make no use of the constant coefficient 0·75 in determining the effective evaporating power of a boiler; for it might very well happen that only one-eighth should escape through the valve, in which case we should find the effect one-seventh too little; and if in any case there should be a loss of one-half of the steam, then we should arrive at a result 50 per cent. too great.

But, setting aside the error we should commit by taking the average rise of the valve, how are the following facts to be accounted for? In the table of experiments at page 229 of M. de Pambour's "Treatise on Locomotive Engines," we see that the Fury ascended the Sutton inclined plane, with a load equivalent to 183 tons on a level, at a speed of 13·33 miles an hour, the rise of the valve being 5 degrees of the spring balance, which is sufficient (see the table at page 175) to allow of the escape of all the steam generated in the boiler. We also find (page 232) that the Vesta ascended the same inclined plane, with a load equivalent to the former, at a velocity of 3·25 miles an hour, when the rise of the valve was equal to 3·5 degrees of the spring balance, or sufficient, according to the above-mentioned table, to give issue to all the steam. Also, (see page 234), the Vulcan is stated to have ascended the same inclined plane, with a load equivalent to 188 tons on a level, at a velocity of 11·42 miles an hour, the safety-valve being sufficiently open to allow of the escape of all the steam; and, in the same page, the same engine is stated to have ascended the Whiston inclined plane on another occasion, with a load equivalent to 186 tons on a level, at a speed of 18·75 miles an hour, the safety-valve being open to the same degree as in the preceding case.

Supposing the observations to have been correctly made, we can only account for these apparent anomalies by supposing the evaporation to have been more rapid in the cases quoted than during the experiments which had been made, with the view of determining the rise of the valve necessary for the discharge of all the steam generated; for it is the absolute quantity discharged, and not the proportion, which is determined by the size of the aperture. It is, therefore, exceedingly difficult to deduce the power developed by an engine from the evaporating power of the boiler, whenever there is any escape through the safety-valve.

Before leaving the subject of these experiments, we must observe that, from their nature, they were not susceptible of that precision which is necessary to allow of their results being made the basis of accurate calculation: for, on account of the irregularities of the road, the circumstances were continually varying, and the momentum of the trains rendered the effect of those variations less perceptible than it ought to have been.

It is an essential part of the Chevalier de Pambour's theory, that the pressure in the cylinder is independent of the pressure in the boiler, and depends solely on the resistance to be overcome. This is, to a certain extent, true; but we cannot allow that the pressure in the boiler is altogether independent of the pressure in the cylinder, for it cannot be denied that the law of the flowing of elastic fluids must obtain in this, as well as in all other cases. The pressure of the steam in the cylinder being, therefore, equal to the resistance on the opposite side of the piston, and the velocity of the piston being determined by the *effective evaporating power* of the boiler, which we readily allow, the pressure in the boiler will necessarily be such as to cause a corresponding efflux of steam from the boiler into the steam pipe, and through that into the cylinder. If at any moment this were not the case, the pressure would immediately begin to adjust itself, and would finally remain fixed as soon as it had arrived at that point: suppose, for example, that the pressure in the boiler is too low to cause an efflux at a sufficient velocity to supply the cylinder; the pressure will instantly rise until it be sufficient to cause an efflux at the velocity which will then be required, which is less than before, as the density is greater. This circumstance has been entirely overlooked, or rather neglected, by M. de Pambour, as well as the effect of velocity on the resistance of the air to the trains, which must considerably affect the results of his experiments.

Before entering upon the general discussion of the theory, when we shall have occasion to revert to M. de Pambour's works, we shall briefly advert to a paper *on the application of steam as a moving power*, which was published in the second volume of the "Transactions of the Institution of Civil Engineers." We should not have stopped to notice this paper, but for the medium through which it has been brought before the public, which naturally gives a certain degree of importance to everything therein published, as it must first obtain the sanction of a body of men, who, from their profession, and the eminence which some of its members have attained in that profession, have necessarily considerable influence over the opinions of those who are personally unacquainted with mechanics.

The author of the paper in question appears to have had less in view the advancement of science, as the title seems to promise, than to create a doubt in the public mind as to the correctness of the official reports of the duty performed by the Cornish engines; and he appears to have persuaded himself that he has demonstrated, on scientific principles, that those engines *could not* have performed anything like what they are reported *to have done*, and, consequently, that the reports are erroneous; but we hope to be able to show, satisfactorily, that he is labouring under a delusion.

We will, for the sake of argument, allow that the combustion of 7lbs. of coal is required to convert one cubic foot of water into steam, and consequently that the quantity of steam generated by the combustion of 84lbs. of coal under a pressure of 15lbs on the square inch, and recondensed without having been allowed to expand, will raise 44,467,500lbs. one foot high and no more. This we will allow to be the greatest effect that can be accomplished by atmospheric steam, and yet we assert the possibility of raising not only 70,000,000 but double that quantity, one foot high, by the combustion of the same quantity of coal, by making the steam in a condensing engine perform a part of the stroke at a high pressure, and then causing it to expand through the rest, though it should be reduced at the end of the stroke even to a lower pressure than that of the atmosphere. But Mr. Palmer attempts to demonstrate that "high pressure steam, when applied expansively, cannot produce so great an effect as atmospheric steam, thereby meaning to infer that no high-pressure engine can perform the same amount of duty as a condensing engine, both consuming equal quantities of fuel." He professes to draw his arguments from the established laws of nature, and adduces the following theorems; to prove which he very unnecessarily occupies seven pages, and then never makes any use of them; indeed, if he had, they would rather have shown an advantage, both in the use of high-pressure steam and in expanding it.

1. The sum of sensible and latent heat in steam is a constant quantity, viz., about 1172 deg. F.

2. All matter (steam, of course, included), whether solid, liquid, or gaseous, from the most dense and refractory to the least ponderable, evolves caloric on compression, or increase of specific gravity, and absorbs caloric on dilatation, or when its specific gravity is diminished.

3. To convert equal quantities of water of any assignable temperature, and under like pressure into steam of given temperature and elasticity, requires equal weights of fuel to be expended; but, although equal weights of water must absorb equal increments of caloric, when atmospheric steam is generated, it does not follow that all the caloric absorbed in high-pressure steam is exclusively supplied by the fuel expended. The law maintained is simply this, that the same causes produce the same effects.

4. Steam of two, three, or more atmospheres elasticity, is not composed of two, three, or the like number of volumes of water contained in an equal volume of atmospheric steam, when generated under the same barometrical pressure, but contains proportionably less water as the pressure under which the steam is generated increases.

From the first of these theorems we conclude that whatever be the pressure of steam before expansion (so that it be in that state called saturated, that is, as dense as it is possible for it to be at its temperature), if its density be reduced by expansion to that of steam generated under any given pressure, it will assume the latter pressure and the corresponding temperature, and will therefore be still in the saturated state; so that if steam enter the cylinder of a steam-engine at a pressure of three atmospheres, and, after having performed a little more than one third of the stroke, be made to expand through the rest, so that its density shall be reduced at the end of the stroke to that of steam generated under the pressure of the atmosphere; then the cylinder will be filled with steam in every respect the same as atmospheric steam, and, by the third of the above propositions, generated at the same expense of fuel as that quantity of atmospheric steam; and yet the effect will be about double what it would have been if the steam had been worked at the pressure of the atmosphere throughout the stroke, for the mean pressure is somewhere near two atmospheres. The fourth proposition shows that the economy of fuel is greater, the greater the pressure is at the commencement of the stroke, for the consumption of fuel is in proportion to the density, which, by the last named proposition, does not increase so rapidly as the pressure. The steam will thus, at a higher pressure, be required to work at full pressure during a greater portion of the stroke than if its density increased uniformly with its pressure, in order to fill the cylinder with steam of a given density, which shows that the mean pressure, and consequently the effect, will be greater, the higher the pressure at the beginning of the stroke.

The almost incredible advantages to be derived from the expansion of steam becoming every day more generally known, from the experience of the Cornish pumping engines, and the adoption of this principle constantly extending itself in consequence, as every body is desirous of availing himself of those advantages, it becomes absolutely necessary that the action of the steam, during that portion of the stroke of the piston through which it expands, should be better understood than it is at present, in order that we may be enabled to make a more exact calculation of the power exerted under such circumstances.

The present rule for calculating the mean pressure on the piston, when the steam is used expansively is extremely defective; it supposes the steam to lose none of its temperature during its expansion, while (neglecting that lost by radiation, which is a comparatively trifling quantity) the caloric absorbed by the steam itself in consequence of its dilatation, which no clothing of the cylinder can prevent, amounts to many degrees, particularly if, in order to obtain the greatest advantage possible from the principle of expansion, the steam be cut off after the piston has performed but a small portion of the stroke. In this case, the application of the law, that the pressure and density increase in the same ratio, would make the mean pressure appear much more considerable than it really is. We shall attempt, in a future paper, to bring this branch of the theory—we will not say to perfection, for that were presumption, but as near that limit as can be required for practical purposes.

MEMOIR OF RICHARD TREVITHICK.

While the biography of literary men has received full attention, although rarely presenting any object of interest, the lives of men of science, deeply enwoven as they are with the history of the pursuits in which they are engaged, have frequently remained unknown, or too often neglected. Nothing, however, can be more interesting to the student, or better calculated to animate him in his career, than the perusal of those efforts of application and genius, which have overcome impediments apparently unconquerable, or created a giant work from the rudest and most incongruous material. It is here that we find the most practical lessons of perseverance, and the most effective stimuli to our exertions: the slow and arduous path to fame is thrown open to our view, and we are taught not to be daunted at the most protracted labours, and not to neglect the slightest effort for success. When, too, our own countryman is the theme, we warm as we take pride from the halo shining on our native land, and we feel the exalted nature of that genuine fame which is not restricted to selfish enjoyment, but brightens the whole human race.

It is not unaccountable that oblivion should often encloud the memory of the greatest practical geniuses, for their early labours are hidden in the obscurity of the study or the workshop, and then, after battling against the efforts of the malignant, or the immoveable resistance of stolidity, the inventor is long dead before the contest is ended, or his works are successfully established. In the meanwhile, the progress has been so slow and so gradual, that, like a plant, casts off all semblance of the seed, so the name of the author has ceased to keep company with his labours. Often, too, where a name survives, we are led to distrust, when, like that of an Arkwright, it has supplanted the rightful owner.

One of the neglected benefactors of the human race is the subject of the present notice, whose memory, except in his native mines, is among his fellow-countrymen almost consigned to oblivion. At the present period, therefore, when we are beginning to enjoy the benefits of steam locomotion, we have thought that it would be acceptable to present some account of the engineer to whom our country is so much indebted for his efforts in promoting this improvement. We can only regret that this task had not fallen to the lot of others possessed of more ample materials for doing justice to the subject. Although we knew Trevithick during a most active portion of his career, yet the lapse of years soon renders the memory of incidents vague and imperfect. We know no one, indeed, who could better have fulfilled this task than a late President of the Royal Society, Trevithick's fellow-countryman and friend. Many errors of omission must therefore be excused, and many misrepresentations palliated; and it must be remembered that we are not so much to blame in committing faults, as that we merit protection for attempting what has not been done before.

Richard Trevithick originally moved in that class of society called in Cornwall the Captains of Mines, for which profession he was educated in the mine counting-house as clerk, having as one of his colleagues at that period Richard Griffiths, now the Chief Government Engineer in Ireland. Cornwall, at that period, was something different from what it is now, the mail road not extending beyond Exeter, the Cornish language just extinct, and the great influx of London capital not having commenced. This state of affairs, consequently, did not allow of any superior education; and although belonging to the mining aristocracy, Trevithick had little but the routine of practice to qualify him for the profession in which he was destined from his birth to move. Of his early years, therefore, it is unnecessary to say more, than that his career was distinguished by the introduction of many improvements into the operations in which he was engaged, and by a promise of distinction which his future exertions did not belie.

The mine captains, from their inter-marriages, were nearly all related, and among Trevithick's nearer cousins were the Vivians. Andrew Vivian, one of these, was a man of greater worldly abilities than most of his class, and fertile enough in all those expedients which are useful in raising money. With him Trevithick engaged in several affairs, he finding work, and Vivian supplying money. It was in partnership with him that, in 1802, Trevithick, while at Camborne, took out his patent for the high-pressure steam engine.

About the year 1723, Leupold, a German philosopher, in his comments on Papin's apparatus in the Theatrum Machinarum, had given the first idea of the application of steam on the high-pressure principle, but his suggestions remained without any practical results. Watt indeed had made some allusion to this principle in his attempts to obtain a locomotive power, but at any rate was not able to avail himself of it, even if he understood its application, and to the last day of his life displayed an obstinate prejudice against it. It does not appear that Watt had then read the Theatrum Machinarum, and it is not likely that Trevithick in his Cornish seclusion ever saw it, so that he has the merit of invention as much as of application. The introduction of this improvement gave increased powers to steam, and it is of that importance, that Stuart, not likely from national sympathy to be over-prejudiced in favour of an Englishman, is even inclined to date the era of the steam engine from this invention. It is certain that independently of its merits, this application of steam power is already of paramount importance from its great extension. It affords the means of locomotion on all the railways in the world, propels the swarms of American steamers, and is greatly used in manufacturing operations.

In 1804, Trevithick had the opportunity of trying his engine on the Merthyr Tydvil tramroad as a motive power applied to a carriage. The engine had an eight inch cylinder, and the piston had a stroke of four feet six inches; it travelled at the rate of five miles an hour, and drew as many waggons as carried ten tons of iron, without requiring any water, for a distance of nine miles.* Stuart says that the great obstacle to its introduction at this time was the supposed want of adhesion, or hold of the wheels upon the rails, to effect the locomotion of the engine.

Trevithick and Vivian erected several of their high pressure engines in Wales and other places, and it was about this time, although we do not know whether before or after the experiment on the Merthyr Tydvil tramroad, that Trevithick put into operation the first locomotive engine in London. In the great metropolis Trevithick found ample support in his countryman, Davies Gilbert, the Earl of Stanhope, Mr. Isaac Rogers, Mr. Samuel Rehe, Mr. Henry Clarke, and others connected with his native county or the cause of science. The engine he used was about the size of an orchestra drum, and which he attached to a phaeton between the back wheels. With this carriage an experiment was made in Lord's cricket ground, at Marylebone, several men of science alternately steering it, and expressing their perfect satisfaction as to the ease with which it was directed. From hence it was steered down the New-road, and Gray's-inn-lane, to the coachbuilder's, whence the phaeton was obtained. Thus it passed over ground, since the site of Hancock's experiments, and perhaps ultimately destined to be witness of the final triumph of this branch of locomotion. The next day Trevithick took this same engine and exhibited it in a cutler's shop, working the machinery; which was one of his essays, to show its general applicability. Subsequently he had a temporary tramroad constructed within an enclosure on the ground now occupied by Euston-square. This road was of an elliptical form, and on it he ran his locomotive. It was opened to the public as an exhibition, and people crowded to see it, but the second day Trevithick, in one of his usual freaks, removed the engine, and, to the great disappointment of visitants, closed the ground. This he did under the impression that it was better to let the affair drop, until he saw the opportunity to avail himself of it advantageously.

Another occupation of his metropolitan career was the tunnel under the Thames, in which he owed it only to his own pertinacity that he disappointed both the public and himself. Ralph Dodd, an engineer of some note of the last century, was the first to commence operations for a tunnel under the Thames from Gravesend to Tilbury Fort. His plan was to avail himself of the chalk stratum which he supposed to run under the bed of the river, and he expected that the chalk quarried out would sufficiently pay the expenses of working, leaving its subsequent use as a viaduct to afford a handsome income. As was mentioned by a correspondent in one of our late numbers,† he obtained an Act of Parliament for his plan in 1799, with power to raise 30,000l., and to increase his capital in case of need to 50,000l., his estimate being only 15,000l. The work was commenced, and proceeded for about three years, but was ultimately stopped on accouut of the expense of drainage. He had gone on the assumption that the chalk would be in one solid stratum, and that he should not be embarrassed by water, having in his estimates allowed only 1780l. for this purpose, and treated the expense as merely contingent. He found, however, such great inconvenience from under-springs rising through fissures in the chalk, that as we have said, he was obliged to abandon the project. This tended to throw a damp on such plans, and when Trevithick proposed a similar tunnel under the Thames at Rotherhithe, he found a natural reluctance to support any such undertaking. Several of his friends, however, raised a subscription to enable him to make an experiment on a small scale, and the result was anxiously awaited to justify an appeal to the public for carrying out the entire plan.

In 1809, therefore, Trevithick was employed in running a small driftway parallel to the bed of the Thames. The committee of subscribers justly felt every assurance of the success of the undertaking, for the operation was extremely simple, while they had entire confidence in his skill and ability, from the experience he had gained in similar underground mining works. We have tunnels four miles in length to some of our canals, and abundance of communications in the mining districts under the surface of the earth, and even beneath the sea; but notwithstanding the ease of such a work, extraneous causes have always hitherto prevented this kind of viaduct from being used under rivers. Trevithick, to save labour and expense, committed the usual fundamental error of not going deep enough below the bed of the river, the object in his case being a close-run endeavour to keep at the least possible distance from it. Had his experiment been concluded, this would have enabled him to give a plausible original estimate at any hazard of subsequent increased expense. This error, however, was not productive of much inconvenience to him, nor was it the immediate cause of the abandonment of the enterprise, for he carried his driftway to a greater extent without impediment than has been done in any other attempt. It was not until he had gone 930 feet* under the river, that he encountered any obstacle, when he got into a hole in the muddy bottom of the river, and at one time a piece of uncooked ship beef, which had fallen from one of the vessels, drifted into the works. Although the Corporation authorities refused to allow him any facilities, he managed to get this hole stopped, and again went on with vigor; he carried on the excavation at the rate of from four to ten feet per day, and soon completed a thousand feet, to the great joy of every one concerned. On arriving at this distance, according to his previous agreement with the committee, Trevithick was to receive a hundred guineas, which, after a verification of the work by a surveyor, were paid to him. This surveyor was appointed by the subscribers to check Trevithick, and in giving in his report, confirming the measurement, stated that the line had been run one foot out of the perpendicular. This statement Trevithick took in high dudgeon, and chose to consider it as a deep reflection on his engineering skill to have deviated one foot in a thousand. His Cornish blood was excited, and with his usual impetuosity, he set to work to disprove the assertion, without any regard to consulting his own interest, or embroiling himself with the committee. Of all possible contrivances for effecting this object, he adopted the most absurd, which was no less than to make a hole in the roof of the tunnel at low water, and to push through a series of jointed rods to be received by a party in a boat, and then observed from the shore. Even had he been successful in carrying out this process, it would have afforded no criterion of the precision of the work, as the set of the current would necessarily have swerved the rod. Trevithick was employed in the driftway in carrying out this contrivance, and as delays of course ensued in fitting together the rods, the gully consequent on the opening in the roof ultimately admitted so much water as to render a retreat necessary. With a moral courage innate to his character, and worthy of a better cause, he sent the men on before him, and very nearly fell a sacrifice to his devotion. It has been already observed that the driftway was parallel to the bed of the river, and consequently curved; it necessarily happened, therefore, that the entering water would lodge, syphon-like, in the bottom of the curve, at which part, on Trevithick's arrival, he found so much water as hardly to be able to escape, for as he ascended the slope on the other side, and climbed the ladders, the water rose to his neck. It is needless to say, that this act of rashness was the death-blow to the project, while it added the climax to the many acts of inconsistency with which Trevithick's erratic career was disturbed. On a subsequent occasion, being cross-examined as to this occurrence while witness on a trial, he admitted the fact of his ruining the works, and his determination in any similar circumstance to defend his own character at whatever sacrifice to other people. The work thus ended after having reached 1,011 feet, and remains within a hundred feet of its proposed terminus, a melancholy monument at once of his folly and his skill.

After these events Trevithick returned to Camborne, and we now approach another of those epochs of his life, in which his labours were again destined to be followed by the most extended results. Here we have an instance of the operation of those trains of finite causes, which, while they are sometimes productive of the most unexpected advantages, too often baffle all human expectations and arrangements.†

Uvillé, a Spaniard, seeing the decline of the American mines, from the insufficient power of drainage in the old works, was desirous of adopting the English method of pumping by steam. For this purpose he came to London in 1811, but his efforts were baffled by the difficulty of transporting such cumbrous machinery over the mountain districts, and the diminution of power which the atmospheric engines would sustain when worked in the rarified atmosphere of the elevated mine countries. When on the point of departing from England, frustrated in his object, he chanced to see a finished working model of Trevithick's engine, exposed for sale in the shop of Mr. Roland, in a street near Fitzroy-square. This model Uvillé carried to Peru, and to his inexpressible joy he had the pleasure of seeing it work with success on the high ridges of Pasco. Again encouraged in his favourite plan, he entered into partnership with two rich merchants of Lima, and obtained from the Viceroy of Peru the privilege of working some of the neglected mines. He once more started for England, and while on his voyage, talking with Mr. Teague, a fellow-passenger, of his anxiety to discover the inventor of the model, he was most agreeably surprised to hear Mr. Teague reply, "that Trevithick was his near relation, and that he could bring them together within a few hours of their arrival at Falmouth."

Uvillé continued with Trevithick for some months at Camborne, profiting by his instructions; he then made a tour under his guidance in several of the mining districts, and afterwards went to Soho to consult Boulton and Watt. Whether, however, it was their jealousy of Trevithick, or their genuine want of resource on the subject, they gave Uvillé no encouragement as to the success of his enterprise. The great elevation of the mines, the difficulty of the precipitous roads, and the absence of means of transporting heavy masses of machinery, appeared to those engineers insurmountable obstacles, and disinclined them to engage in such a difficult undertaking. On the refusal of these capitalists to assist, Trevithick himself undertook to furnish the necessary engines; and in September, 1814, Uvillé embarked at Portsmouth for Lima, with three Cornish miners, and nine of Trevithick's engines.

Long before this period Trevithick had married a Miss Harvey, a lady of good connections; her brother subsequently acquiring a large fortune. By her Trevithick had several children, and it will prove at once the love he entertained for her, and his spirit of perseverance even in trifles, that during his long courtship he never missed walking every evening several miles to visit her. Dissensions had, however, arisen in his family, and he was more prepared to engage in that distant career to which he was now invited.

Uvillé was received at Lima with the greatest honours and rejoicings, and landed with his cargo under a royal salute. It was not until the middle of 1816 that he was able to surmount the local difficulties of transport, and place the first engine in operation. Trevithick, however, had nobly armed him against the antagonist obstacles, and all that his ingenuity could suggest had been put into practice. The machinery, simplified to its greatest extent, was so divided as to form adequate loads for the weakly llama, and the beams and boilers made in several pieces were transported over precipices, where a stone may be thrown for a league. The engine erected at Tauricocha, in the province of Tarma, was put into operation, and in the presence of the government deputies drained the first shaft of the mine of Santa Rosa, one of the Pasco district. The greatest anticipations were created, and amid the profusion of honours showered upon the projectors, nothing was wanted but the presence of the meritorious inventor himself.

Trevithick had in these latter years been fully as active in his contributions to the cause of science, as in any previous portion of his career. It was he who suggested the improvement on steam boats by propulsion at the stern, which is now the subject of experiments at London and at Liverpool. He considered that a spiral wheel revolving at the stern of a vessel was preferable to the use of side paddle wheels, and we believe that a vessel something on this principle is now about to make the trial voyage across the Atlantic.

Another contribution of his to steam locomotion was his revival of giving motion to the engines by means of the re-action of the steam made to spout against the atmosphere.

In 1815 he effected a great improvement in his high pressure engines, by forming the piston so that a ring of water should run all round it, and render the whole air-tight; as he found in practice that a very moderate degree of tightness in the packing produces this result.*

Trevithick was now actively engaged in England preparing for his departure. He had constructed several new engines, and an apparatus for the Peruvian Mint; and his attention was directed to an object of the greatest importance, to remedy the growing scarcity of quicksilver, by constructing furnaces for purifying the silver ore by fusion. At last, in October, 1817, Trevithick, Robinson Crusoe like, gave up all his property in England, and leaving it to his wife and children, set sail for Peru.

In February, 1817, he arrived at Lima, where his presence excited the utmost enthusiasm. He was received by the government and the people with the greatest honours, while the official announcement of his arrival in the Gazette created the highest expectations of the whole population. He had immediately an audience of the Viceroy, and the Lord Warden of the mines was directed to escort him with a guard of honour to the seat of his future labours. The principal men of the mining district came many days' journey to Lima to see and welcome him, and all exerted themselves to testify their esteem for the well-deserving Don Ricardo Trevithick. Never, perhaps, was European so well received in the New Indies; it was not Las Cases coming to rescue an injured population from oppression, but it was a man of science who had arrived to augment their old resources, and to create new mines of wealth. It was the first benefit which they had received from the Old World, and it is not surprising that an ardent people received Trevithick with as great enthusiasm as Columbus had once awoke in Spain.

The exertions of this great man were crowned with success, and he was equally rewarded by their profitable return, and the gratitude of the people. The produce of the mines augmented to an unexpected degree, and the coining machinery was increased six-fold; his companions united in expressing their obligations to him, and the authorities were not remiss in showing how they appreciated them. We understand that he was invested with the title of a marquis, and was created a grandee of the Spanish empire, while the Lord Warden of the mines even proposed to erect his statue in massy silver.

In these employments Trevithick was engaged for many years; but at last the political dissensions, and his own wandering disposition, induced him to wish to leave the country. This was no easy matter: for the veneration with which he was regarded as a benefactor sent from Heaven, made the people regard his absence as a public calamity, and take every measure to prevent his departure. At last he made his escape, through dangers which few, less adventurous than himself, could have encountered; and, after escaping the terrors of the mountain and the desert, and the arm of the wandering savage, he again arrived safely in England, where he was about the period of the great panic in 1827.

Here he endeavoured to raise capital to carry on some of his colossal projects, but with his usual ill-success—for those who knew his skill, feared the waywardness of his character; and those who did not, were repulsed by the giant nature of his enterprises. It was in vain he urged his own success, and represented the boundless resources of the Andean territory. He had the mortification to find his provision for his own fortune nullified by the ignorance and timidity of those with whom he sought to participate. While in America he had acquired large tracts of land, and on one estate had a mountain of copper ore, which, like the hill mines of Potosi or Montserrat, it would take centuries to exhaust. Here he proposed to construct railways, and, by the aid of capital and machinery, make the shores of the Pacific as great a mart for the produce of the earth, as those of his own native promontory.

Don Ricardo again returned to the New World, and resumed his labours for the benefit of the American people; for, it must be observed, that however he may have been remunerated, and how much so ever he may have desired to advance his own interests, yet the apathy of his countrymen ever prevented him from carrying out his own wishes, or being any other than the great regenerator of American riches. He died, indeed, comparatively poor, and left, we believe, little other inheritance to his family than the grandeur of his name and the glory of his works.

In his person and manners he seemed formed to sustain the arduous contests to which he was destined. The robustness of form, inured by years of toil and fatigue, was reflected by the innate self-confidence of his disposition. Blunt, but not rude, he maintained his opinions with honesty and power, and was only in fault that too frequent success made him adhere to them with pertinacity. In his moral character he maintained with propriety all the social duties. Kind to his family, he was ever ready to make any sacrifice, although the meddling of others may have created dissension in his domestic circle; while as a friend none, perhaps, could be more relied upon, for his feelings of confidence survived repeated disappointments and betrayals. His mental powers are best appreciated by the events of his life, for we may be assured that if no one be great without some divine assistance,* so few have done remarkable things without having in some degree participated in their greatness. His genius was of the highest order, while those difficulties which his invention could not dissolve were overcome by his perseverance. His self-education also allowed him to borrow little from

* Historical and Descriptive Anecdotes of the Steam Engine, by Stuart, p. 520.

* Nemo unquam magnus fuit sine aliquo afflatu divino.—Cicero.

others, but made him dependent on himself; and this confidence was rarely in vain, for his errors were always less those of judgment than consequent upon a hastiness of disposition, which, as it had met with but little sympathy from the world, was but too apt to despise it. His skill in providing for all occurrences was rarely baffled, and could not easily be surpassed, while his original and gigantic conceptions, however much beyond the progress of his age, were seldom beyond the bounds of ultimate practicability.

That his name is but slightly known, and his labours consequently little appreciated, is by no means a result of their unimportance, but the effect of concurrent circumstances, which, as they can elevate insignificance, too often obscure merit. When he had conceived a plan by the resources of his mind, and confirmed it by experiment, the very vastness of it surpassed his means of execution, and prevented it from being carried into effect. He was himself no financier, and the associations he formed with Vivian and others were either insufficient in their extent, or turned more to the profit of his colleagues than himself. It was true that he left no means unsought of obtaining the assistance of others, but those who had capital feared to engage in enterprises to which they were unaccustomed, while those used to business had no disposition to deviate from the track in which they were long practised and successful. It is the nature, indeed, of great monopolies, that their very success engenders want of activity, for none feel so little inclination to engage in new processes as those who are accumulating wealth by old ones. It is this that deadens the progress of the iron trade, of distilling, and many others; and the manufacturers, instead of supporting new inventions, spurn them as associates, and trample them down as rivals. It was the support of this influence which gave power to Watt, while it cramped the energies of Trevithick; for without the aid of Boulton, the former might have wasted his life in experiments, or, Hargrave-like, have been supplanted by another Arkwright. Trevithick wanted but this to compete with Watt in worldly prosperity, and he wants not this to equal him in the height of his genius, the greatness of his works, or the wide-extending influence of his inventions.

That the memory of Trevithick has not received the honours which have been conferred upon others, is a neglect which has been shown to many of our greatest names, and proceeds less from our want of veneration for men of genius than from our national character. We do not, like Frenchmen, dread a rival near the throne, nor are we, like Americans, fearful of others denying to us what we are scarcely known to possess. We are rich enough in illustrious names to consider their admission in our domestic habits and our thoughts as a sufficient sacrifice to fame, and it is only on the instigation of some provincial that we raise statues to those who live in our hearts. Our population in the north, however, less fertile in their contributions to the shrine of genius, and more remarkable for local preference than extended sympathies, give a greater share of admiration to the few of whom they dare to boast. The English, in acceding to their suggestions, while they commemorate inferior names, create mementos of their own neglect. While, therefore, there are three memorials of Walter Scott to one of Shakspeare, and to Milton none, we must not consider the many tributes to Watt as emblems of superiority, but as proofs of a better fate. It is to this that we must attribute that a statue is rising to Watt in Manchester, while Brindley's merit still relies upon the glorious memory of his canal. We may carry, however, this self-confidence too far, and where we meant only to show hospitality, may have brought in strangers to master our own children; when we see the generosity of the American Congress to the spurious claims of Fulton, and the gratitude of Peru for the labours of Trevithick, we are called upon to offer some honour to his name, and to show that we are as proud of the inventor of the high-pressure machinery as we are conscious of the benefits we derive from his railway locomotives. But, neglect him as we may, the name of TREVITHICK will live while his engines annihilate space in the Old World, and in the New control the current of the Mississippi, and disgorge the mountain riches of the Cordilleras.

MR. OLDHAM'S SYSTEM OF WARMING AND VENTILATING,

AS ADOPTED AT THE BANK OF ENGLAND AND BANK OF IRELAND.

Sir,—As the best mode of heating and ventilating apartments and buildings is still an undecided matter among scientific men, I avail myself of your journal to draw public attention to what appears to me to be the best among the various plans and patents of the present day.

At a late meeting of the Royal Institution, Professor Brande, in the course of his Lectures on Heat, and in considering its transmission and diffusion by means of currents, pointed out the advantage of aiding the operation of those currents by mechanical means.

In illustrating this mode of conveying heat where extensive apartments are to be acted on, and where either a large volume of air or a great quantity of heat may be required, the Professor described the operation and effect of an apparatus successfully adopted by Mr. Oldham, of the Bank of England, in which building it has been in use during two years, having previously been adopted by him in the Bank of Ireland, and where it has been in operation during sixteen years.

When heat is conveyed by means of natural currents, these are necessarily, and exclusively, due to the difference in the temperature and specific gravity of the column of air, when heated, relatively with that of the surrounding atmosphere; the force of these currents, and the body of heat they are enabled to transmit, are therefore necessarily languid, compared to what may be effected by artificial means.

That steam is the best medium for the transmission of heat is now too well known to require much illustration. Its superiority over water (independently of the greater facility with which steam is conveyed to a distance) is derived from the extraordinary quantity of heat which water contains when in the state of vapour—a cubic foot of water, in the form of vapour, having the power of giving out nearly eleven times more heat, than the same body of water could when in its liquid state.

The mode hitherto adopted in many establishments, and in the large cotton-factories, is that of conveying steam through a continuous series of cast-iron pipes, so arranged and extended, through the several apartments to be heated, that each shall be supplied with a given length and surface of pipe, proportioned to the dimensions of the apartments to be heated.

This is manifestly a mode attended with great inconvenience and expense in the conveyance of such pipes, in their liability to leak; and in the want of uniformity in the temperature of the several parts of the rooms in which those pipes are introduced. But there is yet another and more formidable evil attending this mode of heating, namely, that while it merely conveys heat to the already existing air in the chambers to be heated, it has no relation to the condition of that air, or the supply that may be required, or the changing and purifying the same. In a word, the system, by means of steam-pipes, has the power of heating, but not of ventilating. It has no relation to the purity or impurity of the air to which it imparts the heat; and it is a fact, that giving an additional supply of heat to an apartment may even be prejudicial, inasmuch as such apartment may require ventilation, that is, *change* of air, rather than heat.

Now the process of heating adopted by Mr. Oldham has this peculiar and distinguishing characteristic, which gives it a claim above all others, namely, that it both heats and ventilates at the same time, to any extent, and with any required rapidity.

As far as health and comfort are concerned, heating and ventilation should never be separated. Mr. Oldham's process and apparatus most effectually supplies this desideratum.

Doctor Ure, in his inquiry into the modes of warming and ventilating, observes, that "the great principle of ventilation is, never to present the same portion of air twice over to the human lungs, but to supply them at each fresh inspiration with pure aerial particles in a genial thermometric and hygrometric condition."

Where heating is alone attended to, as in the case of heat conveyed by steam in metal pipes, it becomes necessary to provide currents of cold air, to supply the required continued change in the apartments for the purposes of ventilation. It is manifest, then, that the best principle must be, first, to heat the required volume of fresh air, and then introduce it to the apartments to be heated and ventilated, instead of effecting this double object by two distinct processes. This is effectually accomplished by the plan of Mr. Oldham under consideration. The *modus operandi* is as follows:—A body of pure air, of any required volume, and passing at any required velocity, is forced by the aid of an air-condensing pump into a chamber or chest, where it is heated in an ingeniously-contrived, but extremely simple apparatus, by means of cross currents of steam. The peculiarity of this contrivance is, that an ascending body of air, on entering this chest, divides itself spontaneously into any required number of thin horizontal films, by which a very extended surface is exposed to corresponding steam-heated metal surfaces. Instead, therefore, of passing the steam through a series of pipes, along which, but in an opposite direction, the condensed water has to return, it is conveyed at once from the boiler into the chest or condenser, (which, in fact, it is,) where, on having parted with its heat to the air as above described, it is condensed, and returned directly to the boiler. The chest or condenser, in the apparatus at the Bank of England is but three feet square, yet the body of air to be heated, while passing over but 3 lineal feet, spreads itself over no less than 154 superficial feet, and coming in contact with a corresponding superficies, heated by the steam, it necessarily receives a very large supply of heat in a short space of time.

This apparatus in the Bank of England, independently of heating and ventilating several large apartments, is put to the severest test namely, that of evaporating the moisture from a series of 400 large mill-boards, with a surface of 1600 feet, and which moisture they have absorbed from the fresh-printed bank notes which are daily dried by this process.

With respect to the quantity of heat which this small apparatus is capable of imparting to the air, this is accurately tested by the quantity of water which is condensed, and which amounts hourly to twelve gallons. Now, as Professor Brande observed, when we consider what an enormous body of heat is contained in the steam generated from twelve gallons of water, we are enabled to appreciate the hourly effective heating powers of this apparatus.

As to the volumes of warm air that may be required, that will of course depend on the cubical contents of the buildings to be heated. This, however, may be stated, that there is scarcely any limit, either to the quantity of heat which may be thus given out, or the quantity of fresh air, so heated, that may be propelled by such a system. Of the mechanical means by which this artificial current of air is created, little need be said, these are within the reach of all.

Of the efficacy of an artifical current produced by means of a fan or cylinder, Dr. Ure observes, that "it has been ascertained that a power equivalent to one horse, in a steam engine, will drive at the rate of 80 feet per second a fan, the effective surfaces of whose vanes, and whose inhaling conduits have each an area of 18 inches square, equal to that of a large steam boiler chimney. The velocity of air in the chimney, produced by a consumption of fuel equivalent to the power of twenty horses, was no more than 35 feet per second; while that of the fan, as impelled by the power of one horse, was 66 feet per second. Hence it appears, that the economy of ventilation by the fan, is to that by the chimney draught, as 66 is to $\frac{35}{20}$ or, 38 to 1. It is obvious, therefore, that with one bushel of coals consumed in working a steam-impelled excentric fan, we can obtain as great a degree of ventilation, or we can displace as great a volume of air, as we could with 38 bushels of coals consumed in creating a chimney draft. Economy, cleanliness, and compactness of construction, are not, however, the sole advantages which the mechanical system of ventilation possesses over the physical. It is infallible, even under such vicissitudes of wind and weather, as would essentially obstruct any chimney draught ventilation; because it discharges the air with a momentum quite eddy proof; and it may be increased, diminished or stopped altogether, in the twinkling of an eye, by the mere shifting of a band from one pulley to another. No state of atmosphere without, no humidity of air within, can resist its power. It will impel the air of a crowded room, loaded with the vesicular vapours of perspiration, with equal certainty as the driest and most expansive."

After so clear and practical an exposition of the advantages of a current, mechanically created, nothing further need be said of natural currents arising from mere increase of temperature, excepting that by the adoption of the pump instead of the fan, a very considerable power is saved, and the operation performed much more effectively.

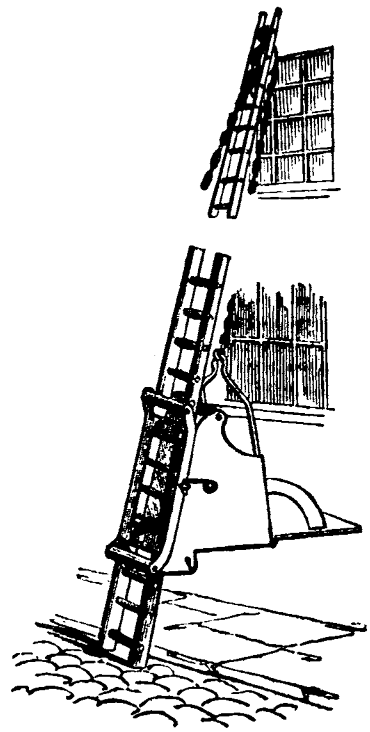
Another peculiarity of Mr. Oldham's apparatus here merits attention. The large volume of air heated and passed off to the required apartments is, previously to its being received into the heating chest, filtered and purified, by being deprived of all that noxious floating matter with which the atmosphere, particularly that of London, is at all times charged, and which, if heated and sent into the apartments with the air, would but increase that noxious character and render it still more injurious to the respiration of human beings. Not only indeed are these offensive impurities which are floating in the atmosphere effectually separated, but a power is given of charging it with aromatic or antiseptic matter, thus rendering it not only the medium of warmth and ventilation, but of purifying and healthful influences.

The peculiarities of Mr. Oldham's arrangements then, are, first, the adoption of mechanical means for the creation of a current of hot or cold air, and which may be augmented to any required extent or volume, instead of that comparatively feeble current which results from the difference of temperature alone; secondly, the causing this artificial current of air to be heated by a peculiar arrangement which separates its volume spontaneously into their horizontal films, thus making them pass in contact with a corresponding number of surfaces heated by steam, imparting a large volume of heat to a large volume of air in a small space and with great rapidity—and when so heated, of again uniting these films—to be passed up in a body in whatever direction or to whatever distance may be required; thirdly, the filtering the air before it is received into the heating apparatus, thus effectually excluding that offensive dust and black matter with which the atmosphere is charged. I am, Sir, &c. C. W. WILLIAMS.

[We will, in our next Journal, if possible, give the drawings of Mr. Oldham's apparatus.—EDITOR.]

MACHINE FOR CLEANING AND REPAIRING FRONTS OF HOUSES, &c., OR A FIRE ESCAPE.

SIR,—As the many melancholy instances of loss of life by fire have occasioned a very general interest in the invention of Fire Escapes, I beg the favour of your notice of one which I think has all the desiderata mentioned by Captain Manby, in his address to the Society for the Protection of Life from Fire, namely, simplicity, portability, and efficiency. I may add to these, economy in construction as being not a whit less important, seeing that the cheaper such machines can be made the greater will be the chance of their being kept in every part of the metropolis; the expense of mine will not exceed seven pounds; and in quantities, I have no doubt they may be made for a third less.



As I do not pretend to be more than an amateur in mechanics, I fear I shall very ill explain myself. By reference to the annexed sketch it will be seen that my invention consists of a car traversing up and down the inner or under side of a ladder, which it uses as a sort of inclined railway, and is suspended to the top round of the ladder by means of a chain passing over a pulley of a snatch block. The car may be adjusted to any sized ladder, which is admitted within the double framework of the machine between four rollers (two at the top and two at the bottom), each of which have occasionally a bearing on the ladder, but generally only the lowest inside and the upper outside rollers. The car weighs, including a single fall rope and block, about 90lbs, and I propose that every fire engine should carry one, which may be attached very ornamentally at the opposite end to the driving box.

By means of this car a fireman could be raised to the upper windows of a house without difficulty by three persons, and thus afford personal help to those in danger, who, nine times in ten, have not presence of mind to avail themselves of the aid thrown up from below.

As the car descends with the inclination of the ladder, it of course recedes from the front of the house; it is, however, enabled to put forth in case of need an additional projection or stage of four feet, as shown in the sketch, which I believe would be the utmost required. Such a machine will also be found very useful for builders, plasterers, painters, and others, for the purpose of repairing, cleaning, colouring, or painting fronts of buildings. If generally adopted for such purposes, hardly a street would be without one, which would form an additional certainty of the fire-escape being ready in case of need.

I need not be reminded that my invention is nothing without a ladder; but as fires very rarely happen without their being speedily procured in the neighbourhood, there cannot be any difficulty on that point.

Hoping to obtain, through your widely circulated publication, some practical opinion of the machine, I intrude this communication.

And remain, Sir, yours, &c.,

Nine Elms, December 31, 1838. A. F.

THE NATIONAL GALLERY.

SIR,—I had been for some time coveting a little leisure to submit a few opinions to you on this ill-fated building, when the "Supplement to the Public Buildings of London," by Mr. Leeds, informed me that my intentions were anticipated by one much more competent to speak upon the subject. The points to which I more immediately intended to advert, were for the most part those on which Mr. Leeds has so forcibly commented, viz., the absurdity of accusing the architect of having *diminished* the capacity of the building by the very measures which, on the contrary, *increased* it (see pages 62, 63); the inconsiderate outcry concerning its being "too low" see pages 67, 68); and the injustice of "censuring in the lump, without caring to hint at particular beauties in what upon the whole may be defective."

It is not for me to presume that anything emanating from so humble a correspondent as myself, will be allowed to add much weight to the criticism of Mr. Leeds; nor should I venture on these remarks, but that opinions—and very decided ones—have been expressed by so many persons, whose right to pass sentence is not more than mine.

The defects of the structure should have been criticised with a more candid reference to the imperative necessities which interfered with the full exercise of the architect's taste; and the merits of the portico (particularly as regards its plan) of the entrance hall, and of the general proportions of the several compartments of the facade, separately considered, should have been allowed. Granted, the central cupola is small, its tambour much too plain, and the two smaller cupolas or turrets unnecessary. The cornice of the portico, too, certainly lacks that prominence and richness which the Corinthian columns (particularly as they are fluted) require; but the portico otherwise, in regard to its low-pitched pediment (perhaps it may be too low) and the just approximation of its columns, is worthy of infinitely more admiration than the St. Martinians have yet bestowed upon it; and I cordially agree with the writer, whose minute analysis would render any further comments gratuitous, that the "facade, if erected some years earlier, would have been probably as much extolled as it has now been decried."

My chief purpose in now addressing you, is to suggest such remedial measures as I conceive to be—at a very little expense—practicable; and I therefore, with all deference (as to an unquestionable superior whom, in spite of the world, I delight to honour) submit to the architect the adjoined sketch, simply showing how, by raising attic stories over the central and extreme compartments; by transposing the columns now in the centre of the wings, and by placing a pilaster attic order round the tambour of the dome, an altered effect would be produced, which the public might deem an improvement. The dome will still perhaps remain too small (the dotted line inclosing it being more accordant with my own notions of proportion), but it will certainly not be so objectionable on the score of plainness. If the dome could be entirely reconstructed, it might possibly be made at once available, for increased accommodation and effect; but I am speculating only on what may be gathered from the small engravings before me, and saw too little of the building when in London some time back, to venture on anything more than mere suggestions.

Your obedient servant,
GEORGE WIGHTWICK.

Plymouth, Feb., 1839.

[We regret that it is out of our power to comply with the request of our correspondent as to the insertion of a wood-cut, as it would form a precedent which would not fail in other cases of suggestions to entail on us great inconvenience and expense. We think his proposed alterations would be calculated to produce the effect he describes, but they would have a tendency to alter the character of the building from its present classicality.]—*Edit. Civ. Eng. & Arch. Journal.*

RAILWAY CURVES.

Sir,—Having been lately employed setting out railway curves, like your correspondent, "A Sub" (in your January number), I cannot help offering a few observations on his plan; although I fear I am not one of the "more experienced readers" that he expected would take it up. He says, he thinks "it would be an improvement upon the system of running directly from a straight line to a curve of $1\frac{1}{2}$, 2, or $2\frac{1}{2}$ miles radius, if a curve of 3, 4, or 5 miles radius, for a short distance, were made use of to connect them."

Now to me it appears that the true principle is this:—When you must change your line of direction in a railroad, do so with as *equable* a curvature as possible; for we know that if the curvature is not equable, some parts of it must be sharper than if the same radius were used all through. This, I think, would be a sufficient reason for rejecting his plan at the outset.

But even if without injury we could have a gradual increase of curvature—*Cui bono?* Is it to *accustom* the engines to a curvilinear path? Surely when an engine is at a point just entering on a curve, it is pretty clear that its *action* on that curve will not be affected by the nature of the path it was *previously* describing, since its tendency just then is in the direction of the tangent, which is quite independent of that path.

Again, your correspondent says, "that projectiles (where the resistance is equal) assume the parabolic curve," by which he proposes an approximation. Now the *resistance being constant* is not the cause of a projectile's describing a parabola, but because gravity, which acts upon it, is a constant *force*, producing a constantly *accelerated* velocity, so that the distances gone in a vertical direction are as the squares of those gone in a horizontal (counting from the highest point), which *is not* a very similar case to that of an engine moving along a railway. But even if we were to draw an inference from the motion of a projectile, I would do it thus:—We know that the curvature of its path is not constant, neither is its velocity—the latter being least when the former is greatest; now, the velocity of an engine *should* be constant, if possible—therefore, let the curvature of its path be so also.—I remain, Sir, your most obedient servant,

Feb. 19, 1839. B. W. T.

A METHOD FOR STRIKING GOTHIC ARCHES.

Sir,—I beg leave to make public, through the medium of your Journal, the following method, which I discovered some years ago, and which I believe to be original, for Striking Gothic Arches, more particularly that which has been termed the Tudor arch:—

Having determined the height and breadth of the arch, draw a horizontal line on a whitened wall; make the length of this line twice the height of the arch, and from the centre of the line, let fall a perpendicular, to which give one half the width of the arch. Let nails be driven at the two extremities of the horizontal line; to one of these fix an end of a chain somewhat heavy, but composed of short links, and, passing the other end over the other nail, draw up the chain till the bottom of the curve correspond with the extremity of the perpendicular, and when in that position make the chain fast to the nail over which it was passed. This done, trace upon the wall, with charcoal or otherwise, one half of the curve formed by the freely suspended chain. This curve, placed in such a manner as that the lower or more curved part may rest upon the impost, will form one half of the required Tudor arch, the other half being its counterpart—thus:—

Fig. 1.

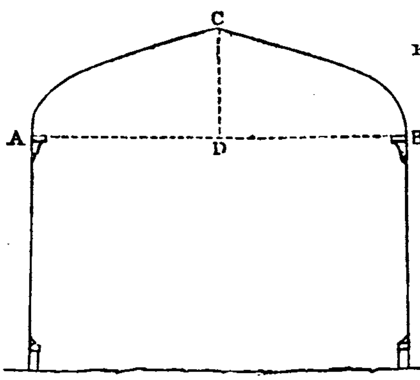


Fig. 2.

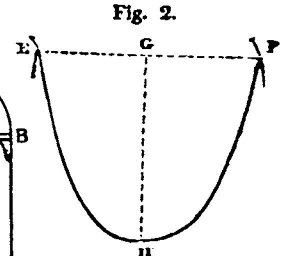

Let A B (in fig 1) be the breadth of the required arch, and C D its height. Set off on the wall (fig 2) E F=2 C D; from the centre G, of E F, let fall $G = H\frac{AB}{2}$. The chain being fastened at E, and then passed over F, and drawn up until the bottom of the curve correspond with H, make fast at F. Now the curve E H or F H placed so as that the more curved part fall on the impost; and the extreme E or F at the point C (fig 1), will be half of the required Tudor arch. By this bisection and arrangement of a Catenary, gothic arches of various agreeable curvature may be most easily and expeditiously traced.

I am, Sir, your most obedient,

13th Feb. 1839. J. R. JACKSON, Col.

[We have taken the liberty of altering our correspondent's arrangement of the figures, by making two answer the purpose of three, which we hope he will excuse, particularly as it does not interfere with the description of his ingenious and simple method of setting out the arch; a method which, we are sure, will be appreciated by the profession.—Editor.]

MONTROSE WET DOCK.

Report of James Walker, Esq., Civil Engineer.

The Site.—Having visited Montrose, in company with Mr. Leslie, early in December last, I surveyed the sites and plans of Docks proposed by that engineer, viz.,—the Horologe Hill site, and the other between Meridian Place and the patent Slip, or farther down the river than the Horologe Hill; and I have no hesitation in preferring the lower situation. It places the entrance in a wider and better part of the river, where the eddy-tide will render the entering of the ships very easy; it interferes less with the present wharfage; and (which I think very important) gives the opportunity of extending the Docks as occasion may require upon the links—a property which is uncovered and belongs to the town. I consider this site also, whether as respects approach from sea, entrance to the Dock, or the Dock itself, peculiarly eligible.

First, as to the Approach from Sea.—Having had reference to an apparently very accurate survey by Mr. Buchanan of Edinburgh, and having been favoured by Captain Beaufort with the Admiralty survey of the harbour, a copy of which is now before me, I find the depth between the Annat Sand and the Leads, at low water of spring-tides, from seventeen to eighteen feet, which was confirmed by the sounding I took: outside of this to deep water, there is nothing less than fifteen feet; inwards, the depth decreases gradually to less than half the above,* until opposite the Low Light, when it again increases to 13, 12, 14, 16, 10, and 11 feet, which last is in the Stell, opposite to, and not far from the entrance to the proposed lower Dock. Four feet may be added to all the above depths for the low water of neap-tides; thirteen feet for the high water of neap-tides; and eighteen feet for the high water of spring-tides. The length from the entrance to the harbour to that proposed for the Dock, is upwards of a mile, nearly straight, with rocky ground on the south bank, and sand on the north; but no rocks in the channel of the river: the bearing being N.W. by W. ½ W., and the width in the Stell, opposite to the proposed entrance to the Dock, about 300 yards. In this place, the direction of the flood-tide is thrown over towards the south side, so that for about a width of 100 yards from the shore, there is scarcely any current. The passage from sea, therefore, up to the Dock entrance, may be pronounced decidedly good.

Secondly, as to the Entrance.—Mr. Leslie has pointed the entrance down the river, which, had there been any current to interfere with ships entering, would have been objectionable; but in the present case, it is, for the reasons above stated, a matter of comparative indifference. This entrance is proposed to be fifty-five feet in width, and fifteen feet six inches in depth, at the high-water of neap-tides, which I think sufficient, and was so considered by the trustees when the subject was mentioned at the meeting. Mr. Leslie proposes one pair of gates at first, and shows by dotted lines upon the general plan, how this extension may be made at any future period into the river, so as to form the entrance into a lock with two pair of gates. This is the part of the design, the idea of which, for the reason I shall presently state, ought, I think, to be abandoned. The Dock is to be of the same depth as the entrance; the form a rectangular parallelogram, four hundred and fifty feet long, and three hundred feet broad,—giving an area of three acres, which, for a Dock, I consider decidedly too small; and that the plan would therefore be objectionable, were it not for the great facility of extension upon the links,—my opinion being that, in a very few years, the three acre Dock will not be too large for a tide basin, with one pair of gates into the river, to be opened before high-water; and that then the lock with the double gates should be at the upper end of the basin, to lock out of it, up to the inner Dock or Docks, properly so called, which may then be of a size thought expedient; for what would, in respect of size, be considered extravagant if recommended now, will not probably appear so when the first Dock, which will afterwards be the basin, shall be found insufficient. The sketch which accompanies this report will better explain my meaning. I would not recommend more being done at first towards the ulterior plan than simply returning the wing walls to form the future entrance, and making the front of the Dock or basin wall between these returns of timber piles or baulks to form a dam for future works within, and to be removed when these works shall be completed. With the above modification, I entirely approve of Mr. Leslie's plan, the execution of which does not appear to me to present any peculiar difficulty which Mr. Leslie has not provided for.

Water.—What was said to me of the apprehension that there would be great difficulty in keeping the works clear of water, led me to inquire particularly respecting the wells that had been dug in the neighbourhood, and the nature of the strata. On these points, I had information also from Charles Gordon, an experienced well-digger, as well as from Mr. Leslie, and other gentlemen. There will be water undoubtedly, as the ground is sand and gravel, with silth below: this will have to be pumped out, and the springs and wells round will be drained; but, after this is done, the water will diminish, and the quick-sand lose its quickness. I feel assured, from experience in similar cases, that a moderate-sized pumping engine will overcome the difficulty of water. The docks in the Thames are made in sand and gravel, under a clay surface: the Hull docks are all in silth. Mr. Leslie having furnished me with a copy of his working-plans, I have examined the same, and find that great pains have been taken with them: they are very particular and explanatory. I have also examined the estimate in detail, by taking out the quantities from the plans, and find that the same care has been extended to this. The sufficiency of the prices in some cases, particularly the masonry, may be tested by those who have local information. From the proximity to quarries, I think them sufficient; but that the prices of the dams and the excavation are close, considering the contingencies to which these works are liable. On the whole, I would recommend an addition of 3,000*l.* to the amount of 35,121*l.* upon the works detailed in the estimate. On examining the detail, I do not find the following particulars to be included, viz.:—The Dock-gates, mooring and warping buoys in the river, moorings or bollards in Dock, pumping (with the steam-engine) while the works are in progress. These will amount to 4,000*l.*, making an addition of 7,000*l.* to the estimate of 35,121*l.*†

* The Admiralty survey makes six feet only upon the Cross Dykes, the shoalest place, which must be a very low tide.

† Mr. Leslie prepared two estimates; the one being the parliamentary estimate, comprehending the whole work, and amounting to about 40,000*l.*; the other was got by the Trustees, in October, 1837, along with working plans and specifications for the work, exclusive of Dock gates, in four departments, and amounted to 35,000*l.* odds. This last estimate, Mr. Leslie has explained, did include the expense of pumping with the engine, but did not comprehend the Dock gates, stated in the parliamentary estimate at 3,000*l.* Mr. Leslie did not view moorings a part of the Dock, properly so called. The working plans, specifications, and estimate, got in October, 1837, were those submitted to Mr. Walker.

The Harbour.—The Harbour is intimately connected with the Docks; and, as my attention was called, and several questions asked, at your meeting, on the various points relative to the former, it cannot be considered irrelevant if I repeat what I then stated. I have already referred to the principal features of the entrance and river up to the Stell. The harbour is considered by you, and probably with reason, as the best between the Forth and Murray Firth: it is therefore very important in a public view, although certainly not a perfect harbour of refuge; for, with north-east winds, the Leads stone, and other rocks, are upon the lee, close to the entrance, and nearly dry at low water; and, with south-east gales, ships are stated to lie uneasy in the Stell; yet, with westerly, which are the prevailing winds, the harbour affords good refuge. The number of wind-bound vessels that entered the harbour last year was sixty-four; and it was stated to me that twenty to thirty were in the harbour at the same time. Considering the harbour thus, even in a public light, a good beacon should be placed at the entrance, upon the dangerous rock to which I have before alluded; and, judging from my experience in this quarter, I think it more than probable that, if a proper representation were made to the Commissioners of Northern Lights, they would either undertake the work, or assist in it.

The Basin.—As the harbour of Montrose may be considered the passage through which the sea-water finds its way into the Basin* when the tide is at flood, and out of it when the tide is at ebb, and as its depth and width are proportioned to the quantity of water that passes, so every thing that diminishes that quantity, or lessens the basin, has the direct effect of lessening the width and depth of the harbour. Therefore, the basin, to the extent that is covered by a spring tide, should be watched with jealousy, and every encroachment prevented. In the Admiralty survey, it is included as part of the harbour; it is part of the plan now before me, and every encroachment upon it may, by a special Act of Parliament, be the subject of prosecution; but your interests are more immediately concerned, and you have a better opportunity of guarding this, which may be considered the lungs of your harbour.

Harbour Trust.—A meeting of the trustees of the harbour took place in the Town-Hall, on Monday, 28th January last, Provost Crawford in the chair, when the clerk laid on the table the above report. The meeting were highly gratified with the tenor of the report, and concurred in a unanimous opinion, "that the authority of so eminent an engineer as Mr. Walker, in corroboration of Mr. Leslie's views, completely removes all objections to the plan, in regard to site, foundations, eligibility, or otherwise,—and also justifies the trustees in concluding that the works can be executed for a sum below the amount warranted by the rates leviable under the Act, which afford the most adequate security to lenders." The provost then stated that several gentlemen interested in the improvement had resolved to advance 15,000*l.* to the trustees, or to give their guarantee to that amount; and that he was appointed to announce this to the meeting. The trustees expressed their hearty approbation of the proposed loan or guarantee, and agreed to accept of the same, and to record their thanks to the gentlemen who had come so liberally forward to promote the undertaking. The meeting afterwards appointed committees for arranging and disposing of sundry matters preliminary to the commencement of the work, which will be contracted for without loss of time. We understand that the outer wall of the Dock, which is 600 feet in length, and will consequently be of some temporary service to the shipping, is to be first completed.—*Montrose Review.*

HISTORY OF PAPERHANGINGS.

Extracts from a paper by Mr. CRACE, read before the Royal Institute of British Architects.

Paperhangings are of comparatively modern origin, and although they are of such consequence both from the present extent of the manufacture, and as a vehicle for the diffusion of taste, I believe that there has never yet been written any detailed account of its rise and progress in this, or as far as I can discover, in any other country. I imagine them to have been originally manufactured as a cheap imitation of the rich stuffs and tapestries used by our ancestors to cover the stone walls and wainscoting of their apartments.

The English and Flemish were the first in Europe who excelled in tapestry, and are supposed to have brought the art from the Crusades; the workmen in France, from this cause, were called Sarozins.

The well known Bayeux tapestry, representing the invasion of this country by William the Conqueror, is supposed to be the oldest existing specimen. Turner, the historian, says, that our Anglo-Saxon ancestors had wall hangings, some silken, some with figures of golden birds in needlework, others woven, and some plain; and in various illuminated manuscripts dating from the 14th to the 16th centuries, I have found this material frequently introduced as a covering for the walls, and particularly as a canopy for thrones and chairs of state.

It is in the reign of Henry the Eighth that I have been first able to trace the distinct manufacture of the wove tapestry; and Dugdale, in his Warwickshire, affirms that it was *now first* introduced into England by William Sheldon, Esq., who brought over workmen from Flanders about 1540, and employed them in drawing hangings, of which I believe specimens still remain at Weston. Notwithstanding the authority of Dugdale, I think the art was merely then revived; for Lord Arundel, by his will in 1392, tempore Richard the Second, bequeaths to his wife Philippa the hangings of his hall *recently* made in London; and even ten years previously Richard

* In the Admiralty survey the Basin is called the Slake.

the Second granted a licence to Cosmo Gentilis of six pieces of tapestry, of a green ground, powdered with roses, which the king sent as a present to the Pope. However, the art seems in the reign of Henry the Eighth to have been brought to a perfection it had not before attained, and the great Holbein is supposed to have furnished various designs for it.

About this time the use of tapestries was not confined to the nobility, but it was not uncommon to see abundance of arras, rich hangings of tapestry, silver vessels, &c. in the houses of persons of much meaner quality.

In the reign of James the First, a very extensive manufactory of hose tapestry was established at Mortlake, in Surrey, by Sir Francis Crane, which was munificently patronised by that king and his son Charles the First, who granted an annuity of £2000 towards the maintenance of the undertaking. Francis Cleyn, a painter of considerable reputation in the service of the king of Denmark, recommended by Sir Henry Wotton, was employed in this manufactory, and gave designs in both history and grotesque. Indeed, the beautiful hangings which then adorned the British palaces were much admired by foreigners of distinction, who visited this country, and the manufacture was held in high repute abroad. The civil wars, however, ruined this large manufactory to which I have just alluded, and it does not appear to have been again carried on to any extent.

A Monsieur Pariport, in 1720, made a spirited attempt to compete with the celebrated Gobelins at Paris, and founded a considerable manufactory at Fulham, in which he was nobly encouraged by the then Duke of Cumberland, who assisted him with a gift of £6000, but this soon failed; and in 1759 a set of designs for tapestry, painted by Zucharelli, and executed by Paul Saunders for the Earl of Egremont, for a house he built in Piccadilly, were the last made in this country.

Connected with tapestry are the silk and satin damasks and the rich figured velvets; and another material much employed in this country for hangings and other purposes was the stamped and painted gilt leather, on which was represented sometimes in relief divers kinds of grotesques, relieved with gold and silver, vermilion and other colours. Many suppose it to have been invented by the Spaniards, and by them communicated to the Flemings, who excelled in it, and introduced here about the time of Henry the Eighth.

The writers in the French Encyclopedia confess, even in 1762, that though the stamped leather of France equalled that from Flanders and Holland, yet that that made in Venice and England was superior in both beauty of design and durability. This manufacture so much resembles that of paperhangings, that I conclude it must have given the idea for the invention of, at any rate, one branch of the subject now under consideration.

Paper hangings may be divided into three separate branches; the flock, the metal, and the coloured; and each of these seems to have been invented at a different time, as an imitation of a distinct material—the flock to imitate the tapestries and figured velvets, the metal in imitation of the gilt leather, and the coloured as a cheap substitute for painted decorations. Professor Beckman says, that the former of these, the flock, was first manufactured in England, and invented by Jerome Langer, who carried on the art in London, in the reign of Charles the First, and obtained a patent for his discovery, dated May 1st, 1634. Various French and German authors give us the credit of this invention, yet it is disputed by a Frenchman, M. Tierce, who in the Journal Æconomique says, that a man named François carried on this art at Rouen so early as the year 1620 and 1630, and affirms that the wooden blocks employed are still preserved with the before-mentioned dates inscribed on them. François was succeeded by his son, who followed the business with success for fifty years, and died at Rouen in 1748 (?) M. Savary, in his Dictionnaire de Commerce, thus describes the manner in which the French manufactured their tonture de laine, or flock hangings:—The artist having prepared his design, drew on the cloth, with a fat oil or varnish, the subject intended to be represented; and then the flocker, from a tray containing the different tints of flocks, arranged in divisions, took the colours he required, and sprinkled them in a peculiar manner with his finger and thumb, so that the various shadow ands colours were properly blended, and an imitation of the wove tapestry produced.

Of the second branch, the metal papers, I do not find much mentioned by the older writers; and of the coloured papers, I almost despaired of finding any early account, till, in an old French dictionary of commerce, printed in 1723, under the head of Dominoterie, I discovered an account which seems to give the origin of the present system of paperstaining. Dominoterie is an ancient French name for marble paper, such as used by bookbinders; and the early French paperstainers were associated with the makers of that article, as a class called Dominotiers. The manufacture is thus described:—

The design having been drawn in outline, on paper pasted together of the size required, the paper was then divided into parts of a suitable size, and given to the carver or wood engraver, to cut the designs on blocks of pear tree, much in the same manner as at present. The outline thus cut was printed in ink with a press, resembling that then used by the letterpress printers, on separate sheets of paper. When dry, they were then painted and relieved with different colours in *distemper*, and afterwards joined together, so as to form the required design. The author then adds, that grotesques and panels in which are intermingled flowers, fruits, animals, and small figures, have up to this time succeeded better than imitations of landscapes, or other tapestry hangings, which are sometimes attempted, and refers to article 61 of the French laws in 1686, which confirms the statutes published in 1586, 1618, and 1649, in which rules are given as to what kind of presses, &c., are to be used by the dominotiers, and prohibiting them under heavy penalties from printing with types.

Recurring to the subject as connected with this country; in the year 1754, a Mr. Jackson, a manufacturer of paperhangings at Battersea, published a work on the invention of printing in Chiaro Oscuro, and the application of it to the making of paperhangings, illustrated with prints in proper colours. This book is a sort of advertisement of the kinds of papers made, and the mode of manufacture employed by him. He adopted a style of paper hangings executed with blocks in Chiaro Oscuro, in imitation of the most celebrated classic subjects.

To use his words, "The person who cannot purchase the statues themselves, may have these prints in their places, and thus effectually show his taste. 'Tis the choice and not the price which discovers the true taste of the possessor; and thus the Apollo Belvedere, the Medicean Venus, or the Dying Gladiator, may be disposed of in niches, or surrounded with a mosaic work in imitation of frames, or with festoons and garlands of flowers, with great taste and elegance; or, if preferred, landscapes after the most famous masters, may be introduced into the paper. That it need not be mentioned to any person of taste how much this way of finishing with colours, softening into one another with harmony and repose, exceeds every other kind of paperhanging hitherto known, though it has none of the gay, glaring colours in patches of red, green, yellow, and blue, &c. which are to pass for flowers and other objects in the common papers."

By the account of this gentleman we find that paperhangings were then in common use, and had reached a certain degree of perfection, for that even arabesques were executed; and I therefore conceive that the art discovered by Lanyer had been continued from his time to the present; particularly as in the year 1712, the 10th of Queen Anne, a duty of 1½d. per square yard is imposed on this manufacture. In the reign of that queen the Chinese paperhangings were very much employed, and have continued in fashion to the present day. These hangings, though parts of them may be executed by blocks or stencils, are almost wholly painted by hand. Cotemporary with Jackson, I have learned that a Mr. Taylor, the grandfather of one of our present most eminent manufacturers, carried on this business to a considerable extent, and accumulated a large fortune. He was succeeded by his son, who, I am informed, visited France, and was enabled to give the manufacturers there considerable information. He said, on his return, that he found the French paperhangings very inferior to our own, both as to execution and beauty of design. In those days we had an extensive export trade in this material to America and other foreign parts, but we are now driven out of this market by the French. The paperhangings at that date, about 1770, were manufactured nearly in the same manner as at present; I have indeed seen a flock paper of a large rich damask pattern, more than 100 years old, which resembles in every way the modern material; it is singular that this art of flocking was disused and almost lost during a period of twenty years, and revived only about forty years ago; a mode of decorating papers was also formerly employed, which is now never adopted. I have seen papers ornamented with a substance commonly called frost, a species of talc.

In the year 1786 there was established at Chelsea a manufactory for paperhangings of a superior description, conducted by Messrs. George and Frederick Echardts, gentlemen of considerable taste and spirit. The mode of manufacture was different to that in general use; for, besides the usual printing blocks, copper plates, on which were engraved designs of great finish and beauty, were likewise employed, and they not only printed on paper but also on silk and linen; and by an underground of silver or gold, they obtained very beautiful effects of colour.

Only part of the design was given by printing; it was finished by artists constantly retained by the manufacturers, men of considerable talent, who again were assisted in the inferior parts by young girls, of whom more than fifty were employed; and had this undertaking been supported by the government, it would, I do think, have been more available as a school for our rising artists, and of infinitely greater service than our present school of design, for it would have been a *working school*, and no other, I am convinced, will be of any use in forming a talented race of decorative artists in this country. There was also about this time another establishment similar to the former, conducted by Mr. Sheringham, in Marlborough-street.

From this time the French began to excel in this superior branch of the art, which with us had fallen on such barren ground. Their manufacturers were encouraged in every way by their government and the Emperor Napoleon, to attempt that perfection which they have now so successfully attained.

Having now slightly sketched the history of this art up to the present time, I propose on some future occasion, if agreeable to the society, to explain to the best of my power the different processes employed in the manufacture.

[The continuation of this interesting paper, which was read at a subsequent meeting, we shall publish in the next Journal.]

DESCRIPTION OF THE PATENT CEMENT OF MR. R. MARTIN, OF DERBY,

Read at the Royal Institute of British Architects, February 18, 1839.

The composition of my cement consists of a solution of pearlash and sulphuric acid, mixed to the exact point of neutralization with powder of gypsum, and the whole calcined together.

In calcination every particle of crystallized water and native acid is driven from the gypsum, and their place supplied with the alkali and acid made sulphate of potash as above described.

This change of solidifying substances creates properties altogether new and opposite in effect to all other water-mixed cements. There is neither heat nor expansion in solidification, nor subsequent swelling from absorption of the atmosphere or by immersion in water. It therefore results that the cement neither cracks nor creases, when used either as an in or out-door stucco. The mode of using the cement is very simple—similar to common lime plaster, but the purposes to which it is applicable are extremely varied. As it can be made of a variety of colours in manufacture, or colours introduced, it will supersede the necessity of paint or paper, where their use is objectionable; it is therefore particularly applicable for attics and basements.

For imitations of marble it must become the substitute of plaster of Paris, it being much more dense, and through its nonabsorptive quality withstanding all atmospheres, as has been already proved. As it does not expand in solidification, as above stated, solid figures may be cast with it if pressed into moulds. It combines readily with limes slaked or quick, and mixed with the latter it prevents its slaking, and with these, or by itself and sand, it forms an excessively hard and durable stucco. In its prepared state for use it does not receive the slightest injury from exposure to a damp atmosphere for any length of period, and will therefore carry without depreciation to any part of the globe—it is effective for every purpose for which the limes of this kingdom are used in its transatlantic possessions; and from being double their weight, will be nearly as economical in use, independent of its peculiar properties excluding all moisture and preventing the intrusion and ravages of insect and other vermin: considerations not only important to the resident, but to the government as conservators of the public stores.

For the joining together of stones, bricks, &c., it has not its equal, and can be used with the greatest advantage, where lime proves but an insufficient bond, and Roman cement from its expansive properties is improper; say for light-houses and other very elevated and much-exposed structures.

Applied as a stucco over common lime plaster a very smooth and hard surface is produced, and is so little absorbent that in painting two coats are sufficient. This application was made by Mr. Chadwick above three years since, on two halls at Adelaide-place, London Bridge, and who will verify the fact here stated.

In the summer of 1837 it was applied in castings and as a stucco, at 72, Cheapside (opposite the Atlas Insurance Office); the stucco has been since painted over, but not so the two coats of arms, which, as well as the stucco, have withstood the two last winters without the slightest injury.

Any further information respecting properties, &c., &c., may be obtained of Mr. Bernasconi, Alfred-place, Bedford-square, and who will also show specimens of its various applications.

PHOTOGENY;

OR, THE ART OF FIXING THE IMAGES OF VISUAL OBJECTS.

The means of obtaining a self-acting, permanent representation of visual objects, has long attracted the attention of philosophers, and in 1802 was the subject of experiments by Wedgewood and Sir Humphry Davy. Their efforts, further than recognising the sensibility of nitrate of silver, were, however, ineffective, as were those of a committee of the Academy of Sciences, composed of Laplace, Malus, and Arago, who were engaged in a similar manner investigation for ascertaining the power of moonlight. Chlorure of silver was also known to be easily acted upon by the rays of light; but it was not until the close of last year that any announcement was made of the progress of this art. Mr. Fox Talbot seems to have been first in the field; but M. Daguerre, the inventor of the diorama, made the first disclosure. As the two processes seem to be distinct in their results, we shall give a description of each separately, as derived from the "Compte Rendu" of the Academy of Sciences, and from the letters of Mr. Talbot. To commence with that of M. Daguerre, it is effected by placing a copper plate in a camera obscura, which copper plate being covered with a chemical preparation susceptible of the effects of light, produces a shaded drawing on the plate. These designs, when finished, may be exposed to the glare of the sun without changing, and will bear the scrutiny of a microscope. On reverting to the different powers of colours, it can be readily conceived that the several tints and shades will produce an effect corresponding to their intensity; the three primitive colours, as determined by Field, standing in the relation of three, five, and eight; the time required for the process varies with the quantity of light, and, consequently, with the season and time of day; in summer, at noon, eight or ten minutes is sufficient. This apparatus is at present incompetent to the representation of moving objects, and is imperfect even with regard to trees. A hackney-coach stopped during the drawing of one of the scenes, and one of the horses, turning his head during the process, is represented without one. A shoe-black, also engaged in his vocation, appears without arms; The Academy of Sciences expressed a unanimous opinion of the utility and importance of this invention, and application has been made to the French Government to remunerate the inventor. The announcement of this discovery led to the declaration of Mr. Fox Talbot, who has perfected another variety of the same process. He uses a prepared paper, and produces a representation in coloured tints, which, after the drawing is finished, is not affected by sunshine. Both processes possess peculiar advantages, and have a superiority over any chemical medium heretofore known. Chlorure of silver being white, is blackened by the light, and the white parts of the image become black, whilst the black parts remain white. Nitrate and muriate of silver obtain an impression in half a second, but none of these preparations produce a permanent effect. The importance of the new discoveries will open a new world to science, and even by the results already produced, the bounds of human investigation have been enlarged. The preparation of M. Daguerre is so sensible that it has obtained an image of the moon in twenty minutes, although the light of that body is 300,000 times less than that of the sun, and it produces no effect on any other chemical substance yet known. M. Daguerre is also said to have obtained an impression from the star Sirius, thus proving the fixed stars to be suns, and that light is homogeneous throughout the universe.

We copy the following very interesting account of the process of Mr. Talbot from our respectable contemporary, the "Athenæum":

1. In the spring of 1834 I began to put in practice a method which I had devised some time previously, for employing to purposes of utility the very curious property which has been long known to chemists to be possessed by the nitrate of silver; namely, its discolouration when exposed to the violet ray of light. This property appeared to me to be, perhaps, capable of useful application in the following manner:—

I proposed to spread on a sheet of paper a sufficient quantity of the nitrate of silver, and then to set the paper in the sunshine, having first placed before it some object casting a well-defined shadow. The light, acting on the rest of the paper, would naturally blacken it, while the parts in shadow would retain their whiteness. Thus I expected that a kind of image or picture would be produced, resembling to a certain degree the object from which it was derived. I expected, however, also, that it would be necessary to preserve such images in a portfolio, and to view them only by candle-light; because, if by day-light, the same natural process which formed the images would destroy them, by blackening the rest of the paper.

Such was my leading idea before it was enlarged and corrected by experience. It was not until some time after, and when I was in possession of several novel and curious results, that I thought of inquiring whether this process had been ever proposed or attempted before? I found that in fact it had; but apparently not followed up to any extent, or with much perseverance. The few notices that I have been able to meet with are vague and unsatisfactory, merely stating that such a method exists of obtaining the outline of an object, but going into no details respecting the best and most advantageous manner of proceeding.

The only definite account of the matter which I have been able to meet with, is contained in the first volume of the "Journal of the Royal Institution," page 170, from which it appears that the idea was originally started by Mr. Wedgwood, and a numerous series of experiments made both by him and Sir Humphry Davy, which, however, ended in failure. I will take the liberty of quoting a few passages from this memoir.

"The copy of a painting, immediately after being taken, must be kept in an obscure place. It may, indeed, be examined in the shade, but in this case the exposure should be only for a few minutes. No attempts that have been made to prevent the uncoloured parts from being acted upon by light have as yet been successful. They have been covered with a thin coating of fine varnish; but this has not destroyed their susceptibility of becoming coloured. When the solar rays are passed through a print, and thrown upon prepared paper, the unshaded parts are slowly copied; but the lights transmitted by the shaded parts are seldom so definite as to form a distinct resemblance of them by producing different intensities of colour.

"The images formed by means of a *camera obscura* have been found too faint to produce in any moderate time an effect upon the nitrate of silver. To copy these images was the first object of Mr. Wedgwood, but all his numerous experiments proved unsuccessful."

These are the observations of Sir Humphry Davy. I have been informed by a scientific friend that this unfavourable result of Mr. Wedgwood's and Sir Humphry Davy's experiments was the chief cause which discouraged him from following up with perseverance the idea which he had also entertained of fixing the beautiful images of the *camera obscura*. And, no doubt, when so distinguished an experimenter as Sir Humphry Davy announced "that all experiments had proved unsuccessful," such a statement was calculated materially to discourage further inquiry. The circumstance, also, announced by Davy, that the paper on which these images were depicted was liable to become entirely dark, and that nothing hitherto tried would prevent it, would perhaps have induced me to consider the attempt as hopeless, if I had not (fortunately), before I read it, already discovered a method of overcoming this difficulty, and of *fixing* the image in such a manner that it is no more liable to injury or destruction.

In the course of my experiments directed to that end, I have been astonished at the variety of effects which I have found produced by a very limited number of different processes when combined in various ways; and also at the length of time which sometimes elapses before the full effect of these manifests itself with certainty. For I have found that images formed in this manner, which have appeared in good preservation at the end of twelve months from their formation, have, nevertheless, somewhat altered during the second year. This circumstance, added to the fact that the first attempts which I made became indistinct in process of time (the paper growing wholly dark), induced me to watch the progress of the change during some considerable time, as I thought that perhaps *all* these images would *ultimately* be found to fade away. I found, however, to my satisfaction, that this was not the case; and, having now kept a number of these drawings during nearly five years without their suffering any deterioration, I think myself authorised to draw conclusions from my experiments with more certainty.

2. *Effect and Appearance of these Images.*—The images obtained in this manner are themselves white, but the ground upon which they display themselves is variously and pleasingly coloured.

Such is the variety of which the process is capable, that by merely varying the proportions, and some trifling details of manipulation, any of the following colours are readily attainable:—Sky-blue, yellow, rose-colour, brown of various shades, and black. Green alone is absent from the list, with the exception of a dark shade of it, approaching to black. The blue-coloured variety has a very pleasing effect, somewhat like that produced by the Wedgwood-ware, which has white figures on a blue ground. This variety also retains its colours perfectly if preserved in a portfolio, and not being subject to any spontaneous change requires no preserving process. These different shades of colour are, of course, so many different chemical compounds, which chemists have not hitherto distinctly noticed.

3. *First Applications of this Process.*—The first kind of objects which I attempted to copy by this process were flowers and leaves, either fresh, or selected from my herbarium. These it renders with the utmost truth and fidelity, exhibiting even the venation of the leaves, the minute hairs that clothe the plant, &c. &c.

It is so natural to associate the idea of *labour* with great complexity and elaborate detail of execution, that one is more struck at seeing the thousand florets of an *Agrostis* depicted with all its capillary branchlets (and so accurately that none of all this multitude shall want its little bivalve calyx, requiring to be examined through a lens), than one is by the picture of the large and simple leaf of an oak or a chesnut. But, in truth, the difficulty is in both cases the same. The one of these takes no more time to execute than the other; for the object which would take the most skilful artist days or weeks of labour to trace or to copy, is effected by the boundless powers of natural chemistry in the space of a few seconds.

To give an idea of the degree of accuracy with which some objects can be imitated by this process, I need only mention one instance. Upon one occasion, having made an image of a piece of lace of an elaborate pattern, I showed it to some persons at the distance of a few feet, with the inquiry whether it was a good representation? when the reply was, "That they were not so easily to be deceived, for that it was evidently no picture, but the piece of lace itself."

At the very commencement of my experiments upon this subject, when I saw how beautiful were the images which were thus produced by the action of light, I regretted the more that they were destined to have such a brief existence, and I resolved to attempt to point out, if possible, some method of preventing this, or retarding it as much as possible. The following considerations led me to conceive the possibility of discovering a preservative process:—

The nitrate of silver, which has become black by the action of light, is no longer the same chemical substance that it was before. Consequently, if a picture produced by solar light is subjected afterwards to any chemical process, the white and dark parts of it will be differently acted upon; and there is no evidence that, after this action has taken place, these white and dark parts will any longer be subject to a spontaneous change; or, if they are so, still it does not follow that that change will *now* tend to assimilate them to each other. In cases of their remaining *dissimilar* the picture will remain visible, and therefore our object will be accomplished.

If it should be asserted that exposure to sunshine would *necessarily* reduce the whole to one uniform tint, and destroy the picture, the *onus probandi* evidently lies on those who make the assertion. If we designate by the letter A the exposure to the solar light, and by B some indeterminate chemical process, my argument was this:—Since it cannot be shown, *à priori*, that the final result of the series of processes A B A will be the same with that denoted by B A, it will be, therefore, worth while to put the matter to the test of experiment, viz., by varying the process B until the right one be discovered, or until so many trials have been made as to preclude all reasonable hope of its existence.

My first trials were unsuccessful, as, indeed, I expected; but after some time I discovered a method which answers perfectly, and shortly afterwards another. On one of these more especially I have made numerous experiments; the other I have comparatively little used, because it appears to require more nicety in the management. It is, however, equal, if not superior, to the first in brilliancy of effect.

This chemical change, which I call the *preserving process*, is far more effectual than could have been anticipated. The paper, which had previously been so sensitive to light, becomes completely insensible to it, insomuch that I am able to show the society specimens which have been exposed for an hour to the full summer sun, and from which exposure the image has suffered nothing, but retains its perfect whiteness.

4. *On the Art of fixing a Shadow.*—The phenomenon which I have now briefly mentioned appears to me to partake of the character of the *marvellous*, almost as much as any fact which physical investigation has yet brought to our knowledge. The most transitory of things—a shadow, the most proverbial emblem of all that is fleeting and momentary—may be fettered by the spells of our "natural magic," and may be fixed for ever in the position which it seemed only destined for a single instant to occupy.

This remarkable phenomenon, whatever value it may turn out in its application to the arts, will, at least, be accepted as a new proof of the value of the inductive methods of modern science, which by noticing the occurrence of unusual circumstances (which accident, perhaps, first manifests in some small degree), and by following them up with experiments, and varying the conditions of these until the true law of nature which they express is apprehended, conducts us at length to consequences altogether unexpected, remote from usual experience, and contrary to almost universal belief. Such is the fact, that we may receive on paper the fleeting shadow, arrest it there, and in the space of a single minute fix it there so firmly as to be no more capable of change, even if thrown back into the sunbeam from which it derived its origin.

5. Before going further I may, however, add, that it is not always necessary to use a preserving process. This I did not discover until after I had acquired considerable practice in this art, having supposed at first that all these pictures would ultimately become indistinct if not preserved in some way from the change. But experience has shown to me that there are at least two or three different ways in which the process may be conducted, so that the images shall possess a character of durability, provided they are kept from the action of direct sunshine. These ways have presented themselves to notice rather accidentally than otherwise; in some instances without any particular memoranda having been made at the time; so that I am not yet prepared to state accurately on what particular thing this sort of semi-durability depends, or what course is best to be followed in order to obtain it. But as I have found that certain of the images which have been subjected to no preserving process remain quite white and perfect after the lapse of a year or two, and, indeed, show no symptom whatever of changing, while others differently prepared (and left unpreserved) have grown quite dark in one tenth of that time, I think this singularity requires to be pointed out. Whether it will be of much value I do not know. Perhaps it will be thought better to incur at first the small additional trouble of employing the preserving process, especially as the drawings thus prepared will stand the sunshine; while the unpreserved ones, however well they last in a portfolio or in common daylight, should not be risked in a very strong light, as they would be liable to change thereby even years after their original formation. This very quality, however, admits of useful application. For this semi-durable paper, which retains its whiteness for years in the shade, and yet suffers a change whenever exposed to the solar light, is evidently well suited to the use of a naturalist travelling in a distant country, who may wish to keep some memorial of the plants he finds, without having the trouble of drying them and carrying them about with him. He would only have to take a sheet of this paper, throw the image upon it, and replace it in his portfolio. The defect of this particular paper is, that in general the *ground* is not even; but this is of no consequence where utility alone, and not beauty of effect, is consulted.

6. *Portraits.*—Another purpose for which I think my method will be found very convenient, is the making of outline portraits, or *silhouettes*. These are now often traced by the hand from shadows projected by a candle. But the hand is liable to err from the true outline, and a very small deviation causes a notable diminution in the resemblance. I believe this manual process cannot be compared with the truth and fidelity with which the portrait is given by means of solar light.

7. *Paintings on Glass.*—The shadow-pictures which are formed by exposing paintings on glass to solar light are very pleasing. The glass itself, around the painting, should be blackened; such, for instance, as are often employed for the magic lantern. The paintings on the glass should have no bright yellows or reds, for these stop the violet rays of light, which are the only effective ones. The pictures thus formed resemble the productions of the artist's pencil more, perhaps, than any of the others. Persons to whom I have shown them have generally mistaken them for such, at the same time observing that the *style* was new to them, and must be one rather difficult to acquire. It is in these pictures only that, as yet, I have observed indications of *colour*. I have not had time to pursue this branch of the inquiry further. It would be a great thing if by any means we could accomplish the delineation of objects in their natural colours. I am not very sanguine respecting the possibility of this; yet, as I have just now remarked, it appears possible to obtain at least some indication of variety of tint.

8. *Application to the Microscope.*—I now come to a branch of the subject which appears to me very important, and likely to prove extensively useful, the application of my method of delineating objects to the solar microscope.

The objects which the microscope unfolds to our view, curious and wonderful as they are, are often singularly complicated. The eye, indeed, may comprehend the whole which is presented to it in the field of view; but the powers of the pencil fail to express these minutiæ of nature in their innumerable details. What artist could have skill or patience enough to copy them? Or granting that he could do so, must it not be at the expense of much most valuable time, which might be more usefully employed?

Contemplating the beautiful picture which the solar microscope produces, the thought struck me whether it might not be possible to cause that image to impress itself upon the paper, and thus to let Nature substitute her own inimitable pencil for the imperfect, tedious and almost hopeless attempt of copying a subject so intricate?

My first attempt had no success. Although I chose a bright day, and formed a good image of my object upon prepared paper, on returning at the expiration of an hour I found that no effect had taken place. I was therefore half inclined to abandon this experiment, when it occurred to me that there was no reason to suppose that the common muriate of silver was the most sensitive substance that exists to the action of the chemical rays; and though such should eventually prove to be the fact, at any rate it was not to be assumed without proof. I therefore began a course of experiments in order to ascertain the influence of various modes of preparation, and I found these to be signally different in their results. I considered this matter chiefly in a practical point of view; for as to the theory, I confess that I cannot as yet understand the reason why the paper prepared in one way should be so much more sensitive than in another.

The result of these experiments was the discovery of a mode of preparation greatly superior in sensibility to what I had originally employed; and by means of this, all those effects which I had before only anticipated as theoretically possible were found to be capable of realization.

With a sheet of this, which I shall call "*Sensitive Paper*," is placed in a dark chamber, and the magnified image of some object thrown on it by the solar microscope, after the lapse of perhaps a quarter of an hour, the picture is found to be completed. I have not as yet used high magnifying powers, on account of the consequent enfeeblement of the light. Of course with a more sensitive paper, greater magnifying power will become desirable.

On examining one of these pictures, which I made about three years and a half ago, I find, by actual measurement of the picture and the object, that the latter is magnified seventeen times in linear diameter, and in surface consequently 289 times. I have others which I believe are considerably more magnified; but I have lost the corresponding objects, so that I cannot here state the exact numbers.

Not only does this process save our time and trouble, but there are many objects, especially microscopic crystallizations, which alter so greatly in the course of three or four days (and it could hardly take any artist less to delineate them in all their details,) that they could never be drawn in the usual way.

I will now describe the *degree of sensitiveness* which this paper possesses, premising that I am far from supposing that I have reached the limit of which this quality is capable. On the contrary, considering the few experiments which I have made, (few, that is, in comparison with the number which it would be easy to imagine and propose) I think it most likely that other methods may be found, by which substances may be prepared, perhaps as much transcending in sensitiveness the one which I have employed, as that does the ordinary state of the nitrate of silver. But to confine myself to what I have actually accomplished in the preparation of a very sensitive paper.

When a sheet of paper is brought towards a window, not one through which the sun shines, but looking in the opposite direction, it immediately begins to discolour. For this reason, if the paper is prepared by daylight, it must by no means be left uncovered, but as soon as finished be shut up in a drawer or cupboard and there left to dry, or else dried at night by the warmth of a fire. Before using this paper for the delineation of any object, I generally approach it for a little time towards the light, thus intentionally giving it a slight shade of colour, for the purpose of seeing that the *ground is even*. If it appears so when thus tried to a small extent, it will generally be found to prove so in the final result. But if there are some places or spots in it which do not acquire the same tint as the rest, such a sheet of paper should be rejected; for there is a risk that, when employed, instead of presenting a ground uniformly dark, which is essential to the beauty of the drawing, it will have large white spots, places altogether insensible to the effect of light. This singular circumstance I shall revert to elsewhere; it is sufficient to mention it here.

The paper then, which is thus readily sensitive to the light of a common window, is of course much more so to the direct sunshine. Indeed, such is the velocity of the effect then produced, that the picture may be said to be ended almost as soon as it is begun.

To give some more definite idea of the rapidity of the process, I will state, that after various trials the nearest evaluation which I could make of the time necessary for obtaining the picture of an object, so as to have pretty distinct outlines, when I employed the full sunshine, was *half a second*.

9. *Architecture, Landscape, and External Nature.*—But perhaps the most curious application of this art is the one I am now about to relate. At least it is that which has appeared the most surprising to those who have examined my collection of pictures formed by solar light.

Every one is acquainted with the beautiful effects which are produced by a camera obscura, and has admired the vivid picture of external nature which it displays. It had often occurred to me, that if it were possible to retain upon the paper the lovely scene which thus illuminates it for a moment, or if we could but fix the outline of it, the lights and shadows divested of all *colour*, such a result could not fail to be most interesting. And however much I might be disposed at first to treat this notion as a scientific dream, yet when I had succeeded in fixing the images of the solar microscope by means of a peculiarly sensitive paper, there appeared no longer any doubt that an analogous process would succeed in copying the objects of external nature, although indeed they are much less illuminated.

Not having with me in the country a camera obscura of any considerable size, I constructed one out of a large box, the image being thrown upon one end of it by a good object glass fixed in the opposite end. This apparatus being armed with a sensitive paper was taken out in a summer afternoon and placed about one hundred yards from a building favourably illuminated by the sun. An hour or two afterwards I opened the box, and I found depicted upon the paper a very distinct representation of the building, with the exception of those parts of it which lay in the shade. A little experience in this branch of the art showed me that with smaller cameræ obscuræ the effect would be produced in a smaller time. Accordingly I had several small boxes made, in which I fixed lenses of shorter focus, and with these I obtained very perfect but extremely small pictures; such as without great stretch of imagination might be supposed to be the work of some Lilliputian artist. They require indeed examination with a lens to discover all their minutiæ.

In the summer of 1835 I made in this way a number of representations of my house in the country, which is well suited to the purpose, from its ancient and remarkable architecture. And this building I believe to be the first that was ever yet known *to have drawn its own picture.*

The method of proceeding was this; having first adjusted the paper to the proper focus in each of these little *cameræ*, I then took a number of them with me out of doors and placed them in different situations around the building. After the lapse of half an hour I gathered them all up, and brought them within doors to open them. When opened, there was found in each a miniature picture of the objects before which it had been placed.

To the traveller in distant lands who is ignorant, as too many unfortunately are, of the art of drawing, this little invention may prove of real service; and even to the artist himself, however skilful he may be. For although this natural process does not produce an effect much resembling the productions of his pencil, and therefore cannot be considered as capable of replacing them, yet it is to be recollected that he may often be so situated as to be able to devote only a single hour to the delineation of some very interesting locality. Now, since nothing prevents him from simultaneously disposing, in different positions, any number of these little *cameræ*, it is evident that their collective results when examined afterwards, may furnish him with a large body of interesting memorials, and with numerous details which he had not had himself time either to note down or to delineate.

10. *Delineations of Sculpture.*—Another use which I propose to make of my invention is for the copying of statues and bas reliefs. I place these in strong sunshine, and put before them at a proper distance, and in the requisite position, a small camera obscura containing the prepared paper. In this way I have obtained images of various statues, &c. I have not pursued this branch of the subject to any extent: but I expect interesting results from it, and that it may be usefully employed under many circumstances.

11. *Copying of Engravings.*—The invention may be employed with great facility for obtaining copies of drawings or engravings or facsimiles of MSS. For this purpose the engraving is pressed upon the prepared paper, with its engraved side in contact with the latter. The pressure must be as uniform as possible, that the contact may be perfect; for the least interval sensibly injures the result, by producing a kind of cloudiness in lieu of the sharp strokes of the original.

When placed in the sun, the solar light gradually traverses the paper, except in those places where it is prevented from doing so by the opaque lines of the engraving. It therefore of course makes an exact image or print of the design. This is one of the experiments which Davy and Wedgwood state that they tried, but failed, from want of sufficient sensibility in their paper.

The length of time requisite for effecting the copy depends on the thickness of the paper on which the engraving has been printed. At first I thought that it would not be possible to succeed with thick papers; but I found on trial that the success of the method was by no means so limited. It is enough for the purpose, if the paper allows any of the solar light to pass. When the paper is thick, I allow half an hour for the formation of a good copy. In this way I have copied very minute, complicated, and delicate engravings, crowded with figures of small size, which were rendered with great distinctness.

The effect of the copy, though of course unlike the original, (substituting as it does lights for shadows, and *vice versa*), yet is often very pleasing, and would, I think, suggest to artists useful ideas respecting light and shade.

It may be supposed that the engraving would be soiled or injured by being thus pressed against the prepared paper. There is not much danger of this, provided both are perfectly dry. It may be well to mention, however, that in case any stain should be perceived on the engraving, it may be readily removed by a chemical application which does no injury whatever to the paper.

In copying engravings, &c., by this method, the lights and shadows are reversed, consequently the effect is wholly altered. But if the picture so obtained is first *preserved* so as to bear sunshine, it may be afterwards itself employed as an object to be copied; and by means of this second process the lights and shadows are brought back to their original disposition. In this way we have indeed to contend with the imperfections arising from two processes instead of one; but I believe this will be found merely a difficulty of manipulation. I propose to employ this for the purpose more particularly of multiplying at small expense copies of such rare or unique engravings as it would not be worth while to re-engrave, from the limited demand for them.

I will now add a few remarks concerning the very singular circumstance, which I have before briefly mentioned, viz. that the paper sometimes, although intended to be prepared of the most sensitive quality, turns out on trial to be wholly insensible to light, and incapable of change. The most singular part of this is the very small difference in the mode of preparation which causes so wide a discrepancy in the result. For instance, a sheet of paper is all prepared at the same time, and with the intention of giving it as much uniformity as possible; and yet, when exposed to sunshine, this paper will exhibit large white spots of very definite outline, where the preparing process has failed: the rest of the paper, where it has succeeded, turning black as rapidly as possible. Sometimes the spots are of a pale tint of cœrulean blue, and are surrounded by exceedingly definite outlines of perfect whiteness, contrasting very much with the blackness of the part immediately succeeding. With regard to the theory of this, I am only prepared to state as my opinion at present, that it is a case of what is called "unstable equilibrium." The process followed is such as to produce one of two definite chemical compounds;

and when we happen to come near the limit which separates the two cases, it depends upon exceedingly small and often imperceptible circumstances, which of the two compounds shall be formed. That they are both definite compounds, is of course at present merely my conjecture; that they are signally different, is evident from their dissimilar properties.

I have thus endeavoured to give a brief outline of some of the peculiarities attending this new process, which I offer to the lovers of science and nature. That it is susceptible of great improvements I have no manner of doubt; but even in its present state I believe it will be found capable of many useful and important applications besides those of which I have here given a short account.

The subject (says Mr. Talbot) naturally divides itself into two heads—the preparation of the paper, and the means of fixing the design. In order to make what may be called ordinary photogenic paper, the author selects, in the first place, paper of a good firm quality, and smooth surface; and thinks that none answers better than superfine writing paper. He dips it into a weak solution of common salt, and wipes it dry, by which the salt is uniformly distributed throughout its substance. He then spreads a solution of nitrate of silver on one surface only, and dries it at the fire. The solution should not be saturated, but six or eight times diluted with water. When dry, the paper is fit for use. He has found, by experiment, that there is a certain proportion between the quantity of salt and that of the solution of silver which answers best, and gives the maximum effect. If the strength of the salt is augmented beyond this point, the effect diminishes, and, in certain cases, becomes exceedingly small. This paper, if properly made, is very useful for all ordinary photogenic purposes. For example, nothing can be more perfect than the images it gives of leaves and flowers, especially with a summer sun. The light passing through tthe leaves delineates every ramification of their nerves. If a sheet of paper, thus prepared, be taken and washed with a saturated solution of salt, and then dried, it will be found (especially if the paper has been kept some weeks before the trial is made), that its sensibility is greatly diminished, and, in some cases, quite extinct. But if it be again washed with a liberal quantity of the solution of silver, it becomes again sensible to light, and even more so than it was at first. In this way, by alternately washing the paper with salt and silver, and drying it between times, Mr. Talbot has succeeded in increasing its sensibility to the degree that is requisite for receiving the images of the camera obscura. In conducting this operation, it will be found, that the results are sometimes more, and sometimes less satisfactory, in consequence of small and accidental variations in the proportions employed. It happens sometimes that the chloride of silver is disposed to darken of itself, without any exposure to the light—this shows, that the attempt to give it sensibility has been carried too far. The object is, to approach to this condition as near as possible, without reaching it; so that the substance may be in a state ready to yield to the slightest extraneous force, such as the feeble impact of the violet rays when much attenuated. Having, therefore, prepared a number of sheets of paper, slightly different from one another in the composition, let a piece be cut from each, and, having been duly marked or numbered, let them be placed side by side in a very weak diffused light, for about a quarter of an hour; then, if any one of them, as frequently happens, exhibits a marked advantage over its competitors, Mr. Talbot selects the paper which bears the corresponding number to be placed in the camera obscura.

With regard to the second object—that of fixing the images—Mr. Talbot observed, that, after having tried ammonia, and several other re-agents, with very imperfect success, the first which gave him a successful result, was the iodide of potassium, much diluted with water. If a photogenic picture is washed over with this liquid, an iodide of silver is formed, which is absolutely unalterable by sunshine. This process requires precaution; for, if the solution is too strong, it attacks the dark parts of the picture. It is requisite, therefore, to find, by trial, the proper proportions. The fixation of the pictures in this way, with proper management, is very beautiful and lasting. The specimen of lace, which Mr. Talbot exhibited to the society, and which was made five years ago, was preserved in this manner. But his usual method of fixing is different from this, and somewhat simpler—or, at least, requiring less nicety. It consists in immersing the picture in a strong solution of common salt, and then wiping off the superfluous moisture, and drying it. It is sufficiently singular that the same substance which is so useful in giving sensibility to the paper, should also be capable, under other circumstances, of destroying it; but such is, nevertheless, the fact. Now, if the picture which has been thus washed and dried, is placed in the sun, the white parts colour themselves of a pale lilac tint, after which they become insensible. Numerous experiments have shown the author that the depth of this lilac tint varies according to the quantity of salt used, relatively to the quantity of silver; but by properly adjusting these, the images may, if desired, be retained of an absolute whiteness. He mentions, also, that those preserved by iodine are always of a very pale primrose yellow, which has the extraordinary and very remarkable property of turning to a full gaudy yellow, whenever it is exposed to the heat of a fire, and recovering its former colour again, when it is cold.

Ship-building.—The ship-builders of Liverpool, have seldom, if ever, been so busy as they are at present. All the yards on both sides the Mersey are occupied by vessels, of various tonnage, in process of building; and more frames would be laid down if the builders could undertake the work. The ship-builders along the west and the east coast are equally busy, and have frequent occasion to refuse proffered contracts for building vessels. All these circumstances show that the shipping interest is in a very flourishing state.—*Liverpool paper.*

NELSON MEMORIAL.

Merely a single visit to Mr. Rainy's Gallery—just before our presen number was going to press, and when of course we ourselves were greatly hurried,—does not enable us to enter into any critical remarks on any of the designs and models individually, or even to give a general opinion as to the average talent displayed in this competition, further than that satisfactory as the *coup d'œil* of the exhibition itself is, we observed very few designs characterised by originality of invention or propriety of adaptation to the intended site. On the contrary, the larger majority, we apprehend, would be found, on deliberate examination, to be but poorly calculated to suit either the area itself, or the surrounding buildings.

DESIGN BY W. RAILTON, ARCHITECT.

To which the first premium is proposed to be adjudged by the first Committee.

The design makes no pretension whatever to originality, being no more than a fluted Corinthian column, 174 feet high, on a pedestal ornamented with reliefs, and surmounted by a statue 17 feet high, consequently for want of some basement or substructure will be apt to look too small, except as merely a lofty central ornament in the square.

The following description of the two other prizes are by their respective authors:—

DESIGN, BY E. H BAILY, R.A.

To which the committee propose to award the second prize.

Description.—An Obelisk raised to the memory of Nelson by his grateful country. At the base, our great Naval Commander is represented supporting the Imperial Standard; on his left stands the Genius of Britain, hailing with affection the Hero of Trafalgar; his attendant, Victory, being seated on his right. At the back of the Obelisk rests the Nile—Neptune with the subordinate Deities of the Ocean, form a Triumphal Procession round the Rock on which the Monument is placed, thereby indicating that the Victories of Nelson were as extensive as the Element on which h fought.

Dimensions.—The height of the Monument is intended to be 60 feet; the diameter of the steps the same extent; and the height of Nelson to be nine feet, the other figures in proportion, as in the sketch.

Estimate.—To execute the whole monument in Ravaccioni Marble, (the same as the arch before Buckingham Palace is built of) 22,000*l.*—if executed in Bronze, 30,000*l.*

DRAWINGS AND MODEL BY CHARLES FOWLER, ARCHITECT, AND R. W. SIEVIER, SCULPTOR.

To which the committee propose to award the third prize.

This design has been composed upon the principle of combining Architecture and Sculpture; with a view to obtain a more striking effect from their union than either is calculated to produce separately; the one by its forms and mass, to arrest the attention and make a general impression, which may be heightened and perfected by the more refined and interesting details of the other. It would appear from the result of existing instances that a mere structure cannot properly convey the feeling or produce the effect intended by a Monument, designed to commemorate any celebrated character or event. On the other hand a Statue or Sculpture Groupe is inefficient for want of mass and general form; the former is appreciated as a distant object, and the latter only on close inspection. The desideratum, therefore, lies in avoiding these objections, or rather in combining the advantages which peculiarly belong to each art, so that the many who pass by may be struck with the general aspect of the Monument, and the few who may pause to examine its details may find their first impressions carried forward and perfected by the beauty and significance of its historical illustrations.

With respect to the design now submitted, the endeavour has been to render it characteristic and appropriate to the occasion, avoiding plagiarism but without affecting novelty. The rostrated decorations of the pedestal, and its accessories proclaim it at once to be a naval trophy; and the hero to be commemorated will be not less plainly indicated; whilst the sculpture and other details will set forth his achievements.

In regard to the structure, simplicity and strength are the distinguishing qualities of the basement, which is proposed to be constructed of granite, in large blocks, so as to be striking for their massiveness, solidity, and giving dignity to the superstructure. The pedestals at the angles of the platform are to be surmounted with piles of trophies executed in bronze, and crowned with lamps to light both the area and monument; massive granite basins are set to receive the running fountains on three sides, the fourth being reserved for an entrance to the structure within. The colossal figures seated against the four fronts of the pedestal, are designed to represent Britannia, Caledonia, Hibernia, and Neptune, distinguished by their appropriate insignia and attributes.

On the south front of the pedestal, and at a legible distance from the spectator, is proposed to be inscribed a brief eulogium of the hero,—some attempt at which, by way of illustration, is made in the drawing, without presuming to anticipate that delicate task, which will properly devolve upon other and more able hands. The opposite side is intended to contain the historical or matter-of-fact inscription, comprising also a record of the erection of the monument. The other two sides are to have each a shield of arms in relief, encircled by a wreath. The cap or cornice of the lower pedestal is decorated by antique prows of vessels, to give the rostrated character, enriched with festoons of oak and marine ornaments.

The middle compartment of the structure contains on the four faces of the dado simply the names of the four principal actions in which Nelson was engaged; and in the panel over each is a representation in *Basso relievo* of some striking incident, in each battle—the front being distinguished by the grand catastrophe, which formed at once the climax of his achievements, and the termination of his brilliant career.

In order to give character, as well as to provide for an unusually bold projecture, the Gallery above is supported on Cannons, in lieu of the usual architectural consoles: and the intervals in the soffite are enriched with bombs and grenades. The railing of the gallery is composed of decorations and emblems, having reference to the occasion, so as to combine ornament with characteristic expression.

The upper compartment of the monument is distinguished by its circular form, and is more completely charged with decoration, illustrative of the honors which Nelson had achieved. The four large wreaths, embracing the entire circuit of the pedestal, contain respectively the Naval Crown, the Viscount's Coronet, the Mural Crown, and the Ducal Coronet. From these wreaths are suspended the decorations of the four "Orders" to which he belonged.

The frieze of this pedestal is entirely occupied by the heraldic motto, which happens to be peculiarly appropriate to the occasion. The ornaments surmounting the cornice, which are analogous in form and application to the Grecian antefixæ, are composed of escallop shells, and the cupola is to be of copper gilt.

The Statue of Nelson crowns the whole, and is to be executed in bronze, about sixteen feet in height, and the entire height of the structure and statue will be 120 feet from the area of the square—viz: eleven feet more than the Column of the Duke of York.

The monument, with all its decorations and accessories, to be completed in the most perfect style for the *sum of twenty-five thousand pounds*. This we are ready to undertake, and to give security for the accomplishment. Having taken the pains to arrive at the conclusion upon which this *bona fide* offer is grounded with all the responsibility it envolves, it is hoped that due precautions will be observed in testing the accuracy of the estimates generally, so as to avoid the delusion that too commonly occurs, which besides misleading the promoters of the undertaking inflicts an injustice in those who are more careful and scrupulous in their proposals.

RESTORATIONS OF ANCIENT MONUMENTS OF ROME, &c.

EXECUTED BY THE PENSIONARY ARCHITECTS OF THE ROYAL ACADEMY OF FRANCE.

(Extract from a Paper sent by M. Vaudoyer, of Paris, Architect, to T. Donaldson Esq., Architect; read before the Royal Institute of British Architects.)

Nos.	Monuments.	Architects.
1.	Temple of Modesty	Dubut.
2.	Temple of Vesta	Coussin
3.	Mars Ultor	Gasse.
4.	Tower of Metellus	Grandjean.
5.	Antoninus & Faustina	Ménayer:
6.	Arch of Titus	Guénepin.

32.*	Circus of Caracalla	Destouches.
33.*	Temple of Serapis	Caristie.
34.*	Temple of Concord	Constant.

* In hand, but not yet finished.

These 34 restorations, with from 8 to 10 drawings each, forming in all more than 300, are sketched upon canvas, and richly bound, each set in a distinct volume of the same shape and size, 3 feet 3 inches English in height. They are also accompanied by a very curious and erudite historical memoir.

This work is not a production of the imagination, but is based for the most part upon positive materials, which up to the present time have never yet been examined and studied with so much judgment and perseverance, and is the faithful record of invaluable monuments, which are daily perishing, and of which many will be lost to posterity—and will one day form a work of the greatest interest, not only with regard to architecture, but to the history of archæology and the fine arts in general.

The Minister of the Interior proposes to publish them for the use of French artists, and for circulation in foreign countries.

Ventilators of the New Court, Old Bailey.—Mr. Perkins has caused subterraneous chambers of a capacious size to be formed, in which are placed coils of hot-water pipes, and others containing cold air, which are so arranged that by turning a valve, the warmed fresh air is admitted through apertures made in the floor and wainscoting of the court—so that a comfortable temperature may be preserved, whether the court be more or less crowded. The foul air, which naturally generates in a crowded court, is drawn off by a shaft under the prisoner's dock, as well as from the gallery and ceiling, which, communicating with large curves on the roof, the foul air makes a thorough exit, and fresh air, either warm or cold, can be supplied in such quantities as necessity may require. Great credit is conceded to Mr. Perkins for his excellent contrivance, and the improvement which he effected upon the antique method of ventilating the courts by canvas bags, and warming them with braziers filled with charcoal. There is one matter connected with this contrivance which ought not to be overlooked. The prisoners for trial on each day were placed in damp and unwholesome cells, where they were kept shivering with cold in the winter months. A genial warmth now pervades their gloomy recesses, so that for the time being their unenviable situation is rendered less intolerable.—*Morning Advertiser.*

REVIEWS.

Observations on Lime, Calcareous Cement, Mortars, Stuccos, and Concrete; and on Puzzolanas, Natural and Artificial; together with Rules deduced from Numerous Experiments for making an Artificial Water Cement, &c. By C. W. Pasley, C.B., Colonel in the Corps of Royal Engineers, F.R.S., &c. London: John Weale. 1838.

(Second Notice.)

We now take the opportunity of again referring to Colonel Pasley's work, less for any purposes of criticism than to afford our readers an opportunity to judge of the correctness of the views which we adopted, in recommending it as a highly practical work. In the first extract, of which we shall avail ourselves, the Colonel very properly supports the necessity of specifying the proportions of lime to be used for making mortar by weight, and not, as is generally the case, by measure.

For this purpose I beg to suggest, that whenever the common mode of measuring lime in lumps from the kiln has been intended and used, this shall be particularly specified, and that the average weight per cubic foot of the lime in this state, estimated, however, not from the contents of a single cubic foot measure, but from that of some larger measure, which need not except 10, and should not be less than 5 cubic feet shall also be recorded.* In fact, supposing it required to mix 3 measures of sand with 1 measure of Halling lime, it would afford much greater accuracy and uniformity in the quality of the mortar, to direct 3 cubic feet of sand to be mixed with 37lbs. of quick lime fresh from the kiln, or as a 10 feet measure is most convenient, let it be stated that the mortar shall be made in the proportion of 10 cubic feet of sand to about 124lbs. of lime, which is nearly equivalent to the former; and the mode of measuring the lime from the kiln should also be described or specified, because, although it may be presumed that fair and full level measure is intended or has been used, it is best to leave nothing doubtful.

When the lime from the kiln is directed to be ground to a fine powder, it is still more essential to define the mode in which it is to be or has been measured, whether lightly, or after temporary compression only, or under actual compression.

In respect to sand, the custom is to serve it in by stricken measure, in whatever state it may be at the period of sale, which may vary between more or less dry or wet, according to circumstances, known to the persons who use it, but not to others unless explained, amongst which circumstances the state of the weather has its influence; for sand is not kept under cover, but laid out in masses in the open air. Hence, in order that we may have any precise knowledge of the real proportion which the sand bears to the lime, in the mortar of any work of importance, the person who describes such mortar ought to specify particularly the state in which the sand was measured, whether absolutely dry, or damp, or wet; because the actual quantity of sand obtained by the same measure in these three states, varies considerably between the second, which is the minimum, and the latter, which is the maximum of quantity. But the sand used for building in this country is scarcely ever in either of these two extremes of perfectly dry or wet. It generally varies only between more or less damp, and probably the difference in real quantity, between equal measures of it in those two states, does not exceed one-tenth in the practice of building at any one place. To describe accurately the state in which it has generally been used for the mortar of any important work, the author should specify not only the mean space occupied by it in that state, but also the spaces which the same quantity of the same sand is capable of occupying when perfectly dry, and when thoroughly wet, stating also its weight per cubic foot when perfectly dry, there being no certainty as to the weight of sand in any other state. Moreover to enable a person, who does not know the sort of sand obtained from a particular locality, to understand the nature of it, the size of the particles should be described in the way that has been done by M. Vicat, by stating the diameter of the smallest and of the largest grains composing it, the latter of which may be sufficiently defined by describing the sort of screen through which even very fine sand is almost always sifted, to exclude pieces of wood or other extraneous substances generally found in it. When sand and gravel are to be mixed together, in any given proportion, the size of both should also be described in the same manner; and even in using some natural mixture of these ingredients, such as Thames ballast, in the mortar of any important work, it is desirable that it should be defined in the same manner, for the use not only of foreigners, but of our own countrymen, in those parts of the United Kingdom where it is not used, although those who are accustomed to the daily use of it will of course need no such description.

* Whilst investigating the subject of measures and weights, I found by repeated trials that a 10-cubic-feet measure made of two rectangular wooden cases, open at top and bottom, and each measuring 2 feet by 2½ feet square in the clear and 1 foot high, either to be used separately as 2 five-cubic-feet measures, or jointly by placing one upon the other, was a more convenient arrangement for the measurement of dry materials, as well as for calculation, than the cubic yard measure in common use, which is also usually made in two parts, each composed of a similar case 3 feet square in the clear and 18 inches high. In small buildings, where only few masons or bricklayers are employed, the half of the 10-cubic-feet measure may be the most convenient, as small quantities of mortar only are required to be mixed at a time. But to use a smaller measure than this would not afford a satisfactory estimate of average quantity, because the cubic foot of lime in lumps, measured singly in a one-cubic-foot measure is not equal to one-tenth part of the contents of a ten-cubic-feet measure nor to one-fifth part of the contents of a five-cubic-feet measure.

We have next detailed several experiments upon brick and cement beams, combined with hoop iron, laid horizontally between the joints. From the experience obtained in this investigation, the Colonel derives the following conclusions :—

That cement bond, consisting of four or five courses of brickwork laid in pure cement, if strengthened by longitudinal pieces of hoop iron in all the joints, may be used to supersede not only the wooden lintels of doors and windows, but all timber bond generally in the walls of buildings, as suggested in Article 234, which was written before we had tried these last experiments. In using hoop iron bond in walls, the irons should extend, if possible, the whole length of each wall in one piece; but if a break be necessary, the adjoining ends need not be united together by the blacksmith, but turned down at right angles into one of the vertical joints of the wall by the bricklayers themselves. Without hoop iron bond, on the contrary, the additional strength communicated by cement alone would not suffice in difficult cases.

It is to be observed, however, that a continued string of four or five courses of cement and hoop iron bond, in the walls of a building, would not be exposed by any means to the same strain as our experimental brick beams; for it would not have to bear much more than its own weight in all the unsupported parts over a door or a window, there being other windows above those, and in all the intermediate portions of the wall corresponding with the ends of our experimental brick beams, the courses of cement bond alluded to would not only be supported from below, but their strength would be greatly increased by the weight of the solid parts of the wall above, it being well known that all beams have a much greater resistance, when firmly fixed, than when merely supported at their ends, which Mr. Barlow in his able and useful treatise on the strength and stress of timber estimates from his own experiments, as being in proportion to the numbers of 3 and 2. Besides which, 10 feet between the bearings is a much greater width than would be given in practice to the windows, or even to the doors of the largest building, unless the latter were carriage-gateways, which are more usually covered by semicircular or elliptical arches, than by flat arches or straight lintels.

It only remains further to remark, that the flattest and thinnest brick and cement arch has sufficient power to resist great pressure, in openings of 10 or even 15 feet, as was proved by one of our former experiments; though a straight brick and cement beam is not to be recommended, over such openings, unless consolidated by hoop iron bond.

We have then some experiments on cements, tiles, and bricks, applied for steps or staircases ; an investigation bearing upon a very useful professional subject.

In both of these artificial steps the fracture takes place near to the wall, but that part of each, though entirely broken through, was suspended by the irons, which did not break, but elongated or were drawn out from their original position within the wall, just enough to admit of the far end of each step striking the ground in falling. In reference to the consideration before stated, the stone step may be considered to possess a resistance of about 5 times, the plain tile step a resistance of about 3 times, and the paving tile step a resistance fully double of the greatest weight, ever likely to press upon one step of a geometrical staircase 4 feet wide; that is, provided its width, which was only 12 inches, had been increased to 14 or 15 inches, which is the more usual width of the steps of such staircases, and which would of course increase its resistance in proportion. I shall observe also, that as the resistance of plain tiles and of paving tiles without cement was proved to be very nearly equal by our former experiments recorded in Table XVIII. (324), the marked superiority of resistance of the plain tile and cement step over the paving tile and cement step, though both formed of materials equally or nearly equally strong, may probably be ascribed in this experiment to the former being composed of a much greater number of tiles and therefore having a much greater number of cement joints than the latter. Notwithstanding, however, this inferiority of the paving tiles, I would recommend their being used in preference to plain tiles, if the expedient of building staircases with artificial steps composed of tiles, with cement and hoop iron bond, should ever be adopted, because the paving tile step is quite strong enough, and gives much less trouble in the workmanship than any very small sort of tiles, such as plain tiles would do. But instead of using tiles 12 inches square and 1½ inch thick, like the common paving tiles of this country, they should be made 15 inches long, 12 inches wide, and about 1½ or 1¾ inch thick only, so that 4 courses might be used for the steps of the principal staircase, and 5 courses for those of a second rate staircase of the same house, the latter of which are always made higher and also usually narrower than the former. And in order to break joint properly, it would be better to make a proportion of half tiles of the same length, but only six inches wide, than to cut whole tiles in two for this purpose. . . . . .

Colonel Pasley strongly asserts the superiority of cement mortar over hydraulic lime, in the construction of wharf and river walls. Several instances are given of the failure of hydraulic lime for this purpose, and particularly one remarkable instance—in the case of a wall which had stood forty years without showing any symptoms of decay. The Colonel observes,—

Instead of plain tiles, long thin stones, such as schists, or coarse slates not good enough for the roofs of buildings, might be used for the same purpose of forming artificial steps, when united by cement and strengthened by hoop iron bond; but in all materials not before tried, it would be proper to make an experiment step beforehand to ascertain the most suitable dimensions of the parts, and the best mode of breaking bond in putting them together. About three months should be allowed for the cement to set, before such steps are let into the walls of a building. • •

I have seen an official drawing, of 1789, evidently in reference to a project for the completion of this wharf, a section contained in which very nearly agrees with the present profile of the wall, which is known to have been finished more than 40 years,* and I have ascertained by inquiry that no appearance of failure was ever noticed until the year 1825, when part of it was observed to have bulged a little forward, but no material change took place until some yers afterwards, when a substantial granite coping was laid in front of the wall, as a substitute for the timber capping and land ties, which had become rotten. The weight of this coping, which could have done no harm, had the mortar of the brickwork been good, has undoubtedly accelerated the separation of the front of the wall from the counterforts, which action has been gradually in progress, but exerted itself more powerfully, as soon as the bond timber and lower row of bond ties became rotten.† . .

The circumstance of this wall having remained perfect for at least 27 years after it was finished, and of some parts of it still remaining so, may be considered a proof, that the profile was sufficient, if better mortar had been used, for the wall, which was about 24 feet high and had offsets or footings at bottom, had an exterior slope of one tenth of its height, and would have been 6½ feet thick at top, if the back of it had been carried up vertically, instead of which its thickness was reduced to 4 feet at top, by a step in rear, about 7½ feet below the level of the ground. It had very substantial counterforts measuring rather more than 6 feet square in plan, at central intervals of 18 feet, and terminating about 4 feet below the same level, that is several feet higher than the step at the back of the wall, the lower part of which by being thicker was in itself a sort of counterfort to the upper part of it, in consequence of which the front part of the wall being the thinnest and less capable of resisting the pressure of earth in rear, separated from the back part in rear of the said step, whereas had the whole back of the wall being carried up vertically, the separation, resisted by a greater mass of brickwork, would have been less considerable, and would have taken place farther back, entirely behind the back of the wall, and in front of the counterfort.

In the following judicious observations the Colonel points out the cases, in which hydraulic lime may be used, and those in which it ought to be avoided.

For the general purposes of Civil Architecture, concrete should therefore, I again repeat, be chiefly confined to foundations; but I conceive that the failure of the new concrete foundation of the Storehouse in Chatham Dock-yard has proved, that it is generally, or at least when formed as Mr. Ranger has usually done, with rather a greater proportion of lime than was originally adopted by Sir Robert Smirke, liable to settlements like lime mortar, which in fact forms the principal part of it. Hence care must be taken, in commencing the brick footings of a building over a concrete foundation, not only to use cement mortar and hoop iron bond, in order to do away the necessity of the more expensive expedients of Yorkshire landing stones and chain timbers, but also to construct inverted arches under all the proposed openings for doors and windows, in order to equalize the pressure.

In using concrete for the backing of wharf walls or other retaining walls, care must be taken to connect it well with the stone or brick facing of the wall, but I apprehend, that the wall and its backing should be constructed of a sufficiently substantial profile to dispense with counterforts, because a substance having so little resistance and adhesiveness, as concrete, would admit of the wall in front being forced away from the counterforts, by the pressure of earth acting upon the back of it; as has often occurred to retaining walls and their counterforts, even when built of brickwork.

In works of Fortification, whilst I have already reprobated the use of concrete for casemates or vaults, yet as the severest frosts seem to destroy those surfaces of concrete only, which are alternately saturated with water and then exposed to the atmosphere, as in the facing of the wharf walls of tide rivers, I see no reason to withdraw the opinion formed by me, previously to the recent failures in her Majesty's Dock-yards at Woolwich and Chatham, that it may be used for retaining walls not exposed to the action of water, as in the sea wall at Brighton improperly so termed, and also for the revetments of fortresses in the peculiar situations before mentioned, in which it is possible that it might be so much cheaper than regular masonry or brickwork, that although greatly inferior in resistance and consequently liable to be much sooner and more easily breached, whether by battering guns or by mining, this disadvantage would not be a sufficient argument against the use of it in those situations.

We omitted to mention in its proper place that the Colonel has discovered a cement, which appears from the trials to which it has been subjected, stronger than Roman cement, and very useful as an hydraulic mortar. It is composed of 4 parts of pure chalk, and 5½ parts of fresh blue alluvial clay; and the method of preparing, mixing and calcining is fully described.

At the end of the work is an appendix, giving a description and the

* From this drawing one would infer, that a brick wall with counterforts, either finished or perhaps only in progress, existed in 1789, which it was proposed to face with stone. But this is conjecture, as I have never seen any document explanatory of the drawing alluded to.

† To guard against this evil, chain cables or strong iron bolts or bars have recently been used by the engineers of the present day as land ties, for wharf walls. These are particularly necessary in wharfs faced with iron, which has very little stability in itself, and must therefore be aided by long land ties running through the backing of the wharf, and well secured to some immoveable objects in rear.

composition of most of the cements and mortars used in this country, so as to give the architect and engineer much useful information. In this appendix the Colonel has given a description of Mr. Brunel's experimental brick arch, the dimensions and details of which he states that he has derived chiefly from the sixth number of this journal. This account he believes to be correct, except that *nett* cement was used instead of mortar, composed of cement and sand, as stated by us. In consequence of this correction by the Colonel, we again made enquiries of the bricklayer who assisted in the construction of the arch, and who still persists that cement and sand were used, and not *nett* cement; we have also procured a piece of the brickwork from the arch, and we feel bound to state that from its appearance it seems to be constructed of nett cement.

We do not think it necessary to say anything further in praise of this work, for we feel assured that the extracts which we have given from it are sufficient to convince our readers of its highly valuable and practical nature. It is, in fact, a work which every member of the profession may refer to with advantage, as he may place every reliance upon the correctness of the experiments which are there detailed.

Life of Thomas Telford, written by HIMSELF. *Edited by* JOHN RICKMAN. London: Payne and Foss, 1838.

We have purposely delayed our notice of this work, that we might not be accused of not paying due attention to it, or hastily passing a judgment unfavourable to its claims. It is a work which was anxiously awaited by the profession, and naturally looked for as a great accession to the stores of scientific literature, but we regret that its appearance has deceived these expectations. The "Life of Telford," described by his works, offered a field which, in judicious hands, could not fail to have produced a book of standard reputation. The price also, of eight guineas, demanded for the present volume, and the circumstance of funds having been provided for its execution by Telford himself, is so high, as to require great exertions to justify such a charge, and we vainly hoped that, from among the papers of Telford, many valuable ideas would thus have acquired a greater circulation. A large volume of plates is certainly given, but they contain so much that is trite, and so much that is useless, that they greatly derogate from the value of the mass.

The work has been thrown into the form of a narrative, under the plea of insuring greater ease and freedom, but the subject has been so mutilated by the editor, that it is neither an autobiography nor anything else. The few snatches of Telford that are left, give a promise of what he was capable of effecting; and we should have derived an invaluable example in the relation of a progress through life, of which he has given us such a modest commencement. Telford, however, never lived to finish his work, and his editor has taken such liberties, that if anything of Telford is left, it is principally his faults. He has warped the current of the subject to make room for irrelevant dissertations; the descriptions of works, instead of showing the minute care with which an author would dwell on his designs, are derived from the commonest sources, and a considerable part of the work is occupied with parliamentary reports, superannuated documents, Roman baths, and other men's works. We deplore this catastrophe, as it is one which we have heard greatly regretted by many members of the profession, and we had certainly expected something better when we looked at other engineering works of less pretensions. The money and reputation of Telford have been lavished on it, but it shrinks in the scale when compared with such volumes as the "Public Works of England," "Railway Practice," the reprint of "Smeaton's Reports," or the new edition of "Tredgold's Steam Engine;" any one of which contains far more practical information, at half the cost, than this "splendid work of Telford." We need scarcely say that the editor has fully redeemed his pledge of "not requiring classification of subjects," and that he has produced a most admirable and agreeable confusion. As to the literary portion of the work, which Telford's diffidence imposed on the editor, it is very scanty and unsatisfactory; and although we could excuse this from Telford, we can make no concession to the editor. Instead of this work being called the "Life of Telford, written by himself," it should be the "Life of Telford," with the part of "himself" by Mr. Rickman; and thus the name of Telford would be redeemed from the slur cast on it by this compilation. Altogether, Telford is most singularly unfortunate, that when, having taken some care to maintain his reputation, he should have confided the task to one so manifestly incompetent. To deny that the work has some merit would be absurd; for it would be impossible that Telford could be associated with an enterprise without conferring some lustre on it; but our opinion of the compilation as a whole is, that neither the quantity of information communicated, nor its quality, are at all commensurate with the extent of its assumptions or the magnitude of its price. The drawings of Telford, it is true, are to be found in the library of the Institution of Civil Engineers, but who can find time to study them there? Few men can afford to sacrifice, in such researches, their leisure and their time.

The work commences with a descriptive narrative of the works of Telford, and such short snatches of his life as the editor has left unpruned. Thomas Telford was an orphan of a working mason in an obscure part of Scotland, and this avowal which his sense of innate dignity prompted stands in solitary contrast with the lack of farther information. We find him successively working at Edinburgh and at Somerset House, then of a sudden superintending works in Portsmouth Dock-yard, and afterwards county surveyor of Shropshire. We see no proof of merit which could warrant this rapid rise, and we look in vain to the work for an explanation of the circumstances which thus determined his career in future life. We can appreciate the studious and laborious attention with which he cultivated his mental powers, but we must look to other operations for the causes of his promotion, and we may believe that had it not been for the patronage of his schoolfellow, Sir William Johnstone Pulteney, his career might have been in a lower grade, and his reputation of less extent. As county surveyor, we find Telford first engaged as a civil engineer; and here he had full scope for his favourite pursuit of bridge-building. The first bridge the construction of which he superintended was one of three arches over the Severn, and soon afterward he constructed the second cast-iron bridge in England, at Buildwas, the first having been at Colebrookdale. This consisted of a single arch of 130 feet span, of which the iron-work was executed, in 1796, by the Colebrookdale Company, by contract with the county magistrates, for 6,034*l.* 13*s.* 3*d.* Of this bridge an engraving is given in the Atlas; and besides these, he erected forty smaller bridges in the county. This led to further employment in the same line, and he also attempted some works as an architect, though with very little credit to his taste. The parish church of Bridgenorth, in Shropshire, which had been the chapel of a Norman Castle, he rebuilt in a mixture of the Greek and Roman styles.

In 1793 we find him engaged in one of his first great works, the Ellesmere Canal, the managing committee of which was principally composed of county magistrates. Telford's management of this complicated work was such as fully to justify their confidence in him, and he thus acquired new means of displaying the boldness and originality of his mind. Here we find descriptions of two works of magnitude, the Chirk Aqueduct and that of Pont-y-cysylte.

"The Ceriog, or Chirk valley, is 710 feet in width; the banks are steep, with a flat alluvial meadow between them, through which the river passes. To preserve the canal level, the surface of its water must be maintained at 65 feet above the meadow, and 70 above the water in the river. There are 10 arches, each of which is 40 feet span. The first stone of this aqueduct was laid on the 17th June, 1796. Previously to this time, such canal aqueducts had been uniformly made to retain the water necessary for navigation, by means of puddled earth retained by masonry; and in order to obtain sufficient breadth for this superstructure, the masonry of the piers, abutments and arches was of massive strength; and after all this expense, and every imaginable precaution, the frosts, by swelling the moist puddle, frequently created fissures, burst the masonry, and suffered the water to escape, nay, sometimes actually threw down the aqueducts; instances of this kind having occurred even in the works of the justly celebrated Brindley. It was evident that the increased pressure of the puddled earth was the chief cause of such failures; I therefore had recourse to the following scheme in order to avoid using it. The spandrills of the stone arches were constructed with longitudinal walls (as at Kirkcudbright Bridge), instead of being filled with earth, and across these the canal bottom was formed by cast-iron plates at each side, infixed in square stone masonry. These bottom plates had flanches on their edges, and were secured by nuts and screws at every juncture. The sides of the canal were made waterproof by ashler masonry, backed with hard burnt bricks, laid in Parker's cement, on the outside of which was rubble stone work, like the rest of the aqueduct. The towing-path had a thin bed of clay under the gravel, and its outer edge was protected by an iron railing. The width of the water-way is 11 feet, of the masonry on each side, 5 feet 6 inches, and the depth of the water in the canal is 5 feet.

"By this mode of construction the quantity of masonry is much diminished, and the iron bottom plate forms a continued tie, and prevents the side walls from separation by lateral pressure of the contained water. There being a quarry of excellent flat bedded rubble-stone within a quarter of a mile of the site, and lime-kilns within two miles, the whole, with the exception of quoins, coping and lining the sides of the water-way, which are of ashler masonry, is of rubble work, laid in lime mortar; the materials and workmanship equally excellent. The edifice was completed in the year 1801, and is still in a perfect state; the total cost was £20,898."

* * * * * * *

"About four miles north of Chirk, the aqueduct of Pont-y-cysylte forms a still more striking object than that which I have just described. The north bank of the river Dee at this place is abrupt; on the south sid · the acclivity is more gradual; and here, on account of gravelly earth being readily procured from the adjacent bank, it was found most economical to push forward an earthen embankment, 1,500 feet in length from the level of the water-way of the canal, until its perpendicular height became 75 feet; still a distance of 1,007 feet intervened before arriving at the north bank, and in the middle of this space the river Dee was 127 feet below the water level of the canal, which was to be carried over it; therefore serious consideration was requisite in what manner to accomplish this passage at any reasonable expense. To lock down on each side 50 or 60 feet, by 7 or 8 locks, as originally intended, I perceived was indeed impracticable, as involving serious loss of water on both sides the valley, whereas there was not more than sufficient to supply the unavoidable lockage and leakage of the summit level. To construct an aqueduct upon the usual principles, by masonry piers and arches 100 feet in height, of sufficient breadth and strength to afford room for a puddled water-way, would have been hazardous, and enormously expensive: necessity obliged me therefore to contrive some safer and more economical mode of proceeding. I had about that time carried the Shrewsbury canal by a cast-iron trough at about 16 feet above the level of the ground; and finding this practicable, it occurred to me, as there was hard sandstone adjacent to Pont-y-cysylte, that no very serious difficulty could occur in building a number of square pillars of sufficient dimensions to support a cast-iron trough, with ribs under it for the canal. After due consideration I caused a model to be made of two piers, a set or compartment of ribs, the canal trough, the towing-path, and side-railing, with all the flanches, their nuts and screws and jointing complete. The foundations of the river piers are placed upon hard sandstone rock; those on each bank are either on alternating coal strata, or hard firm gravel. Thus secure of good foundations, suitable sandstone for the masonry, the best of iron, a satisfactory model of the iron work, and able experienced workmen, I proceeded with confidence of ultimate success, although the undertaking was unprecedented, and generally considered hazardous.

"The height of the piers above the low water in the river is 121 feet, their section at the level of high water in the river is 20 feet by 12 feet, at the top 13 feet by 7 feet 6 inches. To 70 feet elevation from the base they are solid, but the upper 50 feet is built hollow; the outer walls being only 2 feet in thickness, with one cross inner wall; this not only places the centre of gravity lower in the pier, and saves masonry, but insures good workmanship, as every side of each stone is exposed. I have ever since that time caused every tall pier under my direction to be thus built. The width of the water-way is 11 feet 10 inches, of which the towing-path covers 4 feet 8 inches, leaving 7 feet 2 inches for the boat; but as the towing-path stands upon iron pillars, under which the water fluctuates and recedes freely, the boat passes with ease. The stone piers are 18 in number, besides the two abutment piers; they were built to the level of 20 feet, and then the scaffolding and gangways were all raised to that level, and the materials being brought from the north bank, the workmen always commenced at the most distant or south abutment pier, receding pier by pier to the north bank; and by thus ascending from time to time in their work, they felt no more apprehension of danger when on the highest, than at first on the lowest gangways; one man only fell during the whole of the operations in building the piers, and affixing the iron work upon their summit, and this took place from carelessness on his part.

"By referring to Plate 11, the general form, and also the details of construction, will be readily understood. This singular aqueduct was opened in 1805, and has now been navigated 28 years with facility and safety; and thus has been added a striking feature to the beautiful vale of Llangollen, in which formerly was the fastness of Owen Glyndwr, but which, now cleared of its entangled woods, contains a useful line of intercourse between England and Ireland; and the water drawn from the once sacred Deva, furnishes the means of distributing prosperity over the adjacent land of the Saxons.

"The whole expense of the aqueduct, and great embankment, was £47,018; a moderate sum as compared with what by any mode heretofore in practice, it would have cost."

Telford had now sufficient standing to recommend him for the execution of great works, and sufficient ability to justify the choice, and we consequently find him employed on the Caledonian canal. This was one of the political lions of the day, and many expectations were formed of the utility of this *national undertaking;* but except forming a fertile source of government and local jobbery and an interminable sink of English money, it has produced nothing but disappointment and disgrace. We shall endeavour to give some explanation of the causes which led to this, and from our own sources point out the reasons for its defeat. To understand the subject better, however, it is necessary that the reader should understand something of the nature of the country, which is explained in the following extracts, describing a singular valley,

"Called the Great Glen of Scotland, which, commencing between the promontory of Burgh-Head in Elginshire, and Cromarty, passes through a succession of sea-inlets and fresh-water lochs (lakes) to the southern extremity of Cantyre, a distance of 200 miles, and in nearly a straight direction between the Naze of Norway and the north of Ireland. The whole of this extensive valley, with the exception of about 22 miles, being occupied by navigable waters, and the excepted space by a navigable canal, saves upwards of 500 miles of dangerous navigation, as compared with that by the Orkneys and Cape Wrath. Ships of war, were this track open to them, might in two days, from a station at Fort George near Inverness, reach the north of Ireland."

The description of the works on the canal is meagre in the extreme, deficient in interest, and destitute of that practical instruction which such immense works might have afforded. Numerous difficulties were to be encountered and overcome, and, as Telford himself observes, the narration of failures often leads to more practical information than the description of success. From the account of the Caledonian Canal we shall give a few extracts, which may serve to explain the comments we have to make thereon.

"About ten miles within Fort George, and one mile to the north-west of the mouth of the river Ness, the tide-way of the Beauley Water is from 5 to 7 fathoms deep, and here, at the fishing village of Clachnacharry, is the entrance of the Caledonian Canal. In order to secure an entrance for vessels of 20 feet draught of water, at the top of neap tides, it was necessary, from the flatness of the shore, to place the tide-lock 400 yards from high-water mark, at the end of an embankment; and in constructing this lock, very considerable difficulties occurred, which will be afterwards described. I shall here only observe, that this sea or tide-lock is 170 feet long in the chamber and 40 feet wide, and that its rise is 8 feet; from this lock the canal is formed by artificial banks, upon a flat mud shore, until it reaches high-water mark at Clachnacharry, where another lock of similar dimensions is placed upon hard mountain clay. Immediately to the south of this, is formed a basin or floating dock, 967 yards in length and 162 in breadth; its area is about 32 English acres. It is furnished with a wharf-wall and warehouse at the south end, and its ample dimensions produced earth by excavation for its own banks, and also for supporting the adjoining locks, instead of having recourse to back-cutting.

"At the south end of this basin, the great north road passes over a swing bridge, and adjacent to it are the four united Muirtown locks, each 180 feet long and 40 feet wide, which together rise 32 feet, lifting the canal to the level of the surface water of Loch Ness, when in its ordinary summer state. From the top of these locks the canal, 50 feet wide at the bottom, 20 feet deep, and 120 feet at surface water, is carried by easy bends in the rear of the insulated hillock of Tomnahuric, to the river Ness at Torvaine, where, by reason of a precipitous bank, the canal is constrained to occupy the former bed of the river, a new channel being made for it by removing the opposite bank, which at the same time produced earth for separating the river and canal; a great work, more than half a mile in length. The same kind of difficulty, but less in extent, is overcome in the same manner twice before the canal enters the small loch of Doughfour, (six miles from Clachnacharry) by a regulating lock 170 feet long and 40 feet wide, actually placed in the old channel of the river Ness, which in this place was heretofore separated into a double stream by an island of gravel. Such a situation points out the difficulty of keeping an extensive lock-pit free from the influx of river water, the ordinary level of which was 20 feet above the necessary excavation. Mr. Davidson's incessant attention was necessary and conspicuous during this unusual operation in the years 1813 and 1814, as well as that of Messrs. Simpson, Cargill, and Rhodes.

"Between the small Loch of Doughfour and the outlet of Loch Ness at Bona Ferry, the river has been deepened, chiefly by a dredging machine. Loch Ness is about 22 miles in length, no where less than a mile in breadth; in depth varying from 5 to 129 fathoms, (a greater depth than is found between the Murray Firth and the Baltic sea,) its direction is straight, with several small bays of moderate depth, affording good anchorage, as at Urquhart, Invermorrison, and Port-Clare, on the north side; and at Dores, the fall of Fyers, and the Horse-shoe on the south side.

"At the south-west end of the Loch stands Fort-Augustus, on the north side of which the river Oich enters the Loch where the canal leaves it, crosses the glacis, and at the back of the village ascends 40 feet by means of five connected locks, each 180 feet in length; from thence it passes along the south side of the river to the north-east corner of Loch-Oich. In this distance of about five miles is the Kytra lifting lock, and a regulating lock, each 170 feet long and 40 feet wide, and the channel of the river has been changed in two places; the breadth of Loch-Oich is inconsiderable and irregular; in some parts it requires deepening by dredging, especially where the river Garry falls in from the north, draining the whole of Glengarry, and having in its course Loch-Garry 6 miles in length, and Loch-Quoich 10 miles; the summit supply of water for the Caledonian Canal is therefore abundant.

"Between the western end of Loch-Oich and the east end of Loch-Lochy, a distance of about two miles, the surface of the ground is about 20 feet above the water level, and the depth of the canal water being 20 feet, there is 40 feet depth of cutting. Near Loch-Lochy are two locks, a regulating lock and a lifting lock; the difference between the surface of the water in these two locks (although Loch-Lochy has been raised 12 feet,) is nearly 10 feet.

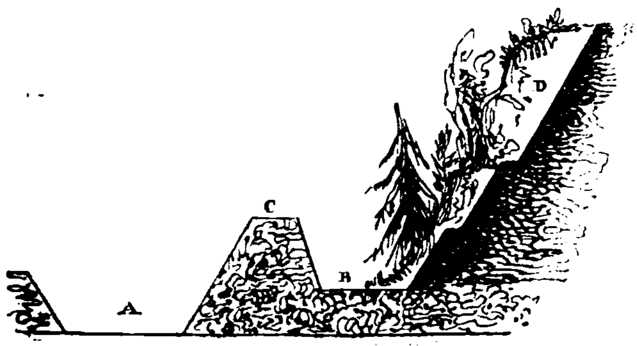
"At the south-west end of Loch-Lochy (which is 10 miles in length) there is a regulating lock as usual, and the canal is carried over rugged ground along the north-west side of the river Lochy, its line intersected by one considerable river, and by several mountain streams; the ordinary level of Loch-Lochy is continued along the canal to within one mile of Loch-Eil, where are eight connected locks, each 180 feet long and 40 feet in width, and together falling 64 feet; from thence the canal is continued on a level to Corpach, where are two connected locks falling 15 feet, and a single sea-lock entering the tideway of Loch-Eil. The sill of this last-mentioned lock was laboriously excavated in rock, so as to ensure a depth of 20 feet of water at high water of an ordinary neap-tide. The operations which were necessary in making this lock were entirely dissimilar, but not much less difficult than those at Clachnacharry, and are worthy of attention.

"The connection with the tideway being to the westward of the general line of the valley, and at the rectangular turn of Loch-Eil towards Fort-William, a well-sheltered roadstead and good anchorage are here obtained. Loch-Eil and the Linnhe-Loch are inlets of the west sea, and the latter joins the usual channel of navigation south of the Sound of Mull.

"The navigation by the Caledonian Canal between the two seas was opened at the latter end of 1823; the eastern district had previously been navigated three years."

From the above description of the works in the neighbourhood of Torvaine the professional reader would be led astray, for no notice is taken of the difficulties which impeded the progress of the works, and which still cause them to remain in a defective state.

To understand this, it must be observed that Torvaine is the name of a very high hill of sand and gravel, at the base of which flows the River Ness, and it was necessary to widen the bed of the river on the south side, which, at the same time, produced earth for separating the river and canal, as stated above, by removing the opposite bank; for in fact, there was no opposite bank to remove, the land on that side being very low and flat; and although the widening was rather considerable, the earth so obtained formed but a small portion of what was necessary to separate, by a proper embankment, the river and the canal. The hill of Torvaine, although at least 150 feet above the river, had to be cut into to a considerable extent, before a sufficient quantity of stuff could be procured and the canal was partly constructed on the hill, and partly in the river. The annexed sketch will better describe the features of the canal at this particular place, and show the peculiar nature of the position.



A—The Ness River.
B—The Caledonian Canal, partly cut out of the foot of the hill, 50 feet wide at the bottom, and 120 feet at the top, and 20 feet deep.
C—Embankment formed from the cutting opposite, with a slope of 1½ to 1, and 20 feet wide on the top, which divides the canal and the river Ness.
D—The part of Torvaine Hill cut away, with a slope of 2½ to 1, and benches 10 feet wide.

The course of the canal from the Muirtown Locks, on towards Torvaine, passes through a stratum of clay, but as it more nearly approaches Tomnahuric and Torvaine, the stratification becomes loose and porous. At Torvaine, in particular, the whole hill is composed of sand and gravel, which continues through the Muir of Dunanchroy, and on to Dochgaveh. The engineers, notwithstanding the knowledge of these materials forming the banks of the canal, neglected taking any precaution to line the canal with puddle, but entirely depended on the great supply of water which they had in the Loch and River Ness, which run close to the canal through nearly the whole district. These, they trusted, would supply the loss of any water by filtration; and they also calculated that, by means of this, the deposit of the river would ultimately have filled up the interstices of the gravel, and that, thereby, the canal would be rendered water-tight. With this impression, no side-lining or bottom puddle was provided, and the consequence was, that they could never keep the canal full, but the water filtered out before it reached Tomnahuric. This circumstance occasioned much surprise and disappointment at that time, and a dam was placed across the canal, to retain a depth of about five feet of water through the Moir of Dunanchroy, so as to try the effects of filtering. Many thousand tons of loamy silt were brought down and hove into the bottom of the canal, but to no purpose; for, as fast as it was thrown in, it was carried through the sides and the bottom into the river; and instead of the silt filling up the interstices, every part of the canal when the water was let in, became more and more porous; for the water not only carried away the stuff thrown into the canal, but it also carried away all the sand and smaller pebbles, making the gravel still more porous, so that in a very short time the bottom and sides of the canal became as open as if it had been made through a mountain of macadamized stone. The contractors were employed for many days near Dunanchroy, trying to prevent the leakage, but without the least practical effect.

There can be no doubt that the want of a puddle lining in this part of the canal was attended with disappointment, great expense, and to a certain extent a failure of what the canal proposed to be, and what it ought to have been conducted on a different plan. Instead of using the porous materials of Torvaine Hill for the embankment, the clay which was found between Torvaine and the Muirtown Locks should have been employed, instead of which it was wheeled into spoil, and thus thrown to waste. The canal ought also to have been cut much deeper and wider, not only to receive the necessary puddle of clay, but also for a sufficient protection of gravel facing to keep it firm. All this could have been done at half the expense, or perhaps one-third, of that afterwards incurred; but the most unfortunate part remains yet to be told. It is a fact, that after having proved the ineffectual and superficial manner in which the canal had been constructed, and having determined to deepen and widen it to the necessary size for receiving a proper thickness of puddle to resist the pressure of water, by some unaccountable error the canal was never made deep nor wide enough for the purpose, and up to this day the canal at that part has not strength of side and bottom lining to carry more than 12 feet water, instead of 20. We ask the editor, is not this the true cause of the failure of the canal, instead of the ridiculous statement set forth in the work before us at page 66? The facts we have stated are quite sufficient to prevent large vessels from navigating this canal, and until the line is made perfect there, it is quite useless to have 20 feet of water in any other part. We recommend strongly that an inquiry should be made to see how far the defect we have pointed out, and any others, might be remedied, so that the canal may be perfected for 20 feet of water throughout, and what would be the cost.

After such an immense sum of money has been expended upon this canal formed on such a grand scale, with its locks of size and depth to carry through a frigate with all her stores, it is worth while knowing why and wherefore no vessels drawing more than twelve feet water can navigate through it. We are of opinion that a comparatively small sum, as compared with what it has already cost, would make this canal a credit to its projector and a source of profit to the country; and, in time of war in particular, its advantages in letting through ships of war and steam boats would confer incalculable benefit, which in a Russian war could not be too highly prized.

To revert to the progress of the work before us, the next object of considerable magnitude and boldness is the formation of the sea lock at the eastern entrance.

Foulston's Public Buildings.

SECOND NOTICE.

Of the buildings here described, that containing the Theatre, Hotel, and Assembly Rooms, is the most important subject in the volume, both on account of its extent, and of the fulness with which it is illustrated. Its principal, or north front, is 270 feet in extent, 70 of which are occupied by its octastyle Ionic portico, which is raised on five steps, and whose columns are thirty feet high. The remaining one hundred feet on each side of this centre, has three tiers of windows (seven in each tier), viz. ground floor, principal, and attic or mezzanine; all of which openings have dressings to them, those of the ground floor and mezzanine *kneed* architraves, in addition to which those of the principal floor have both frieze and cornice. The general appearance is good,—has a certain degree of breadth and simplicity that are sufficiently pleasing; and although it is upon a somewhat lesser scale, this façade very much resembles in its style that of our Post-office here in town, while it certainly cannot be said that the architect was in any degree indebted to the latter building, since it appears that his own was commenced several years before, namely in 1811, the foundation stone having been laid on September 10th in that year.

So far, indeed, from suffering very greatly by a comparison with a structure that is a national work, and one moreover that cost the country upwards of 230,000*l.*, the Plymouth building—and Plymouth, as Mr. Foulston himself tells us, is, though spirited, proverbially poor—need not shrink from it, as in some respects it will gain by such comparison, particularly if we bear in mind its priority of date, and the means placed at the disposal of the respective architects. This difference in regard to means becomes all the more striking, when we consider that the Plymouth architect had to provide a good deal in the way of decoration both in the assembly room and theatre, to say nothing of the various other apartments; whereas the rooms at the Post-office exhibit nothing further than desks and bare walls. We may further remark, that in regard to the windows, their features are far better in the Plymouth building than in the metropolitan one; and while they are less bald and insipid in themselves, they are not squeezed so close together, consequently do not impart to the design that ordinary dwelling-house aspect which, whatever the design may be in other respects, is almost sure to communicate itself to the rest where such openings are too numerous in regard to the space allotted to them. We may further observe, that the style of the façade is very properly kept up in the adjoining fronts, or returns at the ends, whereas in Sir R. Smirke's building very little similarity of character seems to have been aimed at in its different sides. While we admit thus much in favour of what Mr. Foulston has here done, we feel it incumbent upon us also to notice some defects. As he himself, so far from putting forth any claim to originality, is content to forego all commendation on that head, we feel no reluctance in saying that we must withhold it; but it also appears to us, that notwithstanding his professed admiration of Greek architecture, he does not show himself to have imbibed its real spirit, and caught its feeling. The portico exhibits to us an Ionic order, treated with literal correctness, indeed, as regards certain established particulars of detail, but without any artistical expression or effect. Were it not for the capitals of the columns it would be an absolute negation of any distinct order, because as to all the rest, it is marked, not by positive characteristics of its own, but merely by the omission of those which serve to distinguish the orders.

The entablature is of the plainest description, far more so than that of the Doric order, which is the only one, we may observe, in which our modern architects have thought fit to retain any degree of decoration as regards the frieze. Here both the entablature and frieze have a particularly naked, and not a little heavy appearance; and yet, notwithstanding the rigorous economy—not to say poverty—displayed in those parts, statues are introduced on the acroteria. The doors within the portico are, taken by themselves, pretty enough; but although their prettiness, would recommend them as part of a shop front, or something of that kind, it is altogether out of keeping with the character which ought to be kept up in a building of this class. There is, however, one merit in this portico that ought not to be passed over in silence, which is, that instead of being crammed full of doors and windows, there are only three doors, and as many windows over them, placed so as to correspond with the alternate inter-columns in front, owing to which there is an agreeable degree of breadth and repose in the back ground to the colonnade. The ball-room, which is on the principal floor over the great dining-room, is 77 feet by 40, and 32 high to the centre of its segmental ceiling, through which it is lighted from five lunette windows on each side above the cornice, forming *arcs doubleaux* in the curve of the ceiling itself. The Lysicrates example of the Corinthian order is here introduced, in columns placed two at each end on the sides of the room, coupled with antæ behind them; and the capitals of these latter, which are continued each side, so as to divide it into five compartments or inter-columns, are similar to those of the columns themselves. Whether these pillars and pilasters are of scagliola, or painted either in imitation of that material or of stone, is what we are not informed, neither is it said what is the colour of the walls, although a very few words to that effect would have served to remove the uncertainty in which we are now left in regard to what is a matter of some importance in itself. In our opinion too it would have been far more satisfactory had Mr. F., who is so liberal of his illustrations as to gives a representation of the Lysicrates capital and entablature, favoured us with a drawing of one of the compartments of the ball-room, drawn to the largest size his book would allow. In that case we might perhaps have been better satisfied with the design of the panels on the walls, which, as shown in the general section, have a poor, not to say too trumpery look, for they appear to consist of mere lines with sprigs at their angles. Whether they are really such, or raised mouldings, or whether distinguished by gilding from the general surface of the walls, we are unable to judge.

There are many other parts of the interior which, on examining the plan, seem greatly to stand in need of further elucidation, by means of particular sections on a larger scale. A larger section, or rather two or three of the kind, are very much wanted to show the interior of the audience part of the theatre, for, as represented in the general section, it is so small that very little can be made out in regard to it, especially as the mode of engraving here adopted (lithography) is by no means very favourable to neatness and distinctness when the subject is minute.

On the other hand, a greater number of plates than seems altogether necessary—no fewer than twenty are devoted to explaining the carpentry and machinery of the stage—and as very little, if anything, has been before published in this country on the construction of that part of a theatre, and the various apparatus required for effective scenic changes and exhibitions, this work will doubtless afford great assistance to those who may be called upon to execute anything of the kind; but the letterpress explanation to these plates is exceedingly brief indeed, which is the more to be regretted, because it requires some previous familiarity with such mechanism and contrivances in order to comprehend it—at least to judge how far that here shown is marked by any improvement.

At page 7 of our present volume will be found a table of the dimensions of some of the principal theatres, by referring to which the comparative size of the Plymouth one may at once be estimated; for we shall here transcribe the author's own account of it.

"This is the only fire-proof theatre in the country, the whole of the framing for the boxes, corridors, &c., being of cast-iron. The roof (the span of which is 60 feet) is of rolled iron, and though no piece is more than $\frac{1}{16}$ of an inch in thickness, it is yet remarkably strong, and not more than half the weight of a timber roof. The particular construction of the ironwork to the boxes and the roof is shown in plates No. 41 to 45.

"The auditory is included within a circle, the ends of the boxes being rounded off at three-fourths, and their back partition continuing to the columns of the proscenium, by which there is a perfect view of the stage for the spectators, to the depth of 25 feet from the least eligible seat in the boxes. The pit, which is 33 feet in diameter, will afford accommodation for 200 persons. There are two circles of boxes, capable of receiving 512 persons, and above them a gallery and slip boxes, which will jointly contain 480 persons. By means of an arched colonnade, continuing along the gallery and the slips, the ceiling of the theatre is completed in a perfect circle."

The other dimensions are as follows: the diameter across the boxes, 48 feet; width of curtain, 28; depth of stage from curtain, 30; height from floor in centre of pit to ceiling, 40.

Almost adjoining the preceding building, or separated from it only by a street on the west side of it, is another edifice of Mr. Foulston's, namely the Athenæum, which was begun in 1818. Its north front, or that on a line with the hotel, is a Grecian Doric tetrastyle, and though somewhat lower than the other, is of a richer character, for in addition to the usual ornament of the frieze, the pediment is filled with sculpture, at least is so represented both in the view and elevation, and is surmounted by a figure on its apex. Within, this portico has only a single door below, and three windows above, or rather a window-niche, over the door, with a statue, and a window on each side of it, which arrangement gives some originality and play to the composition. As to the details of the order, which occupy two out of the six plates devoted to this subject, we could very well have spared them, and should have been better pleased to find the various parts of the interior more fully represented. Of the remaining designs we must defer speaking till next month, when we shall pass them in review, and examine how far Mr. Foulston has been successful in his attempts with other styles.

Isometrical Perspective. By T. Sopwith. Weale. 1838.

This is a new edition of Mr. Sopwith's well-known work of Isometrical Perspective, in which he has extended its application to mining. In this department it appears well calculated to be useful equally for professional purposes, as to explain the subject to persons generally interested in it. Mr. Sopwith has introduced several improvements in principle into this edition, and altogether it presents one of the most valuable works which has yet been published on this subject.

The Universal Calculator. By J. Wallace. Glasgow, M'Phun. 1838.

This is the cheapest work on the subject which has yet been published, and has condensed in the smallest possible space, most of the arithmetical knowledge necessary to the engineer. Most of the calculations are made by logarithms, and many new processes of calculation suggested by the able compiler. Altogether it is a work recommended by its portability and the moderation of its price.

LITERARY NOTICES.

We have an article prepared on the subject of *Engineering Education*, but we regret that the pressure of matter has obliged us to defer its publication until next month.

We shall next month refer to Mr. Hay's work on *Colour as applied to internal Decoration and House Painting*.

Loudon's highly interesting work, *The Suburban Gardener*, we shall review in our next number, for in our present crowded columns we should not be able to do justice to it.

We are happy to find that the sister Arts, Painting and Sculpture, have now

a periodical devoted to them under the title of the "Art-Union," the first number of which has been transmitted to us.

We have had placed in our hands the correspondence between Mr. Hyde Clarke and the West Cumberland Railway Committee, but it is too long for our pages, although we think that Mr. Clarke has not been treated with proper attention.

PROCEEDINGS OF SCIENTIFIC SOCIETIES.

INSTITUTE OF CIVIL ENGINEERS.

ADDRESS OF JAMES WALKER, ESQ., THE PRESIDENT,

To the Annual General Meeting, January 15, 1839.

I thank you very sincerely for the manner in which you have expressed yourselves of my endeavours during the past year. It is truly gratifying to me if, through your partiality, I have been at all the instrument of forwarding this institution, and the object of the excellent man (Telford) whose picture is now behind me.* * *

There is really so much doing in this country alone, that without drawing largely upon genius, it would be sufficient to register but a proportion of the new works in progress to keep us fully employed; and surely the most timid associate or graduate need not be afraid of assisting in this. By the original by-laws a candidate for admission was required to present a drawing or paper; this has been waived, but still I consider the claim remains as almost a debt of honour, and the discharge of it would be found agreeable, if set about; agreeable not only in the execution, but in the anticipation of reward; and I would have gentlemen only reflect upon the subjects for which premiums have been adjudged, to see that the distinction requires no particular skill, but only resolution and moderate application; where there is the will, I am sure there is in this case an easy way. I am aware of the difficulty that frequently arises from indecision and in choosing a subject; a difficulty often felt and confessed by our most distinguished English essayist. To remove this, the council have given subjects for papers; and it has occurred to me that it might even be desirable to charge individuals with particular subjects---thus not only imposing more specially a duty upon the individual, but confining his attention to the particular subject (and even to limit the time)---both of which, I have found, from long experience, the best preventives to wandering and procrastination.

Let us remember also, that as the importance of our profession is increasing, and is being felt, it behoves us to exert ourselves to maintain our relative station. Classes, with professorships, for the education of the civil engineer, are established at our colleges; and there is now upon the table a prospectus for the establishment, on a large scale, of a college for civil engineering.

We have every reason to be grateful for our success heretofore, but our motto must be "Forward," and we must keep up to it. There is an ample harvest to reap from the new works which are going on throughout this country, from the Land's End to the northern extremity of Scotland, and in Ireland; and as the powers of human invention and discovery increase, the range for it becomes more ample---the higher we rise, the more enlarged is the sphere that bounds our prospect. There is reason to believe, from analogy, that we know as yet but a small portion of the powers and capabilities of matter, and which require but the application of mind to bring them to light. Much, I admit, has been done within the last century; but as our deepest pits are, when compared with the radius of the earth, but scratches on the surface, such, I believe, would our stock of knowledge, much as we think of it, appear to a mind that could comprehend all the properties and beauties of nature, even of that province with which the civil engineer has to deal; and this would appear the case to the last of a succession of Newtons, or Watts, or Huddarts, supposing each to add to the stock of his predecessor, even more strongly than it does to us. How much then ought we to admire that beautiful adaptation, which is fitted to man in every stage of his mental improvement! I sometimes doubt whether, when mechanical and other scientific improvements are made, we are disposed sufficiently to refer to nature, and then to rise to the author of Nature, in admiration of the treasures which have been opened, and are still in store for mankind. Thus, in admiring the genius of a Newton, and others, we are not so disposed as we ought to be to carry our admiration back to the natural substances which have produced the glass, without which the principal phenomena of light would still be unknown; and to reflect, that these substances have existed from the beginning, although their combinations are of human discovery of no very ancient date. Again, when we admire the stupendous fixed or the active locomotive engine, or the fine machinery of Huddart, for drawings of which you have seen two premiums awarded, and reverence the minds which have brought these to their present state, let us not forget how small are these compared with the materials for steam and for manufacturing the steam-engine,---the water, the coal, and the iron; how insignificant these minds compared with the mind which gave to them the properties they have,---to steam its elasticity and wondrous velocity,---and impressed upon matter those beautiful and uniform laws which govern it, and enabled a Huddart to calculate with certainty the strength of his materials, and what would be the result of his complex combination of wheels and pinions! What the poet said of the undevout astronomer, that "he is mad," may apply with equal truth to the undevout mechanic or engineer; and it would be well if those delightful feelings were cultivated, and invariably associated with the study and practice of the engineer, so that his mind might in every pursuit dwell upon the wondrous adaptations of nature to the wants and pleasures of the community, and both in its lowest and most improved state be led to the contemplation of the power which formed, and the goodness which so admirably fitted the whole for the use of his creatures.

I have been led without premeditation into this train of reflection. I gratefully acknowledge the attention you have paid to me on the present and on every occasion, and now leave the chair with a repetition of my thanks for all your kindnesses.

Jan. 8.—The PRESIDENT in the chair.

The discussion on this occasion was on the use of peat in the manufacture of iron. It had been remarked at a previous meeting that the iron made with peat fuel was more malleable than Swedish, and that the tools were of a superior quality. It was doubted whether peat fuel had been recently employed, or, indeed, whether it could be used at all in the puddling furnace, though it might in the refining or smelting furnace, but with a diminished produce. The working of iron by peat fuel was known to improve its quality in some respects, and the welds especially thus made were superior to those made with coal. The Dartmoor peat was frequently used for this purpose, and found exceedingly good. The improvement of iron by the use of a particular fuel seemed a very difficult question. The weld made with ligneous carbon, owing to the absence of sulphur and pyrites, must be better than that made with a fuel containing these impurities. The analysis of peats is very various. They all contain 5 per cent., and some 20 per cent., of earthy matter. Some kinds of peats were stated to produce three times as much gas as coal. Peat was said to contain no sulphur, but the experience of several gas-works, in which peat was employed, proved that some peats contain large quantities of sulphur, as the purifiers become rapidly filled with sulphuretted hydrogen. All coal, however pure to the eye, contains pyrites and sulphur, so that sulphur must be considered as one of the elements of coal. Much is to be attributed to long practice in the use of fuels; the smiths of Cornwall can use peat, and the smiths of Pembrokeshire anthracite, for all purposes of working iron: both would, however, use pit coal could it be conveniently procured.

Jan. 29.—BRYAN DONKIN, V.P., in the chair.

On framing Lock Gates without Iron-work, by S. BALLARD, A. Inst. C.E.

The horizontal pieces in gates thus framed are held to the back by dovetailed tenons and wedges; the use of iron T pieces being thus wholly dispensed with, the premature decay which invariably takes place where wood is in contact with iron is entirely avoided. The mortices into which the pieces are inserted are previously filled with tar, or white lead, and on the wedge being driven in, every part is rendered perfectly water-tight. This method has been adopted in gates on the Herefordshire and Gloucestershire Canal, and, after eight years' experience, found completely successful.

On Tubing the Boilers of Locomotive Engines, by G. BUCK, M. Inst. C.E.

The author's object has been to determine the diameter of the tubes of a locomotive boiler, so that the greatest quantity of steam may be produced by a given quantity of fuel, on the condition that the evaporating effect of the hot air, in passing through the tubes, is in proportion to the extent of surface in contact with the hot air and the time of contact conjointly. The result of this investigation is, that the distance betwixt the diameter of two adjacent tubes should be equal to four times the interval between their internal surfaces. On comparing the aggregate surface of a locomotive boiler tube, in this proportion, with those generally employed, the former is superior by from 23 to 26 per cent. to the latter.

On the state of the Suspension Bridge at Montrose, after the late Hurricane, with remarks on Suspension Bridges, by COLONEL PASLEY, Hon. M. Inst. C.E.

The hurricane of the 11th of October carried away a third part of the roadway of the suspension bridge at Montrose, and broke or bent very much all the rods on the west side. From the effect here produced, and his experience of the motions of suspension bridges, the author is of opinion that the dangerous undulations are longitudinal; that the whole roadway is brought, by the action of the wind or pressure of the air beneath, into a state of waves, by which the roadway is ultimately broken up; that this can only be obviated by adopting a strong longitudinal trussing, as has been done by Mr. Tierney Clark in the Hammersmith Bridge, in which no motions of this nature are experienced, even in the most violent gales. This opinion of the action of the wind on the under side of the roadway, is confirmed by what Colonel Pasley once witnessed at Chatham Dockyard. One side of the roof of a large ship-building shed rose up and down repeatedly, flapping like the leaf of a book, until a portion, of about the extent of 40 feet by 40, was floated up like a sheet of paper, and carried to a distance of 50 yards.

Feb. 5.—The PRESIDENT in the chair.

The following gentlemen were elected:—Alfred Burges, John Taylor, as Members; Joseph Baxendale, J. M. Parsons, J. Bennett, as Associates; and Charles Wood, M.P., as an Honorary Member.

Mr. C. W. Williams presented specimens of Peat, from the first state, as taken from the bog, to the last, when compressed and converted into a hard coke; and of his new Resin Fuel, or artificial coal, which is composed of resin and turf coke. This resin fuel is found of the greatest use in long voyages, when used with a proper proportion of coal, as it enables the fireman to maintain the requisite pressure of steam with great regularity, and also to raise steam more rapidly on any emergency. It is not adapted for use as a fuel by itself, but when about 2½ cwt. of this fuel is used with about 20 cwt. of coal, by throwing it in front of the fire with each charge of fresh coal, a much better combustion of the coal takes place, and the effect is equal to that which would be produced by 27 cwt. of coal. Thus 2½ cwt. of this fuel so employed is equivalent to 7 cwt. of coal. The cost is from 35s. to 40s. per ton. The Transatlantic steamers carried from 40 to 60 tons of it, and besides the advantage attending its use, there was a saving in room, which was applicable to the stowage of cargo.

A long discussion took place on the important facts which the application of this fuel had elicited. These appeared in some measure contradictory to the results, which could not be doubted, that 9 lb. of coke will do as much in any department of the arts as 12 lb. of coal: for on adding to coal a peat and a hydro-carbon far more inflammable than coal, the result is equivalent to that which is produced by all the carbon, hydrogen, and oxygen, in many times the quantity of coal. It was remarked, that the circumstances under which fuel was employed ought to be considered, as the consumption of fuel under steam-boilers could hardly be compared with the consumption for simply heating and keeping hot a large mass of matter as in a glass-house. It could not be believed, that the absolute quantity of heat from the coke of a ton of coals is the same as of the ton of coals, for in that case all the heat of a coke oven would go for nothing, and there were instances of this being beneficially employed.

INSTITUTE OF BRITISH ARCHITECTS.

Feb. 4.—P. F. Robinson, V.P., in the chair.

The Cavalier Bianchi was elected an Honorary and Corresponding Member.

The report of the Council, as to the adjudication of the Prize for the best restoration of an ancient castle, was read and confirmed; and the letter, bearing the motto of the successful drawings, having been opened, the author appeared to be Mr. Samuel Sharp, Associate, of York. In consideration of this being the second time that Mr. Sharp had entitled himself to the approbation of the Institute, for the zeal and talent with which he had executed the restorations of St. Mary's Abbey, York, and Sheriff Hutton Castle, it was resolved that a gold rim be added to the Soane medallion, which will be awarded to him.

A translation, by Mr. Donaldson, *was read, of a memoir of the late* M. Percier, *architect, of Paris, Honorary and Corresponding Member, forwarded by* M. Vaudoyer, *architect.*

Charles Percier was born at Paris of a respectable family, and received a liberal education. From his earliest age he evinced a talent for drawing, was placed by his father at the free school for drawing, then under the management of the founder, M. Bachelier, painter to the king. His taste leaning to the side of architecture, he soon after entered the studio of M. Paris, whose school had long enjoyed considerable reputation. In 1783, M. Percier carried off the second great prize; and in 1786, having gained the first great architectural prize, he became a travelling student to the French Academy at Rome. He there became the companion and intimate friend of M. Fontaine, who, possessing like tastes, like ardour, and like information, entered with him into the same branches of study, and from that time the two friends worked together, travelled together, and lived in the same dwelling; and, till they were separated by death, they shared the same glory, the same joys and sorrows. On the return of MM. Percier and Fontaine to France, the storm of 1792 was raging, and they employed their talents in designing for manufacturers of carpets, paper, furniture, &c. It was at this time, also, that they engraved and published their many useful studies in Italy. A calm having at length succeeded, M. Percier's talents began to be appreciated under the Emperor, and in the following reigns he was called to assist in great works. Le Carrousel, the Triumphal Arch, the interior of the Tuileries, the Rue de Rivoli, the completion of the Louvre, Le Chapelle Expiatoire, the improvements of l'Elysée, de Malmaison, de Neuilly, and Fontainebleau. M. C. Percier died on the 5th of September, 1838, at the age of seventy-four. He was a man of great general information, conversant with the literature of his own and foreign countries, well informed in history, antiquities, a lover of painting and of music, to all of which he had devoted much attention. In consideration of the advantages he had in his youth derived from the Royal Free School of Design, M. Percier bequeathed a sum of 150,000 francs to this institution, for the encouragement and assistance of poor and deserving students. At the conclusion of the paper, Mr. Donaldson reviewed at some length the various merits of the numerous works published by Messrs. Percier and Fontaine.

At an Ordinary General Meeting, held at 16, *Lower Grosvenor-street,* 18*th Feb.*, 1839, P. F. Robinson, V.P., *in the Chair.*

A letter was read from Mons. Vaudoyer, acknowledging the thanks of the Institute for his former communication, and enclosing a list of the restorations made by the students of the French Academy at Rome, and preserved at the Academy of Fine Arts, at Paris.

The following donations were announced as having been received since the last meeting:—

From Mons. Laves, Hon. and Cor. Mem. at Hanover: A Print of the Waterloo Column and Hall of the Knights, Hanover; and Pamphlets on the Qualities of Woods.—George Saunders, Esq.: two steel standard foot measures, prepared by Ramsden.—H. E. Kendall, Fellow: Cast of the Lion's Head, from the Parthenon.—C. J. Richardson, Fellow: Proof impression of a view of Holland House.—T. L. Donaldson, H.S.: one volume of Transactions of American Institute, containing the questions published by the R. I. B. A.—W. C. Mylne, Fellow: Editio Princeps of Vitruvius, and Autograph Letters of G.B. Piranesi, Bonomi, Robert Mylne and Lewis, Architects; and of Sir William Hamilton, formerly British Ambassador at the Court of Naples.—Copy of Resolutions of Associated Architects, to consider cases of frequent fire and means of prevention.—Thomas Chawner, Fellow, presented twenty guineas.

A paper was read from Mr. Martin, of Derby, describing a new species of cement invented by him, accompanied by specimens.

A paper was read by John Shaw, Fellow, on Ecclesiastical Architecture applicable to Modern Churches; a printed copy of which Mr. Shaw also presented.

A Description of the Manufacture of Paper Hangings, by Mr. John Gregory Crace, was read; illustrated by various samples of papers, and explained by specimens executed by Mr. Crace's assistants at the time.

A Letter was read from Wm. Wilkins, Esq., R.A., addressed to his Lordship, the President, calling attention to some drawings which accompanied the letter, made by a young self-taught draughtsman at Cambridge. The letter also stated that another volume of the Dilettanti would soon be ready for publication.

ARCHITECTURAL SOCIETY.

Ordinary Meeting of the Society held 29th January, 1839.—William Barnes, Esq., in the chair.

Michael Meredith, Esq., of Blomfield-street, Finsbury Circus, was elected a member.

The Chairman announced a donation of twenty guineas, by J. Griffiths, Esq., (member,) of Finsbury-place, South.

Monthly Meeting of the Society held Tuesday evening, the 12th February, 1839.—William Tite, Esq., President in the chair.

Thomas Nichols, Esq., of Castle-street, Holborn, was elected a Member.

E. W. Brayley jun., Esq., delivered a Lecture "On Limestones and other substances affording materials for Cements," being the second of a course of lectures now in progress of delivery in the Society's Rooms.

The Chairman announced that the subject for the sketches proposed to be produced by the student members at the next meeting was as follows:—"The elevation and plan of an entrance to a Lunatic Asylum, detached with lodges each side."

The next Public Meeting will be held on Tuesday evening, the 12th instant, when Mr. Brayley will deliver his third lecture "On artificial substances employed as substitutes for Stone."

ROYAL SOCIETY.

Feb. 7.—The Marquis of Northampton, President, in the chair.

James Heywood, Esq., and the Rev. H. Mosely, M.A., were elected fellows.

A paper was read, entitled, '*Notice of a Shock of an Earthquake, fell in the Island of St. Mary's, one of the Scilly Islands, on the 21st of January,* 1839. *By the Rev. George Wordley.*'

The tremulous motion of the ground is described as being very slight, and felt chiefly in the south parts of the island. It was accompanied by a peculiarly harsh and grating sound, which was only of momentary duration, and no particular agitation of the sea was observed.

A paper was also read in part, entitled, '*Observations on the Parallel Roads of Glen Roy, and of other parts of Lochabar, with an attempt to prove that they are of marine origin,*' by Charles Darwin, Esq., F.R.S.

Feb. 14.—J. W. Lubbock, Esq., V.P. and Treas., in the chair.

A paper was read, entitled, '*Researches on the Chemical Equivalents of certain bodies,*' by Richard Phillips, Esq., F.R.S.

The author examines, by a new series of experiments, the truth of the theory of Dr. Prout and Dr. Thomson, namely, "that all atomic weights are simple multiples of that of hydrogen"—a theory which the late Dr. Turner had maintained is at variance with the most exact analytic researches, and consequently untenable. Although the experiments of Dr. Turner, and the inferences which he drew from them, agree very nearly with those of Berzelius, it still appeared to the author desirable to investigate this subject; and it occurred to him, that the inquiry could be conducted in a mode not liable to some of the objections which might be urged against the processes usually employed. Dr. Turner having adopted a whole number, namely, 108, as the equivalent of silver, this substance was selected by the author as the basis of his inquiry into the equivalent numbers of chlorine, and some other elementary gases. It appeared to him, that the chance of error arising from the fusing of the chloride of silver might be entirely removed, and other advantages gained, by experimenting on silver on a large scale, with such proportions of the substances employed as were deemed to be equivalents, and instead of calculating from the whole product of the fused chloride, to do it merely from the weight of such small portion only as might arise from the difference between theoretical views and experimental results. The author concludes, from the train of reasoning he applies to the series of experiments so undertaken, that no material, and even scarcely any appreciable, error can arise, from considering the equivalent numbers of hydrogen, oxygen, azote, and chlorine, as being 1, 8, 14, and 36 respectively.

A paper was also read, entitled, '*Some Account of the Hurricane of the 7th of January, 1839, as it was experienced in the neighbourhood of Dumfries,' in a letter addressed to* P. M. Roget, *M.D., Sec. R.S., by* P. Garden, Esq.

After describing the position of his house, and the nature of the instruments employed for observation, the writer gives his observations of the barometer and thermometer on the 6th and 7 of January last, and proceeds to state, that on the 6th, at about ten minutes past ten o'clock, P.M., violent squalls commenced, at first with intermissions of perfect calms, but gradually becoming more frequent, and being accompanied by the sound of strong and increasing whirlwinds. By eleven o'clock, the wind was observed to proceed from the east, and its velocity was estimated at forty miles an hour. Its violence then increased, and threatened to blow down the chimneys. At midnight it abated, at the same time shifting to the south or west. At two o'clock in the morning, nearly two tons of lead were torn away by the wind from the west-end platform on the house-top, and thrown down behind the house in a westerly direction. Some of the lower windows having been left a little open, the wind thus admitted into the house forced up and blew off the very heavy hatch door of the roof, which was covered with lead. The whole house rocked terribly, and even the stone floor of the half sunk kitchen story heaved as if shaken by an earthquake; the slates from the roof were blown in every direction, some being carried to a prodigious distance. During the greater part of the night the rain fell in tremendous torrents. In the interval from two to half-past three in the morning, the barometer sunk very nearly an inch and a half, and reached its greatest depression. But the tempest continued till about four o'clock, when it began gradually to subside. Extensive devastation occurred among the trees; some that were blown down raising two or three tons of clay soil with the roots. Several trees thus thrown down fell with their tops to the W.N.W. The writer concludes, from these and other observations, that the first and squally part of the storm began from the E.S.E., and blew from S. by W. at about midnight, and that most injury was done to the slating and roof when the wind was not far from the south. It then gradually veered to the west, till noon, and reached the N.W. point by eight o'clock in the evening of the same day.

Feb. 21.—J. G. Children, Esq., V.P., in the chair.

Captain Arthur Conolly, and Lieut.-Col. W. Reid, C. B., were elected fellows of the Society.

The following papers were read:—

1. 'An Account of the Processes employed in Photogenic Drawing,' in a letter to S. H Christie, Esq., Sec. R.S., by H. Fox Talbot, Esq., F.R.S.
2. 'A Description of an Hydro-pneumatic Baroscope,' by T. J. Cooper, Esq.
3. Continuation of Mr. Darwin's paper 'On the Parallel Roads of Glen Roy, and other parts of Lochabar.'

THE ROYAL IRISH ACADEMY.

January 14, 1839.—Sir W. R. Hamilton, A.M., President, in the Chair.

His Grace the Archbishop of Dublin, V.P., having taken the chair *pro tempore*, the President communicated to the academy the first part of his researches on the Dynamics of Light.

William Bald, Esq., *Civil Engineer,* read a paper entitled *"An Account of the Survey and Map of the County of Mayo."*

The author commenced by giving a brief account of the origin and progress of the construction of topographical maps in Europe. In modern times, the first attempt at the construction of topographical maps may be dated from the seventeenth century, and was due to the Swedes. Under Charles the Ninth, a surveying department was organised, placed under the direction of Buræus, and particularly encouraged by Adolphus. In 1684, the Swedes had completed the general topographical map of Sweden; but it was kept secret, and at the end of a century, they had only published some parts of it. These maps were constructed for the purpose of ameliorating the condition of several provinces of the kingdom, which had been desolated by war. The Dutch also commenced early to construct topographical maps.

The measurement of many arcs of the meridian to determine the figure of the earth, had very much extended geodetical operations, and had, in many cases, become the elements on which topographical maps were based. The numerous geodetical surveys called into activity the inventive powers of the ablest artists in Europe, and instruments of extreme accuracy were produced; and the skill of observing and determining angles kept pace with those improvements connected with this important branch of science. The repeating principle due to the celebrated Tobias Meyer, gave birth to Borda's circle of repetition about 1789, an instrument which has been connected with the most brilliant scientific operations which adorn the annals of the eighteenth century.

Mr. Bald then showed to the academy some specimens of the new map of France, and noticed briefly the trigonometrical survey of England—the Down survey of Ireland—the maritime surveys of Ireland—the county surveys, and the bog surveys. He made some observations on the great importance of accurate maps, especially to professional men engaged in conducting public works, such as roads, canals, river navigations, harbours, railways, supplying towns with water, irrigations; to the geologist and miner, exploring the strata, and mineral wealth of the country; to the statesman devising improvements, and developing its resources; and to the poor, by affording useful employment to the working classes.

The author then alluded to the map of Egypt, which was made during the period it was under the dominion of the French republic, and which received from Bonaparte all that protection and assistance, which so much distinguished him on all occasions regarding the advancement of the works of science. This map was engraved on fifty-three sheets of copper, and the names are engraved both in Arabic and French.

After this introductory account of the rise and present state of the topographical art, Mr. Bald proceeded to the details connected with the survey of Mayo.

The instruments used in this survey were a seven inch theodolite; two five-inch theodolites, by Troughton; a small theodolite, by Dollond; and also a five-inch one by the same artist. In taking the levels over the bogs, two of Troughton's best levels were used. The barometers were made by Mr. Thomas Jones, of London. There were also two plain tables, a chain for measuring base lines, a sextant four inches radius, and two sextants, each ten inches radius, divided to ten seconds for observing altitudes, one of which was made by Troughton.

The proceedings of the geometrical details of the survey were then given, and the mode of describing the rise and fall of the ground, which was shaded on the map with a depth of colour corresponding to the sines of the angles of inclination. The irregularities of surfaces were simply delineated by hatching lines, drawn in the direction of the declivities, forming a series of normals, perpendicular to the horizontal lines of equal level.

Dr. Smith read a paper (by Lieutenant Newenham, R.N.) *"On a Tumulus or Barrow, near Rush, County of Dublin."*

The barrow, called Knocklea, or the Giant's Hill, is situated on the edge of the cliff, about midway between the village of Rush, county of Dublin, and the martello tower to the northward, called Dromanick, and immediately in front of Sir William Palmer's residence, Kinure Park.

It appears to have been composed of quantities of boulder stones and earth heaped up into a conical form, and sloping away to the base, which was square, as appears from the eastern angle, which yet remains perfect. Within the base of the mound there was a circle formed of large stones placed on their ends, and about one hundred paces in circumference.

The farmer who rents the land on which it stands has removed about one-half of the mound, for the sake of the earth as a manure, and nearly one-half of the circle of stones on the south side, for the purpose of building a wall, part of which is erected on the stones forming the western side of the circle. In the course of his depredations he discovered a passage which opened on the south side;* its entrance was funnel-shaped, and the walls of this passage were formed of flag-stones placed on their ends, and roofed in with the same. It was about eleven yards long, and one in width; and led to a low chamber about eight feet long, and six wide, which was situated nearly in the centre of the barrow, and formed of stones in the same manner as the passage.

The farmer removed all the stones forming the western side of the passage, and in the course of his excavations found some human bones on the south side of the chamber, and within the circle of stones. The lines of stones forming the sides of the passage appear to continue on through the mound towards the north side; and a few feet below the present surface of the barrow, a little to the north of the chamber, there is a bed of periwinkle shells, about eight inches thick, with some limpet and muscle shells intermixed; and beneath this bed of shells there is a quantity of rich dark mould, with some reddish earth, which has the appearance of being burned. A few human bones, and some bones of small animals, were found in the earth beneath.

Outside the circle of stones, and on the very edge of the cliff, near the western angle of the mound, there was found a rudely-formed grave containing a human skull, with the bones of the arm, leg, and thigh, which apparently had never been disturbed; the bones of the back, ribs, &c., could not be discovered.

There are several remains of entrenchments and smaller mounds in the neighbourhood.

Circles of stones are found enclosing many similar barrows in Ireland. At New Grange, near Dowth, in the county of Louth, the circumference of one measured about four hundred paces; and in a barrow near Drogheda, an engineer officer found a gigantic skeleton, a pair of elks' horns, and a spear, in an upright position: the horns were above the skeleton. There are many barrows in the neighbourhood of Drogheda, which, if opened under the direction of competent persons, would probably lead to many very interesting discoveries.

The President gave an account of a singular appearance of the clouds, observed on the 16th of December, 1838, at the Observatory of Trinity College, Dunsink. They appeared, for at least the last four hours of day-light, to be arranged in arches which converged very exactly to the N.E. and S.W. points of the horizon; while the breaks or joints in these arches were directed, though with less exactness, to two other horizontal points, which seemed to be always opposite to each other, but ranged from N.W. and S.E. to N. and S. Conjectures were offered with respect to the cause of this appearance.

SCHOOL OF DESIGN,

MARGARET-STREET, CAVENDISH-SQUARE.

We are happy to witness the progress of this excellent institution, which under its able conductor, Mr. A. de Villalobos, seems to effect all the purposes

* Mr. Newenham thinks that, as far as his observation has extended, the entrance of all barrows is on the south side.

for which it was originally designed. In addition to the excellent system of instruction, and the valuable collection of the antique, Lectures on Anatomy have been commenced, and form an additional attraction, if any were needed.

MEETINGS OF SCIENTIFIC SOCIETIES FOR MARCH.

Royal Society, Thursday, half-past eight, P.M., 7th, 14th, and 21st.
Society of Antiquaries, Thursday, eight, P.M., 7th, 14th, and 21st.
Institution of Civil Engineers, 25, Great George-street, West, Tuesday, eight, P.M., 5th, 12th, 19th, and 26th.
Royal Institute of British Architects, 16, Grosvenor-street, Monday, eight, P.M., 4th and 18th.
Architectural Society, Tuesday, eight, P.M. 12th.
Society of Arts, Wednesday, half-past seven, P.M., 6th, 13th, 20th, and 27th.
Ditto, Illustration, Tuesday, eight, P.M. 12th.
Geological, Wednesday, half-past eight, P.M., 7th and 21st.
Royal Geographical, Monday, nine, P.M., 11th and 25th.
Graphic, Wednesday, eight, P.M. 13th.

ROYAL EXCHANGE.

We regret that we cannot yet announce any final decision in regard to this building. The disgraceful delay which has now arisen in consequence of the dispute between the City and Government will be the cause of losing the very best time of the year for getting in the foundations of the building. If the city authorities were to determine to-day to issue notices to architects for the designs, there must be a delay of at least three months, to give them an opportunity of working out their ideas, and at the end of that time after the committee should have determined upon the design to be adopted, there must be a farther delay of another three months for the preparation of the contract and working drawings, specification and estimates for the builders, which would bring us to the autumn, and drive the builder into the short day and the inclement season. As there cannot be any difference between the parties as to the necessity of clearing away the immense quantities of rubbish and the old foundations for the new building, we should recommend to the city the necessity of immediately engaging with a contractor for that purpose, which will be very considerably forwarding the works.

For our part we cannot see for what reason the city should be afraid of submitting the selected design to government. If all is "to be fair and above-board," and if the city really intend to submit the designs to public competition, and select the best without *favour or affection for any party*, there can be no fear that the government will act in opposition to the city, when thus so honourably calling upon the profession for their labours. We do hope and trust that before our next Journal is published, some decision will have been made and this vexatious delay arrested.

THE FINE ARTS.

THE NELSON MONUMENT.

On Saturday the 25th ultimo, a highly respectable meeting of the general committee was held at the Thatched-house, St. James's-street, to receive the report of the sub-committee, who were appointed to recommend to the consideration of the general committee those models and designs which were sent to Rainey's gallery, Regent-street, for the Nelson monument, and also to adjudge to the three best the prizes of 200*l*., 150*l*., and 100*l*. Amongst these present we observed Lord Minto, the Marquis of Northampton, Sir John Barrow, Mr. Rice, the Marquis of Breadalbane, Lord Melville, Lord Yarborough, the Earl of Hardwicke. Sir Thomas Troubridge, the Right Hon. John Wilson Croker, Sir George Cockburn, Lord Colchester, the Hon. Captain Grey, Sir George Murray, Lord Hotham, and numerous other persons of distinction.

In the absence of his Grace the Duke of Wellington, the Marquis of Northampton was called to the chair. Mr. Scott, the secretary, then read the resolution of the general committee, appointing the sub-committee, declaratory of their power to recommend which of the models and designs were entitled to the prizes. There were in all 118 drawings, and 41 models. The report stated to design No. 81 they recommended the first prize, that of Mr. Railton, being a column of 174 feet, surmounted by a statue of 17 feet. The committee, however, expressed an opinion that they thought on a column of such an altitude that the features and character of the statue would be lost, and they therefore were of opinion that a statue executed in marble, placed under the shelter of the National Gallery, or some other public building open to the public, was the most appropriate way to evince a country's gratitude. The report further stated, that the model No. 10, of Mr. G. H. Bailey, was entitled to the second prize, and that of Messrs. Fowler and Siever was entitled to the third prize. The secretary thought it fair to state, that between the second and third prizes there was a diversity of opinion amongst the committee on their respective merits.

The Hon. Captain Grey objected to the confirmation of the report as regarded the prizes, as many members of the committee had not seen the designs and models; and out of a committee of upwards of 140, not more than 37 had been to view them. He therefore proposed the consideration of the report should be adjourned for a fortnight, so as to afford an opportunity to the committee to inspect them.

Sir G. Cockburn was willing to consent to an adjournment, particularly as his Grace the Duke of Wellington was absent, who had taken so great an interest in the business.

After a desultory conversation between several members of the committee, a resolution was proposed by Mr. Rice, and seconded by Lord Minto, "That the public, in the week after next, might obtain cards of admission to view the Models and designs in Rainey's gallery, by application to the secretary or any member of the committee."

[We sincerely hope that the committee will delay finally fixing the choice of the models or drawings for the three prizes until after the exhibition of the whole of the Designs has been open to the public inspection, as by this means a tolerable correct opinion may be obtained as to the feelings of the public on the decision of the committee. It appears, however, to us rather out of place that the committee should have selected a design for the first prize, and at the same time think it unsuitable for that situation which has been almost universally admitted to be the best, *Trafalgar-square*.—ED.]

WELLINGTON STATUE IN THE CITY.

On Saturday, 25th ultimo, the general committee assembled at the Mansion-house for the purpose of completing the final arrangements with the sculptor, Sir Francis Chantrey. The Right Hon. the Lord Mayor in the chair.

Sir P. Laurie presented the report from the sub-committee, which stated that her Majesty's government had presented to the fund for the city statue of the Duke of Wellington, gun-metal taken in his victories by his Grace of the value of 1,520*l*., which, together with the sum of about 9,000*l*. already subscribed, constituted an amount of 10,520*l*. It also stated that the sub-committee had come to an agreement, subject to the approval of the committee, to hand over to Sir Francis Chantrey 3,000*l*. upon signing the agreement, 2,000*l*. with the metal when the small model is finished, and the remaining 4,000*l*. upon the completion of the work. The time for the completion is fixed for the 18th of June (Waterloo-day), 1843. The report concluded with stating that the 6,000*l*. be immediately invested in the government funds, in the names of Sir P. Laurie, Mr. Masterman, Mr. Barclay, and Mr. R. L. Jones, as trustees.

It is to be an equestrian statue of bronze, and not less than ten feet high, from the top of the pedestal on which the horse stands to the top of the head of the rider. The site was not determined upon, but the most eligible one was considerored to be between the Bank and the Globe-office, where the buildings are now occupied by the Sun Fire-office, Messrs. Ladbroke and Co., and Mr. Thomas's, but intended to be taken down to improve the avenues to the new Royal Exchange. Sir F. Chantrey was unable to attend, being engaged at Buckingham-palace with her Majesty, who sat to him for her bust, but his acquiescence in the contract and entire approval of the whole proceedings was signified by Sir Peter Laurie on his behalf.

The committee are to provide a site and to erect a pedestal of granite or some other stone three months before the completion of the statue.

STATUE TO MR. STEPHENSON.

MEASURES are now in progress to commemorate the services rendered by Mr. Robert Stephenson in the improvement of locomotive power. This proposition has originated with the iron trade, and a highly influential committee of iron masters has been formed for its promotion. It is intended to erect a statue, which, on the suggestion of Mr. Hyde Clarke, is to be made of cast iron. We believe that this material has been employed in an equestrian statue at Berlin; no doubt means may be discovered for defending the iron from oxidation. At all events the experiment is worth trying, as its success would enable us to use statues more extensively as a means of decoration. The committee met on the 15th February, when models were laid before them by Mr. Loft and several other eminent artists. We think that there is another name connected with the progress of locomotive power, which is well worthy of some tribute, we mean Richard Trevithick, the inventor of the high pressure system, and the rival of Watt, and to whom the Spanish government proposed to erect a statue of silver.

COLOURED PRINTS.

Instructions to the Printer, or Colourer of Engravings.

The plates to be printed in a bluish-gray ink (this is the neutral tint for the light and shade of the landscape), and the colourer to wash in the sky with blue or violet, &c., according to each sketch; also *going over* the distances with each colour, then wash the foregrounds and middle distances with red, orange or yellow, copying the drawings; and when dry, wash over with blue, to produce the greens in the middle distances: this being done as a dead colouring, a few touches with the hand of the master, and a harmonizing tint to soften the whole, will produce the effect expected from a coloured print.—*Fragment from Repont.*

A Transparent Watch.—A watch has been presented to the Academy of Science at Paris, constructed of very peculiar materials, the parts being principally formed of rock crystal. It was made by M. Rebellier, and is small in size. The internal works are visible; the two-teethed wheels which carry the hands are rock crystal, the other wheels of metal, to prevent accidents from the breaking of the springs. All the screws are fixed in crystal, and all the axles turn on rubies. The escapement is of sapphire, the balance-wheel of rock crystal, and its springs of gold? The regularity of this watch as a time-keeper is attributed by the maker to the feeble expansion of the rock crystal in the balance-wheel, &c. The execution of the whole shows to what a state of perfection the art of cutting precious stones has been carried in modern times.

ANTIQUITIES.

Discovery of Ancient Coins, &c., in the Temple.—Within the last few days the workmen employed in digging the foundation of the chambers in Paper-buildings, Temple, have discovered several earthen vessels of curious construction, some of them containing coins of an ancient date. Many have been purchased, and the spot is daily visited by antiquaries, who evince great anxiety to possess some of the relics.—*Morning Chronicle.*

Egina Casts.—These casts in the British Museum have now been arranged as the originals are in the Glyptothek at Munich, so as to exhibit their position on the pediment of the temple. This is almost the solitary architectural monument in the museum, and it is well calculated to animate the public mind in favour of architectural decorations, while it more than ever induces us to regret the blind policy of the government in having allowed the originals to escape them. The arrangement confers great credit on Mr. Loft, the modeller to the museum, who has had the superintendence of the work.

Venerable Relic.—In the very ancient ecclesiastical structure called King's Chapel, at Islip, in Oxfordshire, formerly stood a stone font, which was used, as tradition affirms, for the baptism of Edward the Confessor, more than 800 years ago. It has long been displaced, and now occupies a far less pious position in the gardens of Sir Henry Brown, who resides not far off, at Nether Roddington, and affords free access to this antiquarian curiosity.

Egyptian Stone Coffin.—There is now on board of the brig Elizabeth Ann, Captain Ellis, lying at the north end of the Queen's Dock, a remarkably ancient Egyptian stone coffin, recently imported from Alexandria, in the vessel called the Hope, whence it has been transhipped, to be taken to the British Museum. It is eight feet six inches in length, measured outside, and three feet six inches in width. It is covered with curious carving of human figures, hieroglyphics, and emblematical devices. It was discovered far in the interior of Egypt, and has been sent to England by our consul at Alexandria. The cost of its conveyance it is supposed will reach 1,000*l*, owing to the want of roads in Egypt, and the necessity of employing men chiefly as carriers.—*Liverpool Paper.*

Sarcophagus.—In the Island of St. Margaret, on the Danube, betwixt Pesth and Ofen, has been found a sarcophagus of coloured marble, and of distinguished workmanship, containing the body of a female, embalmed, and in a remarkable state of preservation. It is clothed in a dress of silver brocade, with a crown of massive gold on the head; a pearl necklace surrounds the neck, and each finger is covered with rings, made of precious stones, besides which there are many other ornaments of the same material, as well as of gold. It is generally thought that it is the body of St. Margaret, daughter of Bela IV., King of Hungary, patroness of the island. The sarcophagus having been taken to the Bishop of Pesth, he has ordered it to be temporarily deposited in the Cathedral.—Near Pesth has also been discovered in a cave, on a hill, amidst the bones of the mammoth, and other extinct species of animals, an ancient vase, of an extraordinary shape, totally new to antiquarians.

At Marsal, in France, workmen excavating the bed of the river Seille have found, amidst the remains of aquatic plants, and buried deep in the soil, twenty skeletons in perfect preservation. They lay in different positions, without any weapons by them some having fractured skulls, some with their face to the ground, appearing to indicate their having been peaceable men, who fell victims to an unexpected attack of warlike invaders. Their necks, their arms, and their legs were surrounded by bronze rings like those found in the tumuli of Brittany. One of these rings, or solid necklaces, is of remarkable workmanship, elegance and finish. This is formed of gold and bronze, and being fitted tight to the neck, so that it could not pass over the head, it must either have been put on the person who wore it in early youth, or have been soldered when on. These relics, supposed to be two thousand years old, are occupying the attention of the antiquaries of France, whose descriptions, details, and suppositions would consume more space than we can spare. The bodies, from the appearance of the ancient brickwork beneath them, appear to have sunk into the soft slime of the river, which has subsequently solidified, and been augmented by successive depositions of earth and aquatic plants.

The Society of Antiquarians of Normandy have decided on elevating once more in its place a miliary stone found in 1819, near Bayeux. It bears an inscription in honour of the Emperor Claudius, and was erected in the XLVI. year of the Christian era. It is the most ancient monument of Romans found in Normandy. In coming to invade England the Emperor Claudius twice traversed France, and Suetonius relates that in the last journey he made, which only took up six months from the moment he left Rome, till that when he returned there in triumph, he travelled on foot from Marseilles to Boulogne. It was probably after these expeditions that he established the military road of which this miliary stone was one of the appendages.

Cathedral of Chartres.—The *Moniteur* publishes a report, addressed to the Minister of Public Instruction by M. Didron, Secretary of the Historical Committee of Arts and Monuments, on the archæological monography of the cathedral of Chartres. Amongst other interesting facts, M. Didron establishes that the statues taken down during the revolution of 1793 from the gallery over the grand portal of Notre Dame de Paris were not the statues of the Kings of France, as has been stated by the Benedictines and Sauval, and as was believed by Napoleon, who intended to repeople the gallery, but simply the statues of the Kings of Juda, the ancestors of the Virgin Mary, and Joseph. In the report the statue of Liberty is also described—a statue belonging to the 13th century, and decorating the northern porch of the Cathedral of Chartres.

A curious and interesting sepulchral monument has lately been discovered at Rome. The ancient aqueducts at the Porta Maggiore, bearing on their lofty entablature the three inscriptions, will be familiar to the recollection of all persons who have visited the antiquities of Rome.—(The reader will find a description of these majestic arches; and the subsequent rude works of Honorius placed against them, in Burgess's "Topography and Antiquities of Rome," vol. ii. p. 311, 312, and 329.) Two of the arches of the Claudian aqueduct served for two gates of the city, respectively conducting to the roads which led to Preneste and Labicum. Stilicho, the general of the Emperor Honorius, placed some cumbrous walls against those arches. In an attempt to clear and repair some of these walls last September, the workmen discovered a portion of a bas-relief, which finally led to the demolition of the tower on the right in going out of the city gate. The towe was found to enclose a remarkable monument, as singular for its construction as for the subjects it represents. It was found in very good preservation. In clearing away the surrounding walls, the next discovery, after the bas-relief, was a slab of marble, on which were two recumbent statues, rather larger than the life, male and female; close by them was the following inscription.—

FVIT ATISTIA VXOR MIHEI
FEMINA OPITVMA VEIXSIT
QVOIVS CORPORIS RELIQVIAE
HOC PANARIO.

The form of the monument is that of a machine which was used by the Romans for enclosing the newly-baked bread, and which was perforated with holes or tubes to let out the steam. These are curiously imitated in the construction of the tomb. The bas-relief represents the whole process of making bread; it runs all round the top, and is supported at the angles by pilasters, the capitals of which are neatly ornamented. These descend half way down, and repose upon a broad square plinth, on which is the following inscription *on one side*:—

EST HOC. MONIMENTVM MARCI
VERGILI EVRYSAC—

On *the other side* the three first words are wanting as far as the M in monimentum and the name of Marcus Vergilius Eurysax is written with some little difference in the paleography. The cognomen of EVRYSACIS, however, is complete, and then follow these three words, PISTORIS. REDEMPTORIS APPARET. On the sides, along the upper part, are placed horizontally, in rows of three, nine hollow stone cylinders, and in the lower part (beneath, the inscription Est Hoc, &c.) two columnar masses are placed perpendicularly, separated by a square block. The "Panarium" was also found, and is carved in the form of a circular wicker basket. It is observable that the southern side of the monument, which probably stood within the property of Vergilius Eurysax, is formed of fine Travertine stone, while the sides exposed to the public roads are of Tufo. The whole of this sepulchral monument was completely enveloped in the comparatively modern wall built against the aqueduct. It is proposed to clear away the obstructing walls, and to lay open the tomb and the Porta Labicana to public view. The two statues have been conveyed to the Vatican Museum. The materials of which this tomb is built, and the paleography of the inscription, appear to show that it is a monument of the republic. It is not improbable that the Travertine stone may have been added at a more recent period: the words QVOIVS, MIHEI, and OPITVMA, may be compared with the inscription on the sarcophagus of L Scipio Barbatus, where we have QVOIVS FORMA VIRTVTEI PARISVMA. RELIQUIAE QVOD is also very ancient.—*Athenæum.*

STEAM NAVIGATION.

Ericsson's Steam-Boat Propeller.—The great power exhibited during the early trials of this propeller, about eighteen months since, induced some American canal proprietors to order an iron steam-boat, with a 50-horse engine, to be fitted with the new propeller. This small iron steamer, called the Robert F. Stockton, has lately arrived in the Thames from Liverpool, and will shortly proceed to the United States; her dimensions are 70 feet length on deck, and 10 feet beam. A variety of experiments have been made in presence of several scientific and practical men, who consider the success to be perfect. Although constructed for towing purposes only, this boat has frequently gone at the rate of twelve miles an hour. As to her power as a tug, we are informed that on Tuesday, Jan. 29, she towed the American packet ship, Toronto, from Blackwall to the lower point of Woolwich, a distance of three miles and a quarter, in forty minutes, against the flood tide, then running from two to two and a half miles; thus towing her through the water at the rate of upwards of six miles an hour. The Toronto is 650 tons burden, she measures 32 feet beam, and drew at the time of the trial 16 feet 9 inches; thus presenting a sectional area of more than 460 square feet. Now the fact of this body having been moved at a rate of upwards of six miles an hour, by a propeller, or piece of mechanism, measuring only six feet four inches in diameter, and occupying less than three feet in length, is one which, scientifically considered, is interesting in the extreme, and in a practical or commercial point of view, is of immense importance. We understand a company is about being formed to apply the propeller to a ship of 1,000 tons burden, to be employed in trans-Atlantic navigation; and as her sailing qualities will not at all interfere with her steaming power, it is confidently anticipated that increased safety will be insured, and her passage greatly accelerated, at a saving of at least one-half the fuel.—*Times.*

Departure of the Great Western, Bristol Jan. 26.—The Great Western having been completely refitted during her stay at Pater, a new quarter deck having been built, and increased stowage-room provided for upwards of fifty tons, sailed this day on her first voyage for New York this season. She set sail at about twenty minutes before six p. m., carrying with her 107 passengers, among whom is Captain Hudson of the Guards, with Government despatches, and Mr. Balls of Covent Garden, upwards of 8,000 letters, and a full cargo of British manufactured goods, consisting of silks, Irish poplins, and cotton goods. She is expected to return about the 7th of March.

Christiana, Jan. 22.—Orders have been given to build an armed steam-boat of 100 or 120 horse power, after the drawings of Lieutenant Sommerfeldt, on the model of the Medea, which is reckoned to be the first armed steam-boat in Europe.

The Kite, Post-office Steam-vessel, running from Liverpool to Dublin, has lately been refitted at Woolwich. Her machinery and boilers are the manufacture of Messrs. Fawcett, Preston, and Co., of Liverpool, who have introduced some improvements into them. On her first trial, about the 22nd of January, in consequence of the immense draft to the boilers, it was considered proper to shorten the chimney eleven feet, which, in ordinary cases, would so check the draft as almost to destroy it. She then proceeded on her second trial, when it was admitted that her machinery was excellent and satisfactory; that the boilers, with the chimney eleven feet shorter, produced a superabundance of steam, the engines making their full complement of revolutions; and, to the surprise of all on board, scarcely any or no smoke was seen issuing from the chimney, which was then explained to be in consequence of the peculiar form of the bridges applied to the furnaces. These are a new invention of Mr. E. Hopkins, 61, St. John-street, Clerkenwell, and have the effect of returning the light fuel and gases on to the fire, when the smoke is consumed, and coals are consequently saved.

FOREIGN RAILWAYS.

Austria.—The rails in the Austrian railways are now made of iron from Styria which are said to be found more durable than those supplied in England.

Austria.—The Austrian government is at present occupied with the plan of a railroad between Vienna and Salzburg, by the way of Lenz, upon the right bank of the Danube, which will be speedily carried into execution. The constant communication upon this road promises every prospect of success to this undertaking.

The Versailles and St. Cloud Railway.—The works have been commenced at five points at once within the commune of Versailles, and are carried on with the utmost activity. As the works on the other parts of the line are nearly finished, the whole of the two lines of rails are expected to be laid from Asnières to the limits of Versailles before the end of the month. Independent of the ordinary works, the company has had to form the tunnel under the Park of St. Cloud, 1654 feet in length; another tunnel of 607 feet, under the Park of Montretout, and the high road between Saint Cloud and Mantes; a third tunnel of 272 feet, at Courbevoie, under the road between Paris and Poissy; two large viaducts of five arches each; 36 bridges over high, departmental, and cross-roads, and 10 aqueducts. There remain besides five bridges to be erected in Versailles. All these works are comprised within a limit of four and a half leagues. In the plan laid down by the government engineers, upon which the undertaking was founded, there were only one tunnel, 28 bridges, and four aqueducts mentioned; and the greater part of the additional works have been occasioned by the decrees of the municipal councils.

St. Cloud Railway.—The jury of expropriation has just decided at Versailles upon the indemnities to be paid to proprietors affected by the last portion of the line of the Versailles and St. Cloud Railroad, from Viroflay to its entrance into the first-named town, but the sums awarded have in general been much less than those demanded. Property in Montreuil, for which 656,755f. were demanded, has been adjudged at 264,111f. Ten houses in the same place, estimated by the owners at 207,343f., have been awarded at 83,400f. Some gardens in Versailles, for which 211,615f. were asked, have been given to the company by the jury at 50,200f.; and the total amount of 1,548,150f. for the portion of the line has been reduced to 640,665. Two extreme cases deserve to be mentioned: the lessee of a field at Versailles demanded 21,243f. as an indemnification for one acre of land, and produced documents signed by some architects of that place in support of his estimate. It was, however, reduced by the jury to 400f. Another proprietor claimed 6,620f. for the suppression of a right of way across his land; the company offered 10f. for it, and the jury awarded him nothing.

Belgium.—From a report recently laid before the Belgian Chamber of Representatives by the Minister of Public Works, it appears that the total expense of maintenance, purchase, and repair of machinery, watching, &c., of the Belgian railways since the completion of the first line in 1834, up to the 1st of November, 1838, is 3,374,570frs.; that the total receipts during the same period have been 5,144,645frs.; giving a net profit of 1,770,075frs., which, upon the capital expended in the construction of the roads, returns an annual dividend of 4 per cent. The average cost of the construction per league has been 531,000frs., about a sixth of the cost of the English lines; and the average price paid by passengers is 12 centimes per league, about a fifth of the lowest rate of charge in England. The total length of the Belgian lines, now completed, is 64 leagues, about 270 miles.

Russia.—The Hamburg papers mention, upon the faith of letters from St. Petersburg of the 12th December, that a new railroad was about to be established from the town of Morschausk, on the river Zora, to the mouth of that river, in order to facilitate the communications of some of the richest provinces of the south, which send all their wares and produce to Morschansk, one of the first commercial towns of the empire, with St. Petersburg and the north.

Proposed Railways in America.—One of the grandest railroad schemes ever conceived by the mind of man, has been submitted to the public by General Gains, of the United States army. It proposes a system of railroads, all diverging from a common focus or centre in Kentucky and Tennessee—the middle point of the Union; and thence to branch in as straight directions as possible, like the radiations of a star, to all the large cities, and important frontier posts in the country. Thus New Orleans, Portland in Maine, New York, the other Atlantic cities, and Detroit in Michigan Chicago, in Illinois, Fort Gibson, in Arkansas, St Louis, in Missouri, the northern lakes, and the southern sea of Mexico, the ocean and perhaps the Rocky Mountains, will all be united in bonds of iron, steam, and rapid public intercourse. The General says that such a system would make the United States prosperous in peace and impregnable in war. I think that before many years have rolled away this scheme will be commenced. The United States are the very republic for railroad enterprise.—*Daily Paper.*

The New Philadelphia railroad is at present doing an excellent business; the month of December, one of the dullest of the year, will realise over 8,000 dollars. January and February are the months when the merchants from the western states commence their purchases for their spring business, when the amount of freight passing over our road will be very great. I feel more and more satisfied of its being one of the very best stocks in our state, and you can with perfect safety give the bondholders every assurance that their bonds will increase in value every year they hold them. The Cumberland Valley have completed their bridge over the Susquehannah, and formed their connexion with our road, which will enable our Philadelphia merchants to forward their goods 160 miles by railroad in thirteen hours towards Pittsburg, which is just half way. Formerly goods were 18 to 20 days reaching Pittsburg, and you, who are so familiar with the rapid increase of the population of the western states, and their consequent necessities, dependent entirely on our Atlantic cities for their supplies—you can readily calculate the great importance of our road, and the certainty of its immense revenue."—*Morning Herald.*

FOREIGN INTELLIGENCE.

The completion of the *Column*, in commemoration of the Revolution of July, may at length be expected within a definite time. Messrs. Soyer and Inge a few days' since cast the capital and the tambour, by which it is to be crowned, in one mould. This is the largest single cast of a capital that has ever been made.—*Paris Paper.*

Two new marble statues, those of Lakain and Talma, have just been stationed right and left of the author of *Zaire* in the hall of the Theatre Français.

Iron Steam Ship.—There was launched from the building yard of Mr. C. Wood, Dumbarton, on the 22d Jan., an iron steam-ship, 146 feet long, and 25 broad, intended for South America. On being launched this vessel drew only eighteen inches water, and with machinery and cargo will not exceed three feet. She is intended for passengers chiefly, of whom she can carry a thousand. This fine vessel was built by Messrs. J. and W. Napier, in Glasgow, and we understand that these gentlemen have her machinery ready for putting on board, so that we shall soon have an opportunity of seeing this splendid specimen of the improvements of the present day leaving our river for a distant part of the world, another trophy of the success of the enterprising engineers on the Clyde. She is now at the Broomielaw, and is worthy of inspection. The carpenterwork of the vessel was done by that eminent shipbuilder, Mr. C. Wood, of Dumbarton.—*Glasgow Paper.*

Steam Navigation to South America.—A memorial, which includes among its signatures those of Baring, Gladstone, Rothschild, and other firms of mercantile, banking, and manufacturing eminence, has just been presented to the Treasury, praying for a monthly line of steam-packets, from Falmouth to Madeira, the Canaries, the Cape de Verd Islands, Pernambuco, Bahia, Rio de Janeiro, Monte Video, and Buenos Ayres. The packet establishment now existing is so irregular, that with the ports of Pernambuco and Bahia a communication can be had but six times in the year, trade winds and ocean-currents hindering any sailing vessel from touching at either, except during some half-dozen months of a periodical season. The passage outwards to Rio de Janeiro averages fifty-six days, and homewards seventy-four, while, from computing the speed of the Great Western steamer across far less favourable seas, two-thirds of that time might, in all probability, be saved. An allowance of 40,000*l.* per annum is at present made for the tardy packets upon this important line, and for the same sum contractors could doubtless be found to deliver twelve monthly mails outwards and homewards, in steam ships of the very first class. We do not surely err in anticipating for this memorial the most immediate and attentive consideration which Government can give it.—*Daily Paper.*

The *Debats* quotes letters from Havannah, announcing that the magnificent Government steamer Véloce, Capt. Béchameille, which had recently entered Havannah after its transatlantic experimental voyage, had been burned in that habour.

PROGRESS OF RAILWAYS.

Eastern Counties Railway.—The rapid progress of the works on this line bespeaks an active executive. We had no idea of the forward state of the works towards Brentwood. It was only in October last that the contract was let, and looking to the time of year we considered nothing would have been done but prepare for the spring. On inspecting this part of the line, we found the works in full operation; several bridges and large culverts erected, and the embankments carried over them. There are three extensive cuttings on this contract, all of which are in full work, even during the late and present unfavourable weather there has been excavated and carried to the embankment near 200 yards per day. The cutting in the hill on this side of Brentwood is so deep as to be carried on in four lifts, near to this excavation is erected a handsome skew bridge, the angle of which is very oblique, we should suppose about 40deg. At Romford great activity prevails, several large bridges and culverts are in the course of erection; close by at Hare-street, a large bridge over the railway, of three or more arches, is commenced, the foundations are about 35 feet below the surface. Between London and Romford there are five locomotive engines incessantly employed in expediting the earthwork, besides an immense number of horses. The long and expensive embankment over the Stratford Marsh is now just completed; and as the distance between its termination and the commencement of the viaduct at Bethnal Green has been formed from side cutting, there remains nothing of importance between London and Romford but the viaduct, portions of which are in a very forward state.

Bristol and Exeter Railway.—Within the last few months coffer dams have been driven preparatory to the erection of a bridge, 100 feet span, over the river Paret, about three-fourths of a mile higher up that river than the town of Bridgewater. The contractor is now employed in building the abutments, and the arch will be turned in the latter end of the spring, when the work towards Taunton will be begun immediately. The cutting at Pariton Hill is proceeding with much vigour, upwards of 500 men are employed on it at present, and more will be shortly. This is the only hill, for many miles, and as soon as it is got through, which, if the Company go on at the rate they have begun, will be soon, nothing remains but to lay the permanent rails. The broad guage will of course be adopted. The town of Bridgewater possesses facilities for being made one of the principal manufacturing towns, and one of the first ports in the kingdom; and when the communication with London on the one side, and the West of England on the other, is opened, we know nought more wanted, save a few more spirited men in the middle.—*Bristol Journal.*

Birmingham and Gloucester Railway.—Mr. Norris, of Philadelphia, has received an order for ten of his locomotive engines, from the Birmingham and Gloucester Rail road Company, in England.—*New York Paper.* If this be correct we are not surprised that the shares of this company are at a great discount. Do they expect English men will support their projects if the money subscribed is to go out of the country? and does the company expect that the public will have any confidence in the safety of the engines when made abroad.—*Ed. C. E. and A. Journal.*

London and Brighton Railway.—The locomotive engine which has been named "The *Brighton*," lately sent down by the railway company to facilitate the works on the Shoreham branch, was tried on a portion of the line, about a mile and a half in extent, on which the permanent rails have already been laid. We are happy to state that the works on the Shoreham branch are progressing with great activity. The tunnel under Lashmar's mill is proceeding night and day; and the land purchased of Mr. Kemp has been enclosed from the mill to the terminus, crossing the Montpellier road. As great a number of excavators as the space will admit are engaged on the cutting at Fuller's-hill, in the parish of Aldrington; and as soon as this is completed, which it is anticipated will be the case in a month, permanent rails will be laid for the distance of about four miles, and the engine will be used for the purpose of removing the earth from the cuttings and tunnels at the Brighton end of the branch. The works on the London part of the line are also proceeding with great rapidity.—*Brighton Gazette.*

Havre.—The Minister of Commerce, it is reported at Havre, has informed the Chamber of Commerce of that place, that Government intends proposing to the Chambers a grant of 150,000f., for the formation of two trenches in the new entrance port, in order to enable large steamers to lie there afloat at low water. To this plan the *Journal du Havre* is opposed, as being a poor substitute for a large dock, especially devoted to the reception of steam-vessels, which the town of Havre has been anxious to have constructed, in order to be enabled to set up a line of steamers to New York.

Havre.—A few days since a considerable portion of the cliff at Cape La Hève, near Havre, gave way, and carried with it into the sea upwards of 140 feet by 12 feet wide of land which was in cultivation.

A chain-bridge over the Allier at Vic-le-Comte gave way for the second time a few days since. The first time it sank under the weight put upon it to try its strength, but was rebuilt with greater solidity. The second broke down while a wagon heavily laden was going over. The vehicle with its contents fell into the river, and was lost with the horses; but the driver was fortunately saved.

La Tour d'Auvergne.—A monument is about to be erected to Corret de la Tour d'Auvergne, known in the French army as the "First Grenadier of France." The monument to this gallant Breton is to be erected at Carhaix, his native town, which has voted 200*l.*, the Council-General of the department having added 40*l.*

The French King has approved of a proposition laid before him by the minister of the marine, for commencing in the spring a hydrographical survey of the French coast in the Mediterranean. The result of this survey, when published, will form a supplement to the *Pilote Français*. The operations are to be under the direction of M. Mounier, hydrographic engineer of the first class.

The steam-generator of M. Girand's sugar-manufactory, at St. Saulve-lez-Valenciennes, burst during this month; and, although it weighed 6,000lbs, was forced upwards through the ceiling and roof, and carried to a distance of 100 feet, together with the tubes, and other apparatus attached to it. Two of the stokers, who were at the fires, were seriously injured.

The minister of the interior has granted 2,000f. to be applied in the restoration of a fine specimen of the statuary of the middle ages, called the *Puits de Moise*, in the ancient monastery of the Chartreux, at Dijon.

French Coasting Trade in 1837.—The number of vessels employed in that trade in 1837 was 64,900, carrying 2,209,269 tons, and manned by 264,152, and the whole of their cargoes weighed 900,000 tons, or 17,821,691 metrical quintals. The trade of the different ports, in metrical quintals, is as follows:—Rouen, 2,005,509; Marseilles, 1,734,820; Bordeaux, 1,446,610; Havre, 1,254,777; Nantes, 623,571; Toulon, 516,084; Dunkirk, 400,442; La Rochelle, 344,486; Caen, 338,290; Libourne, 301,200; Cette, 217,550; Arles, 215,728. The trade of the Mediterranean ports is only one-fifth of the whole, and the whole coasting trade is twice as much as the French foreign trade, and three-quarters of the whole foreign trade.

A fine marble statue of the illustrious Goethe, executed at Milan, by Marchisi, at the expense of three citizens of Frankfort, has arrived in that city, which was the great poet's native place. The statue is to ornament the principal room of the public library.

The *Milan Gazette* gives the following details of the organization of the institutes of sciences, arts, and letters, and the technical schools recently founded at Milan and Venice by the Emperor of Austria:—"The institute at Milan will be composed of three classes of members—ordinary, honorary, and corresponding. The first will be 40 in number, twenty of whom will receive a stipend of 1,200f. per annum each. The object of this institute is to encourage studies which may influence the prosperity of the Lombardo-Venetian provinces by the cultivation of science. All that attend to the improvement of agriculture, the useful arts, and commerce, as well as of letters, will be under its care. It will have to award prizes at Milan and Venice to such Lombardo Venetian subjects as have invented or introduced any new branch of industry, or fresh source of prosperity. The journal *La Biblioteca Italiana* is to be made the *Journal of the Institute*, in which reports of its proceedings are to be regularly inserted. The Academy of the Fine Arts, founded by the Empress Maria Theresa, is henceforth to be subjected to fixed regulations. The professors are to have specific ranks and classes, and to be associated with counsellors, ordinary and extraordinary, honorary members, and artists. It will be endowed with an ample revenue for the distribution of annual prizes. The technical schools are to be established at Milan as well as at Venice. Such youths as are intended for commerce will be taught in the writing, arithmetic up to its highest degrees, the Italian, French, and German languages, history, geography, book-keeping, and the whole system of commerce. Those who are destined for the useful arts and manufactures, will be instructed in physics, natural history, and chemistry, as applicable to the arts. For such as devote themselves to the fine arts, drawing schools are to be established."

The Saxon government are about to construct a theatre at Dresden, upon a scale of magnificence hitherto unequalled, and MM. Semper and de Lüttichaw, of Dresden, have been sent to London, Paris, and Italy, to ascertain what improvements have been made in this department. Mr. Stephenson's machinery is expected to be adopted in this theatre also, Professor Semper having proceeded to Paris to meet Mr. Stephenson, who was in attendance upon the French commission.

Swedish Navy.—Orders have been given to build an armed steam-boat of 100 or 120 horse power, after the drawings of Lieutenant Sommerfeldt, on the model of the *Medea*, which is acknowledged to be the first armed steam-boat in Europe.

The Russian journals announce that Professor Jacobi, of St. Petersburg, has succeeded in transferring engravings on copper to other plates, formed of a certain composition, by means of a galvanic process, reproducing, with exactitude, the most minute lines. The emperor, it is added, has granted sufficient funds for perfecting this discovery.

Turkish Opera.—The theatre at Pera is building by two French architects, and is to be finished towards the end of next summer. In the mean time, a house has been rented near the place of Atmeidan, where Italian operas are performed three or four times a-week. There is accommodation in this temporary theatre for about 1,600 spectators, and it is said to be always full, notwithstanding the dearness of the prices, which vary from 10f. to 50f. The Sultan has already honoured this place of amusement with his presence. The performers, for the most part, belong to an Italian company who have acted at Odessa. The Prima Donna, a Milanese lady, appears to be making a good thing of it at Constantinople; for, being well skilled in the Turkish language, she is engaged to give instructions in singing in the first Mussulman families of the Turkish capital, and is stated to be carried about to her pupils' residences in a splendid litter, covered with gilding and crimson velvet curtains, and carried by four black slaves, who are preceded or followed by eight others.—*French paper.*

Constantinople Medical School.—On the 10th December, the Sultan visited the new building just terminated at Galata Serai, in Pera, for the Medical School. The establishment is intended to be very complete, as there is a dissecting room, library, museum, botanical, chemical departments, hospital, and everything necessary for the education of young doctors there. The students are to take up their quarters there shortly after the bairam.

A line of telegraphs is being established at Constantinople; and a successful trial has already been made on the Bosphorus. It is intended to extend to the Dardanelles, and subsequently two more branches will convey intelligence to and from the extremes of the European provinces, whilst others are to lead far into Asia Minor. The best part of them at present is, that they are not expensive.

A letter from Bucharest states, that the project of cutting a canal from the Danube to the Black Sea is to be carried into execution during the spring, by the common consent of England, Austria, and Turkey; and that the last of these powers has issued an order for a levy of 20,000 workmen for this purpose.

Upper Syria.—M. Eusebe de Salle has just returned to Beyrout, from a tour through Upper Syria, as far as the Tamian Chain and the Desert of Palmyra. This country is a species of Syria Petrea. The plains of Antioch of the Turkomans, and the valley of the Orontes, present at every step ruins, sometimes of entire towns, which date either from the most remote antiquity or from the Byzantine period. In the Upper Orontes alone, Prince Puckler Muskau professes to have discovered upwards of ten cities or towns omitted on the most accurate maps. M. de Salle has discovered at least as many between Antioch and Aleppo. The constructions with which he was most struck are Roman camps or redoubts, built probably between the times of Crassus and Trajan, during the wars of the Parthians. These antique piles, which are still remarkable for their solidity, were retouched by the Byzantines, the Turks, the Saracens, and the crusaders, which has no doubt hitherto prevented them from being recognized.

Road to the Red Sea.—We learn by letters from Alexandria, that 800 Europeans crossed the isthmus of Suez last year, on their passage to and from India; and that a regular coach conveyance will be soon established between the shores of the Levant and the nearest points for embarkation on the borders of the Red Sea.—*Bath Guardian.*

ENGINEERING WORKS.

Pure Water.—Four of the Water Companies of the metropolis, viz., the New River, the East Middlesex, West Middlesex, and the Grand Junction intend to apply to Parliament for power to draw their water higher up the Thames, so as to improve its quality.—*Morning Advertiser.*

The Portland ferry bridge has been opened with a grand procession, both of civil and military.

River Lune Navigation.—We find by the *Lancaster Guardian* that a discussion on this important subject is occupying the people there. Mr. Rooke, the author of "Geology as a Science, applied to Engineering," in objecting to the plans adopted by the Messrs. Stevenson, adopts their own data, that the force of the flux of spring-tides in the River Lune exceeds that of the reflux more than two-fold; and then goes on to prove that it is the backwater which is the cause of the setting up, and that instead of shutting out the tidal action, as recommended by Messrs. Stevenson, that it is necessary to allow it greater play. Engineering subjects like this and the Morecambe-Bay subject form the staple material of the local papers in the north-west counties; and while the profession must benefit by this excitement of public interest, so the cause of science is promoted by directing the attention of engineers to the laws of natural action. It is perhaps the misfortune of engineers that whereas in other cases they have only to deal with inert masses, in the construction of harbours they are drawn from their old habits to a new competition with the active forces of nature.

New Docks at Liverpool.—A capacious dock, to be called the Egerton Dock, is being now constructed at the south end of the town, adjoining the Herculaneum Pottery, for the use of the immense and still increasing carrying trade of Lord F. Egerton. The dock trustees also contemplate the enclosure of the strand to the westward of Trentham-street, and the formation of two docks, running east and west, in lieu of the present Salthouse Dock. This central position, adjacent to the New Custom-house, and within a few minutes' walk of the Exchange, will be of immense advantage to the commerce of the port. It appears also, that by removing the present graving docks to the extremities of the town, a further addition of 10 or 12 acres may be obtained to meet the increasing wants of the port, together with a large entrance-basin, in lieu of the present inconvenient old dock gut. The land to the westward of the Salthouse Dock now produces a very trivial rent, being principally occupied by ship-building yards; and by carrying out these bold designs, dock space will be provided for many years to come in the very centre of the town, and the necessity of any further extension will be obviated to the northward, more especially where the difficulty of docking vessels in bad weather is severely felt.—*Liverpool Times.*

Bow Bridge.—On Thursday, the 14th ult., the new bridge erected over the river Lea, at Bow, was opened with ceremony by Mr. Alderman Thomas Wood, the sheriff for Middlesex, and Mr. W. Colten, the sheriff of Essex, attended by a numerous train of the magistrates and gentry of the two counties.

MISCELLANEA.

St. Saviour Southwark.—The demolition of the nave of this ancient collegiate church is about to commence; the old materials have been sold, and directly they are removed, the building of a new church on the site, at an expense of 8,000*l.*, to be connected with the present tower and the choir, in which divine service is now performed, will be proceeded with.

Geology.—A few days ago a tremendous fall of chalk took place at the facing of the rock forming the entrance of the west tunnel through Shakspeare's Cliff. By this fall the geologists have a treat, as the vertebræ of an immense animal has been laid bare, and it is expected that the remaining parts of the skeleton will be found on the removal of the fallen rubbish.

A Sheet of Paper.—There was lately sent from the paper manufactory at Colinton a single sheet of paper weighing 553lb., and upwards of a mile and a half in length; the breadth was only 50 inches. Were a ream of paper composed of similar sheets made, it would weigh 266,500lb., or upwards of 123 tons.—*Scotsman.*

We recommend to the notice of the profession, Mr. Day's, Advertisement, his pencils we have tried, and find the lead to be of a good quality, and may be depended upon as being of one degree of hardness through the whole length of the lead.

Mr. P. Thomson, on Thursday, the 21st ult., obtained leave to bring in a bill to provide for the copyright of designs for articles of manufacture, and a bill for extending the copyright of designs for calico printing to other woven fabrics.

Lace Caps.—A new and important manufacture has lately arisen in the hosiery trade, in making lace caps from the stocking-frame, by the aid of the jack tickler machine. This machine has been latterly applied to the making of laces in breadths, and with such brilliant success as to astonish even the oldest workmen.—*Nottingham Journal.*

Iron Statues.—A correspondent, M. G., suggests that as it is of importance that public statues should be executed of a cheap metal, whether the use of iron might not be contemplated to be preserved from rust by the preparation of the Anti Oxidisation of Metals Company.

Carvings in Wood.—Two very curious and very elaborate carvings, in walnut-tree wood, of the alto-relief class, have just been brought to this country. They were formerly in the possession of the Emperor Napoleon, whose eagerness to possess the rarest gems of art was much more than commensurate with his respect for *meum* and *tuum*. These carvings are each about five or six feet in length, and about three or four in height or width. One of them represents the victory of Constantine over Maxentius. The design is from Julio Romano, and is known to artists. It contains upwards of two hundred figures of combatants, horse and foot, mingled and grouped with great pictorial effect, and carved with extraordinary boldness and accuracy. The finish of the armour, costume, and minute details is very delicate. The second tablet is after a design by Rubens; some of the figures are after Leonardo da Vinci. The subject is the scriptural battle in which Joshua commanded the sun to stand still. This carving is in higher relief than its companion; it contains fewer figures, and most of them are equestrian. It is full of spirit, and cut with great freedom of hand. These carvings, which certainly surpass anything that is generally to be seen in this country, are by an Italian artist, Simon Cognoselli, and bear date 1761. Upon the downfall of Napoleon they were returned to their original locality, the Castle of Salms.—*Gent's. Mag.*

A GREAT HURRICANE.—A severe hurricane has devastated the north-west of Europe. It is supposed to have come from the West Indies across the Atlantic, and spent its chief fury in the Irish sea. Liverpool, Manchester, and Dublin, particularly suffered, and the loss of shipping is very great, besides the damages to public works, parks, and trees. The loss of life in Ireland is said to have been above 200 persons. The hurricane swelled up the waters in the north sea to such an extent, that irregular tides were produced, the coast works of Denmark, Germany, and Holland, severely injured, and the waves of the Elbe forced up into Hamburgh four feet above the level of the Exchange. A remarkable feature is the deposition of sea salt eighty miles inland in Ireland, Lancashire, Cheshire, and Yorkshire.—*Wyld's Monthly Index and Register to the Metropolitan Morning Papers.*

GEOLOGICAL HISTORY OF LAST MONTH.—The principal geological events are presented by the effects of the activity now prevailing in the volcanic basin of the Mediterranean. The eruption of Mount Etna has ceased, but that of Vesuvius continues, and in the early part of the month supplied a great quantity of cinders and lava. Earthquakes have been felt at Edinburgh, Leicester, Berlin, and Malta. Coal has been discovered in Greece.—*Wyld's Monthly Index.*

NEW PATENTS.

LIST OF ENGLISH PATENTS GRANTED BETWEEN THE 29TH JANUARY, AND THE 23RD FEBRUARY, 1839.

THOMAS COLLETTE, of Aylesbury, in the county of Buckingham, for "Improvements in Children's Cots."—21st January; 2 months to specify.

CHARLES JAMES BLASIUS WILLIAMS, of Half-Moon-street, Piccadilly, Esq., M.D., for "Certain Improvements in two-wheel Carriages."—29th January; 6 months.

ROBERT CAREY, of Breadgar, Kent, gentleman, for "Certain Improvements in Paving, or Covering Streets, Roads, or other Ways."—29th January; 6 months.

FRANK HILLS, of Deptford, Manufacturing Chemist, for "Certain Improvements in the construction of Steam Boilers, and of Locomotive Engines."—29th January; 6 months.

THOMAS BARNABAS DAFT, of Regent-street, gentleman, for "Certain Improvements in Ink-stands, and in Materials and Apparatus for Fastening and Sealing Letters, or other Documents."—2nd February; 6 months.

MOSES POOLE, of Lincoln's Inn, Gentleman, for "Improvements in the means of conveying and transporting Persons and Goods from one place to another."—4th February; 6 months.

JOHN EVANS, of Birmingham, Paper Manufacturer, for "Improvements in the Manufacture of Paper."—4th February; 6 months.

THOMAS ROBINSON, of Wilmington-square, Middlesex, Gentleman, for "Improvements in the process of Rectifying or Preparing Spirituous Liquors in the making of Brandy."—7th February; 6 months.

CHRISTOPHER BINKS, of Newington, Edinburgh, Manufacturing Chemist, for "Certain Improvements in Obtaining or Manufacturing, and in rendering Chlorine, the useful Chlorides of Lime and Soda, and other Compounds of Chlorine applicable in Bleaching."—8th February; 6 months.

CHARLES GABRIEL BARON DE SUARCE, of Red Lion-square, Middlesex, Colonel in the French service, and WILLIAM PONTIFEX, of Shoe-lane, in the city of London, Coppersmith, for "A new mode of obtaining Dyes, Colours, Tannin, and Acids, from vegetable substances."—11th February; 6 months.

GEORGE HENRY MANTON, of Dover-street, Piccadilly, Gun Maker, for "Certain Improvements in Fowling Pieces, and other Fire Arms."—11th February; 6 months.

EDWARD PEARSON TEE, of Barnsley, York, Dyer, for "Improvements in Weaving Linen, and other Fabrics."—11th February; six months.

JOHN THOMAS BETTS, of Smithfield Bars, Rectifier, for "Improvements in the process of preparing Spirituous Liquors in the making of Brandy."—11th February; 6 months.

FREDERICK CATLEY WORSLEY, of Hollywell-street, Westminster, Esq., for "Certain Improvements in Locomotive Engines and Carriages."—14th February; 6 months.

RICHARD PROSSER, of Birmingham, Civil Engineer, for "Certain Improvements in Apparatus for Generating Steam, Consuming Smoke, and Heating Apartments."—19th February; 6 months.

MOSES POOLE, of Lincoln's Inn, Gentleman, for "Improvements in Epaulettes and Ornamental Metallic Wire Fringe, and other Ornamental Articles or Fabrics of Wire. A Communication from a Foreigner."—21st February; 6 months.

JOHANN ANDREAS STUMPF, of Great Portland-street, Musical Instrument Maker, for "Improvements in Grand and other Pianofortes."—21st February; 6 months.

MATTHEW UZIELLE, of Fenchurch-street, Merchant, for "Improvements in Locks or Fastenings."—21st February; 6 months.

HERBERT REID WILLIAMS, of Gloucester, Surgeon, for "Improvements in Trusses and Surgical Bandages."—21st February; 6 months.

THOMAS HALL, of Leeds, Brass Founder, for "A New Combination or Arrangement of Parts, forming an Improved Furnace for Consuming Smoke, and Economising Fuel, applicable to Steam-engine Boilers and other Furnaces."—21st February, 6 months.

WILLIAM NASH, of Budge-row, Merchant, for "Certain Improvements in the Constructions of Bridges, Viaducts, Roofs, and other Parts of Buildings."—23rd February, 6 months.

JOHN SYLVESTER, of West Bromwich, Stafford, Whitesmith, for "Certain Improvements in the Arrangement and Construction of Apparatus for Hanging and Closing Doors."—21st February; 6 months.

WILLIAM JOHNSON, of Saint Mary Cray Paper Mills, Kent, Paper-maker, for "A Certain Improvement, or Certain Improvements, in the Manufacture of Paper."—21st February; 6 months.

WILLIAM NASH, of Budge-row, Merchant, for "Improvements in Machinery for Winding, Spinning, Doubling, and Throwing Silk and other Fibrous Materials."—23rd February; 6 months.

OBITUARY.

Death of Rudolph Cabanel, Esq., Architect.—On the 4th of February Mr. Cabanel, after a long and severe illness died at his house, Mount Gardens, at the age of 76. He was a native of Aix-la-Chapelle, but had lived in England since his boyhood. He was the architect of the stage of Old Drury-lane, for he blended with high talents as an architect an ingenious and inventive turn of mind, and an extensive scientific and mechanical knowledge. He was the sole architect of the Coburg Theatre, which, as he left it finished, was acknowledged by the most competent judges at the time to be the most perfectly-constructed theatre in London, or perhaps in England. He was the sole inventor of the roof known by his name, besides a number of machines and other matters of great value. He lived much respected and died much regretted by a numerous and highly respectable circle of friends.—*Morning Advertiser.*

ERRATA.

In our last number, page 35, 1st column, line 2 of 4th paragraph, "polished and *gilt.*" Now the bronze capitals and bases of the columns of the Isaac Church, at St. Petersburg, are *not* gilt, neither have they ever been, or will they be.

Page 37, 1st column, Candidus, describing the Isaac Church at St. Petersburg, says, "The height of the dome is 340 Russian feet, or nearly 400 English ones." We are not prepared to say whether the height be 340 or 400 feet; but Candidus is under a great mistake regarding the value of the Russian foot, which is *identical* with the English foot. We are the more anxious to see this error corrected, as it is as generally as erroneously imagined that the Russian and English foot are different measures, whereas they are *exactly one and the same.*

Page 43, 2nd column, lines 39 and 40, for "level, when," read "level with."

Page 44, 1st column, line 1, for "indicates our," read "indicates the correctness of our."

ADDRESS.

Our readers will perceive, by the cover, that we have this month added another sixpence to the price of the Journal, and they will see, by its contents, that the enlargement of size, and increase of wood engravings, have been proportionate to the additional charge. This measure has been reluctantly forced upon us by the extent of matter which we have hitherto been obliged to reject, and we trust that every one will feel that this has been done less for our own profit than the public advantage. This increase of size we have long resisted, but its necessity has now become so apparent, that, however unwillingly, we have been compelled to submit to its adoption. As we feel convinced, however, that cheapness is most conducive to our own interest and the public convenience, we shall, if the press of matter should diminish after the present season, again reduce the size to its old standard.

For this increase of matter we are principally indebted to the engineers; and though we have every disposition to give equal scope to architecture, we regret that the extent of communications we receive from that branch of our readers, is not correspondent to our desire to do justice to their wishes. We earnestly request from all classes the communication of anything they may deem likely to promote the objects of our Journal; and we are sure they will feel convinced that no want of attention on our part will ever cause them to regret their exertions in its favour. We may, in conclusion, confidently appeal to our past efforts, and the present number, to show that, while we do everything in our power to merit the support of our readers, we have not been inefficient in fulfilling this desire.

TO CORRESPONDENTS.

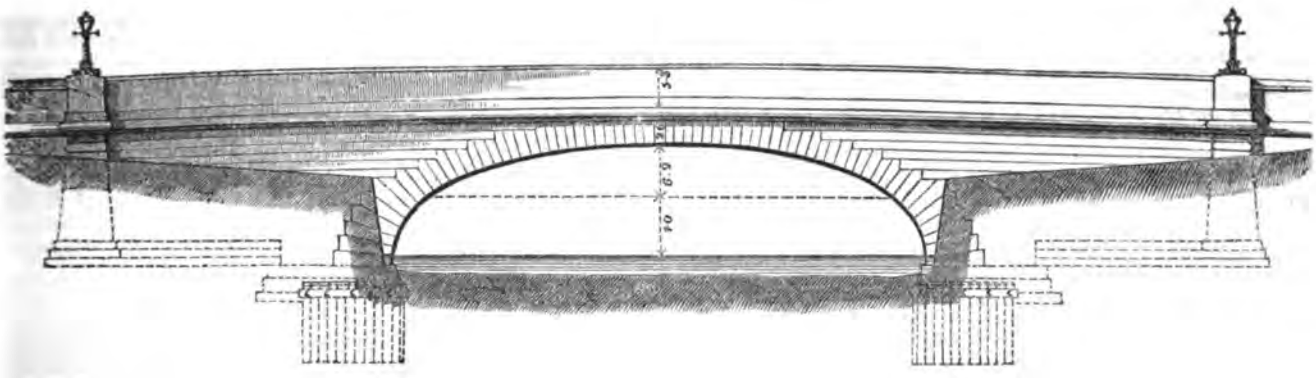
We have just received, as we were going to press, a satirico-poetical effusion from one who signs himself "A Candidate vanquished, but not castdown," of which we can now spare room for no more than the concluding couplet, which is not without some point.

"Hurrah! for brave Nelson, now England may boast,
That in death, as in life, he still sticks to his *post.*"

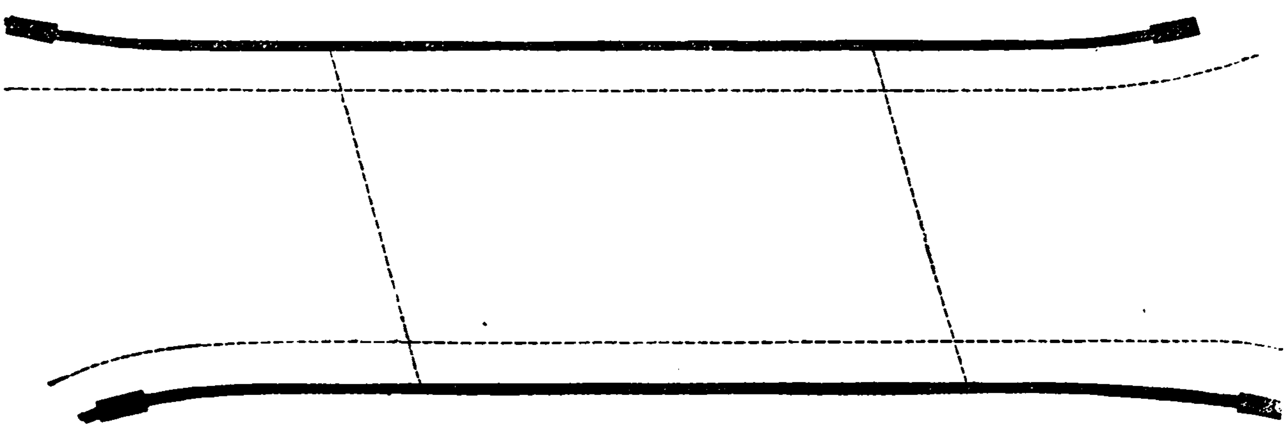
BOW BRIDGE.

ENGINEERS, MESSRS. WALKER AND BURGES.

Elevation of the New Bridge.



Plan of Roadway.



Section of Roadway and Centre of Arch.

Scale of Feet.

View of the Old Bridge.

BOW BRIDGE, AT STRATFORD-LE-BOW, IN ESSEX.

The great and still-increasing traffic between the county of Essex and the metropolis has of late years led to many important improvements in the line of the Great Essex-road, but nothing yet done has been so highly appreciated by the public as the new bridge across the river Lea, at Bow, which is built upon the site of the ancient structure and was opened for traffic last February. Before we proceed to describe the new bridge, we will give some particulars of the old bridge, a view of which is given above, a description of it we extract from an interesting account by Mr. Burges, in the Archæologia, vol. 27, pp. 77 to 95, communicated May 17, 1836.

Of the antiquity of Bow Bridge there can be little doubt, as we have proved from the best authorities that it was erected by order of Matilda, queen of Henry the First, which must have been between the years 1100, when she became queen, and 1118, the year of her death.

If any portion of the present structure can be identified as part of the original edifice, it may be considered, if not the oldest bridge extant, as at all events possessing an age which few other bridges in the kingdom can so satisfactorily trace, the long period of upwards of seven hundred years, and it must consequently be considered as a highly interesting work of antiquity.

In the construction of this bridge, we find all that characterises the very early specimens of bridge architecture; the small openings for the water, and wide piers with large angular projections, not only to divide and throw off the force of the current, but for foot passengers to retire into, to avoid the danger from carriages and horsemen when passing along the narrow roadway.

"That the bridge was originally built of stone can need no further confirmation; but the number of arches it originally consisted of is a question we have now no means of ascertaining, though, in all probability, it never had fewer openings than it has had in our day. Lysons indeed states it be a bridge of one arch, but he does not give his authority; neither have I met with any other writer who has favoured that opinion, or advanced one argument to lead to such a conclusion. That it had at any time more than the present number of arches is uncertain, unless it were furnished with small openings or archways at each end under the causeway for the passage of the land floods; but if there were such, they could not in fairness be considered as forming any part of the bridge. Of such arches, however, I have not been able to discover the slightest remains, either from the excavations made purposely to determine that point, or from any examinations of the bridge itself.

"That the present pointed arches formed no part of the original construction of the bridge must be evident, as no other but a circular arch would have been used at that time; the pointed form of arch not having been introduced into the buildings of this country till many years after. The original arches therefore appear to have been removed, and may probably have given place to several forms of construction, each partaking of the fashion prevalent at the time of their erection. It may also be observed that the form of the present arches is of that particular description which was last of all introduced into our architecture, and is commonly known as the Tudor Arch, from being found in most of the buildings erected in the reigns of the two last Henries, or about the latter end of the 15th century; and it may therefore fairly be stated, that the present arches cannot be older than the date assigned for the introduction of that species of arch, to which they are similar, but have in all probability been erected since that time, as is clearly the case with regard to the arch of the centre opening of the bridge.

"Before closing this account of the bridge, we are led to inquire into the origin of its name, and the circumstances which gave rise to its being called the Bow, or Bow-bridge. Most writers ascribe the derivation to the resemblance of the arch to the form of a bow, then called *de Arcubus*, or the Bows. The description given by Stow, in his annals, goes to state 'the bridge was arched like a bowe, a rare piece of worke, for before that the like had never been seen in England;' and Grose observes, it might derive its appellation from the word *beau*, or handsome, an epithet very likely to be given to it in those days.* * * * *

"The piers for the support of the arches occupy a very large proportion of water-way of the river, and, like many other ancient structures of this description, are placed at an angle with the stream, causing interruption alike to the navigation and to the passage of the flood-waters.

"The width of the bridge was originally only thirteen feet six inches between the parapets, but in the year 1741 it was increased to twenty-one-feet.

"A few years previous to the bridge being widened, an accommodation had been made for foot-passengers, by projecting a wooden platform five feet wide over the piers on the north side; this has lately been rebuilt, at the expense of the two counties, after having been the subject of litigation for two or three years.

"Very little attention appears to have been paid to uniformity in building this bridge, as scarcely any two corresponding points in the structure agree. We find the springing courses upon different levels, and also the elevation of the arches above the surface of the water, besides which the two piers are unlike both in width and length.

"The side arches claim particular notice, from having a centre rib of considerable strength projecting below the line of the arch; a form of construction frequently to be met with in old buildings of this kind.

"The centre arch, which is without any rib, has evidently been rebuilt upon the remains of a former one, probably to meet the demands of an improved navigation, it being in its present state much better adapted for the passage of vessels than if formed after the model of the side ones, as it no doubt was before being altered, for the springing stones still remain.

"At this distant period it is difficult to determine with any degree of certainty the description of stone used in the original construction of the bridge. As in many other ancient buildings erected in this part of the country, Caen stone appears to have been used for arching, some of which still remains, while Kentish rag and Purbeck stone were employed in the inferior parts of the work. The present face of the piers consists of Portland and Kentish stone, laid in courses of various shapes and dimensions.

"Bow Bridge, unlike many of the old English bridges, has no starlings or projections beyond the line of masonry of the piers, which may be accounted for by the shallowness of the river at the spot; at low water, during the summer months, the difficulty of constructing the foundations could not have been great, as they are laid upon a stratum of gravel 3 to 4 feet below the present bed of the river.

"The filling-in of the arches between the face-courses and the centre rib is little better than rubble masonry, the stones of which are both rough and irregular in size, the joints wide, and in several places tiles are employed to wedge the whole together.

"The masonry of the centre arch is of a different character to that already described; the outside face-courses are also in two thicknesses, composed of Kentish rag stone, with a few of Caen stone, which no doubt had been saved from a former arch, while the filling-in between is entirely built of Kentish stone in regular courses very neatly put together, and, as already stated, without any rib or other projection.

"The external face of the bridge above the arches is formed of common rubble masonry, and the interior part over the piers and arches, no doubt filled up nearly to the level of the roadway with chalk or stone built in mortar, the plan generally adopted by the ancient builders in works of this description.

"The masonry of the additional arching, &c. made to the bridge in 1741, consists principally of Purbeck and Portland stone, built in regular courses in a firm and substantial manner."

After many years of unceasing endeavours on the part of the trustees of the road, an act of Parliament was obtained in 1834 for taking down the old structure and building a new bridge. As this was to occupy the same site as the old one, it became necessary to provide a temporary bridge for the public during the erection of the new one, and this was done by the erection of a wooden bridge across the river, near to the same spot, which was opened for traffic July 25th, 1835, and on the same day the old bridge was closed, and in a short time after "not one stone was left upon another" of that once celebrated structure, which Stow relates to have been "a rare piece of worke," at the period when he wrote.

The works of the foundation of the new bridge, on the Essex side, having been sufficiently advanced, the ceremony of laying the first stone took place on the 12th day of December, 1835. The stone was of granite about 5½ tons weight, in which was deposited, in a hollow made for the purpose, a glass bottle, containing a series of new coins, and a brass plate upon which was engraved the following inscription:—

Bow Bridge.

The old bridge over the River Lea, founded on this site by Matilda Queen of Henry I., having become inadequate for the increased thoroughfare by land and water, and a new bridge to replace the ancient structure having been resolved upon, this first stone was laid on XII December, MDCCCXXXV, by Emma, the lady of John Henry Pelly, of Upton, in the County of Essex, Esquire, F.R.S., Deputy Master of the Trinity House, and Chairman of Trustees of the Middlesex and Essex turnpike roads, assisted by the Committee of Trustees appointed to carry into effect the provisions of the Act 4 & 5 William IV., chap. 89, in relation to Bow Bridge.

COMMITTEE.

John Henry Pelly, Esq., F.R.S.
Chairman.

The Venerable Archdeacon Jones	James Graves, Esq.
Sir Thomas Barrett Leonard, Bart.	Richard Gregory, Esq.
Robert Westley Hall Dare, Esq., M.P.	Richard Hallett, Esq.
James Bridger, Esq.	John George Hammack, Esq.
Benjamin Brushfield, Esq.	John Hodgson, Esq.
John Burnell, Esq.	John Hubbard, jun., Esq.
John Carstairs, Esq., F.R.S.	William Maiden, Esq.
Nicholas Charrington, Esq.	John Milner, Esq.
William Cotton, Esq., F.R.S.	William Pearce, Esq.
William Davis, Esq.	Joshua Pedley, Esq,
John Drinkald, Esq.	Samuel Taylor, Esq.
George Fox, Esq.	John S. Thompson, Esq.
John Francis, Esq.	Edward Vincent, Esq.
John Hillson Giles, Esq.	

George Dacre, Clerk to the Trust.
James Walker, F.R.S., and Alfred Burges, Engineers.
Samuel Farey, Surveyor to the Trust.
Thomas Curtis, sen., and Thomas Curtis, jun., Builders.

The last stone of the arch was laid Jan. 31, 1838, by the chairman of the trustees, J. H. Pelly, Esq., F.R.S., &c. &c., when a bronze medal of Queen Victoria was deposited in the bed of the stone, inscribed upon the edge with the occasion, date, name, &c. &c.

The bridge was publicly opened on Thursday, Feb. 14th, 1839, by the Sheriff of Essex, William Cotton, Esq., F.R.S., &c., and a retinue of carriages driving from the Essex side, meeting on the centre of the bridge, the Sheriff of Middlesex, Alderman Thomas Wood, accompanied by the chairman of the trustees, and followed by a long retinue of carriages, containing the trustees, the engineers, &c. &c.

The form of the bridge, as shown in fig. 1, is a very flat segment, the rise not being more than three feet, and consists of an oblique arch of an elliptical form, the wing walls extending at each end of the bridge terminated with granite pedestals surmounted by lamp irons.

The following are the principal dimensions of the bridge :—

	ft.	in.
Span of arch, measured on the face	66	0
Span of arch, measured square with the abutment line	64	0
Rise of arch	13	9
Thickness of abutments	15	0
Length of bridge at wings	146	0
Width of bridge in clear of parapet	40	0
Width of carriage way	30	0
Width of each footpath	5	0

The arch stones are 4 feet thick at the springing, and 2 feet 6 inches in the crown.

The contract for the new structure, with the temporary accommodation for the public during the erection of the new bridge, is stated to be about 11,000*l*. The stone used for the external face is blue Aberdeen granite, backed with the masonry of the old structure. The foundations are laid upon a bed of strong gravel several feet below the bed of the river, and a protection of sheet piling is driven in front of the masonry several feet into the solid ground.

It was expected that in excavating the bed of the river, for the foundations of the new bridge, some antiquities would have been discovered, but in fact few articles of any interest were found, and those of trifling value. The most interesting were some brass tokens, two of which are more particularly connected with the subject before us; a few silver coins of little value, some ancient iron keys, with the remains of an iron spear head, nearly comprise the catalogue of all that was found.

We must not omit to notice that in the demolition of the old bridge it was found that the masonry of the arches was not originally covered by gravel, &c., to form a roadway, as it is now usual, but that the carriages and horses went directly upon the stone-work of the arches, and that ruts of the wheels had been worn in places to a depth of nine inches, and holes were worn through, evidently made by the tread of the horses.

ISOLATED HARBOURS OF REFUGE—EXAMPLES OF NATURAL FORMATION,

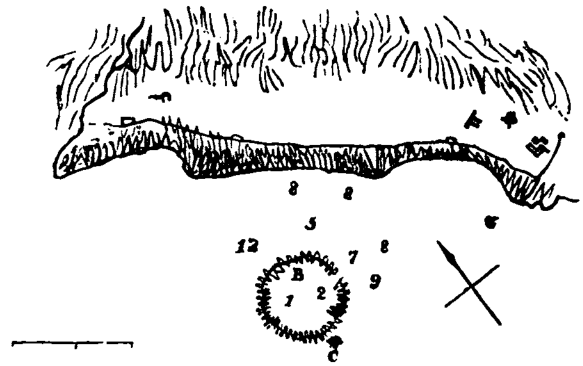
BY HYDE CLARKE, ESQ., C. E.

As I have strongly advocated, and I believe introduced, the principle of insulation as applied to harbours, it is not unnatural that I should take some interest in that of isolation, which is certainly one of the most important principles which has lately been elucidated. Its author, Mr. Tait, may congratulate himself on the acknowledgement of its merits which it has so generally received, and I shall be happy if the few remarks I now contribute should afford any additional reason for its support.

It is certainly augural of the advancement of harbour engineering, that instead of plans being merely confined to local circumstances, so much attention is now being devoted to the illustration of general principles; which, however, can only be drawn from nature. The importance of philosophical instruction to the engineer is powerfully inculcated when we see the manner in which objects, apparently so remote, are brought to bear upon our immediate pursuits. It is true, indeed, that this is a principle of philosophy, but it is one, the importance of which does not seem always to be recognised, although it should be remembered that even the abstract sciences are derived from the observation of natural phenomena, and that the laws of mechanics are equally developed in the motions of the heavenly bodies, as in the construction of the animal and vegetable kingdoms. The face of nature is, in fact, the great book of truth, written by an unerring hand; and it is upon the precepts there taught that equally in science, literature, and art, all excellence depends.

Mr. Tait has, indeed, informed me that it was from the Isle of Wight that he partially conceived the idea of his own plan, and upon that basis Mr. Rooke has also founded his modifications. To shew, however, that this is not an individual example, but part of a general rule, I now present some instances of natural isolated harbours, which, while they support the principle advocated by my two philosophical friends, may throw some inductive light upon the probable result of future operations.

Fig. 1.



PORTO DO ILHEO.

The figure B here inserted is the representation of an isolated harbour in active operation. It is called Porto do Ilheo, and is situated in the island of St. Michael's, one of the Azores, opposite the town of Villa Franca, and not above six miles from that of Ponte Delgada, one of the most important shipping places for the fruit and wine trade. From the nature of the basin it may be readily referred to a volcanic formation, and this is supported by its general configuration, as much as by its situation with deep soundings around it. It has all the appearance of an extinct crater; consisting of a wall of rock rising in most places 30 to 50 feet high, with a hollow centre, and an opening on one side. As nearly as I can recollect, it is about a quarter or half a mile across, and at low water has, in the centre, from eight to ten feet water, with a sheeting of mud covering the bottom. The mouth is to the north-east, of course opposite to the prevailing winds, and it is the only place in the islands which is sheltered against the westerly winds, but it is unprotected in the south-east when a heavy swell runs in its neighbourhood. The island is often used for careening, and it is the general place of refuge in westerly winds for the vessels from Ponte Delgada, which run here until the fury of the storm is abated, and lie without a wave to ruffle them, except that sometimes there is a dash of spray through a break in the west wall. Its importance was impressed upon me at the time I was engaged with the Atlantic Steam Navigation Company, the first which was brought forward in 1836, when my plan was to have used the Azores as a central station for communication to North and South America and the West Indies. The use of this island as a depot was strongly enforced upon me by a merchant captain well acquainted with it, and I proposed to have had it deepened and an entrance made, accessible at all times of tide.

All such cases, it must be remarked, are of volcanic formation, and the entrance is almost uniformly found opposed to the prevailing winds. No satisfactory account of the cause of this has, however, been given, and the reasons assigned by Lyell are far from clear or convincing. In the recess called Rowley Shoal, off the north-west coast of Australia, however, as described by Captain King, in Lyell's Geology,* where the east and west monsoons prevail alternately, the open side of one crescent-shaped recess, the Imperieuse, was turned to the east, and of another, the Mermaid, to the west.

In the Yellow Sea there is a remarkable horse-shoe volcanic harbour, mentioned in Macartney's Voyage to China, and the Chagos Isles in the Indian Ocean, described by Horsburgh, which have their openings to the north-west, are most important to navigators. These harbours are well known for their security, and ships can enter and depart with ease.

The Coral Islands, in Polynesia, are nearly all of this horse-shoe formation, so that of thirty-two examined by Captain Beechey (†), twenty-nine had lagoons in the centre, the land being merely a narrow ring. Some of these lagoons were as deep as thirty-eight fathoms, and the largest was thirty miles in diameter.

The following cuts represent a view of Whitsunday Island and a section.

* Vol. II., p. 233. † Beechey's Voyages, Part I.

Fig. 2.—View of Whitsunday Island.

Fig. 3.—Section of Whitsunday Island.

The channel leading from the sea into the lagoon is nearly always a deep narrow passage, which is kept open by the efflux of the sea at low tides. Lyell observes, that it is sufficient that a reef should rise a few feet above low water mark to cause the waters to collect in the lagoon at high tide, and when the sea falls, to rush out violently at one or more points. This, he remarks, is strictly analogous to that witnessed in our estuaries, (where a body of salt water accumulated during the flow,) issues with great velocity at the ebb of the tide, and scours out or keeps open a deep passage.

We see from these extended examples that Mr. Tait's principle is one that is neither unsanctioned by example nor useless in its results, although in the present state of science we have not perhaps the opportunity of carrying it out artificially upon the great scale which is exhibited to us by nature. The force of volcanic action, which can elevate reefs from the depth of the ocean, our greatest steam power cannot imitate; but the day may perhaps come when we may be able to employ this agent with the same ease that we do the strength of the ocean.

CURTIS'S RAILWAY IMPROVEMENTS.

We have before had the pleasure of recording several of Mr. Curtis's railway improvements, and we now add two others, well deserving the serious attention of all railway companies, for arresting those awful accidents, "collisions of trains," which, we are sorry to say, we see too often recorded in the daily papers to the injury of railways. We consider both contrivances admirably well adapted for the purposes intended by the ingenious inventor; they form part of several other improvements for which Mr. Curtis has recently received her Majesty's letters patent. In our next number we shall give some particulars of his other inventions. The following descriptions we extract from the specification of the patentee:—

A Break or Carriage for arresting the Progress of an Engine or Carriage, and which may also be applied for clearing the Line of impediments placed or lying upon it.—The best form of this brake is shown in fig. 1, 2, and 3; fig. 1 is a side view, and fig. 2 an end view of the same, it may be placed either in front as shown, or behind the engine or carriage; but I prefer the front of the engine, because it is made then to act as a means of clearing the line as above stated.

A shaft, F, is placed across the framing of the engine, and upon this shaft are fixed the two legs or levers, C C, and to the lower ends of the levers are attached the shoes, E. E., by the pins of the connecting rod, G., but in cases where the connecting rod, G., would not clear the timbering of the bridges of the line it may be omitted and the joints made by pins only; the cross-bars may be either omitted or placed higher on the parallel rods, D D, used to keep the lower surfaces of the shoes parallel with the rails, and to give them a certain degree of steadiness; the shoe is formed either of wrought or cast iron, or of timber shod with iron, with a flange upon its inner edge to correspond with the flanges of the wheels; the back end is formed to the curve of the contiguous wheel, so that where it is in gear it impinges against it, and the flange of the wheel enters the grooves formed in the shoe, and thus very materially adds to the stability of the apparatus. The groove is shown clearly in figure 3, which shows the upper plan of the shoe, and fig. 4 the under side of the same. A rubbing piece of wrought iron or other metal may be introduced into the under side of the shoe, and secured by rivets or other means, which can be renewed as it becomes worn out by the friction of the rails when in contact with them. A crank is fastened upon one end of the cross-shaft, F, to which is connected the rod, B; the other end of this rod is connected with the lever A, working upon a pivot, by which the engineer can work the brake as circumstances may require; the cross-shaft is connected by the carriage to the frame in the usual way, and the pin makes likewise the connexion of the parallel rod, D, at its upper end, and the pin at its lower end; the lever may be substituted by a screw, which may be made to act in a line with the connecting rod, B, for the purpose of working the apparatus, or any other fit and suitable leverage may be adopted. When the engineer observes anything upon the line he is desirous to remove with the brake, he depresses the shoes to within a very short distance of the rail, which distance may be denoted by a stop placed upon an arched segment, against which the lever, A, may work, or by any of the usual means for the same purpose, and when he is desirous to stop the engine he causes the brake to come into contact with the rails by moving the lever, A, further forwards, and if to stop the engine as short as possible, the lever is thrown forward until it occupies the place shown by the dotted lines, when the apparatus assumes the position also shown by the dotted lines in figure 1, the effect of which is to raise the engine a space equal to that included between the black and dotted lines.

The force required on the part of the engineer to produce this effect is very trifling, because the momentum of the engine forces the shoe into gear as soon as it is brought firmly into contact with the rails; the springs, by their re-action, still keep the wheels upon the rails, but the weight being transferred for the most part to the brake, the tractive power of the driving wheels is very much reduced, at the same time such an extensive rubbing surface is brought into action that it will be sufficient to bring the engine to a dead stop although the steam may not be shut off. It is evident by examining the figures that any degree of retardation may be produced between that necessary to bring up the engine and that slightly to check its velocity, as in descending inclined planes and by moving the lever more or less forward, and the leverage must be also sufficiently powerful of whatever kind it may be formed, so that the shoes may be drawn out of gear without stopping the engine.

An Apparatus to prevent Collisions between Trains on the same Line of Rails.—This apparatus is shown in figures 5 and 6. Figure 5 is a side view of the apparatus and an engine in contact with it, attached to the last carriage of a train, and figure 6 is a plan of the same.

The sledge or retarder, A, is formed like a wedge, with its superior end turned up upon the inner side; flanges are formed, so as keep it upon the rails, the two sides are united together by the cross-bar, J, the plate, K, and the cross pieces, G G, and the sides are set to the same gauge as the rails, so that an engine may run upon it without difficulty to the cross-bar, J; two buffers, D D, are fixed, which correspond with other buffers, I, formed upon the front frame of the engine, so that when the engine comes in contact with the retarder these buffers receive the concussion; the plate K is used, in order to unite the sledge as near to the point as possible, and still to allow a free passage to the flanges of the wheels; to the cross pieces G G, the spring pieces, B B, are fixed, which form shafts for the wheels C C, upon which the apparatus is carried when out of gear; E is a counterbalance weight to counterpoise the weight of the sledge, so that a man can move it along the line, like a truck, with great facility; the coupling F is formed for the purpose of connecting the sledge with the train in the usual way, by means of a joint and pin.

The retarder or apparatus, when out of action, and connected with a train, is attached to the last carriage, as shown at L; then the sledge rides above the rails, and is suspended by the spring pieces B B; but should an accident happen which would stop the train, one of the conductors immediately detaches the retarder, and runs back with it, and places it 500 or 600 yards behind the broken-down train; then, should not the engineer of the following train observe the train before him, and stop his engine, the engine would run into the retarder, and would become a sledge; the driving wheels, if not stopped by the great resistance which would now be opposed to them, would skid round in the retarder, and would have no power to move forwards. No violent concussion would take place, but the engine would slide along a certain short distance in the retarder when the train would be brought to a stand-still; a hanging frame, K, must be formed from the engine frame, and the buffers usually placed upon the head board transferred to the lower frames, or other buffers I, placed there. As I do not consider it would be the best plan to make the superior end of the retarder, A, so high as to meet the buffers placed on the head board in the usual manner, the flange of the sledge A may be either continued all along, as drawn, or may be made in detached pieces at certain intervals in the length, as may be found the best. In the case of a swift train overtaking a slow one in a fog or at night, the swift engine

would run into the retarder, and the same effect upon the engine and train would be produced as before stated—viz., that it would be brought to a stand, and the only effect produced to the slow train, behind which the retarder was travelling, would be, that it would be torn away from its fastenings; for the purpose, therefore, of meeting a case of this nature, it will be advisable to make the fastenings such, that it may be torn away without the last carriage being subjected to any violent shock, with this view the pin at F may be of oak, or hard wood strong enough to drag the retarder, but sufficiently weak to give way in the case mentioned.

CIVIL ENGINEERING EDUCATION AND REWARDS.

In our last volume, p. 369, we were induced, under this title, to give an answer to the many fallacies which were then afloat on these subjects, and particularly to the misrepresentations of writers in the *Times* and *Athenæum*, by refuting the theories founded on the Polytechnic School. Not one of our arguments has been contradicted, and in no other periodical has any reply been attempted. The article has created some sensation, and we should not have recurred to the subject, having, in our own opinion, said enough to settle the question; but we have received so many letters respecting it, that out of deference to our correspondents we cannot avoid resuming it.

We particularly objected to the notion that engineering education could be taught only in schools, and expressed our conviction of the impolicy of separating it from the present system of practical instruction in the offices of engineers. We have thus unwittingly knocked on the head the favourite crotchet of some of these writers, and we have received a volley of letters in abuse of our arguments, but not in refutation. The following takes a higher stand, and out of respect for the writer, we give it at length, curtailed only of an exordium giving a long definition of criticism:—

Sir,—I cannot refrain from expressing both surprise and regret at finding, in more places than one of the "Civil Engineer and Architects' Journal," an attempt to show that engineering instruction is either unnecessary in this country, or that it is sufficiently provided for. Both assertions are equally erroneous. I need only advert to numerous instances of failure in engineering works, too well known and too severely felt by the parties concerned in them, to show how absolutely inadequate is the knowledge of our civil engineers generally, and how necessary it is that those who intend following that important career be adequately instructed; and I need only observe that the faculties established at Durham, and in University and King's College, are, though eminently useful, but secondary objects in those establishments, to show that engineering instruction is very far from being sufficiently provided for in this country. I am not one of those who are disposed to see everything good that is done abroad, and everything bad that is done at home; but equally do I deprecate that erroneous and narrow-minded prejudice which sees perfection in all that is English, merely because it is so, and can find nothing but sneers and ridicule for the finest establishments of other countries, because they are not English. The man who would endeavour to ridicule the Polytechnic School of France, must be the veriest—but no, as Peter Pindar has it, "at calling names I never was a dab."

I will not make invidious comparisons; I will argue the point of engineering education on other grounds. It has been said, that "the English student derives his knowledge from private study in books, and not by oral instruction from professors." I confess I had yet to learn that our English youth were so passionately fond of study as to require no teaching. It is elsewhere said, "if science were only to be gained from the dictates of professors, we should indeed be in a state of mental degradation;" and pray, I would ask, what are the books from the private study of which our youths are to become such perfect adepts, but the dictates of professors? Has the writer of such senseless sentences received no benefit in his lifetime from oral instruction? If so, he must either be very ignorant or a natural prodigy.

In the article on civil engineering education, to which I allude, there is a flaming paragraph setting forth our superior excellence in all things, which, as having nothing to do with the point in question, would have been much better omitted; to praise ourselves is fulsome and undignified. The writer goes on to state, "To whatever department we direct our search, it will not be very easy to find any symptoms of inferiority in the working of our present system." Indeed! It is easy to see the writer has had none of his capital engaged in the thousand and one speculations which have failed for sheer want of the very first elements of scientific knowledge. Again the writer falls into a comparison between France and England, in which, according to him, France has few or no great works. Were we so disposed, we could presently show him his very egregious mistake. Nay, let alone France, we could point out in other countries, countries we are disposed to despise as barbarous, works equal in beauty, magnitude, scientific combination, and practical skill, to anything we can boast; but we repeat it, we will institute no comparisons.

That we have many, very many magnificent works no one can or will attempt to deny; but what does this prove? That if we have been able to effect so much without the aid of special scientific knowledge, we may fairly hope to achieve the greatest things if a proper system of instruction be introduced.

Will any man be bold enough to say that the payment of a 1000*l.* to some celebrated engineer or architect, and that five or seven years "copying and transcribing in an office" are sufficient to qualify a young man to become a civil engineer? I appeal to the writer of a paper in the "Civil Engineer and Architect's Journal," page 159, vol. I.; I appeal to every man of common sense. Is any one absurd enough to imagine that an engineer or an architect of first rate eminence, whose every moment is employed in his professional duties, can by any possibility devote any portion of his time to the instruction of the pupils placed under him? or is any man disposed to think himself unfairly treated because such instruction is not given to his son? Is it not an acknowledged thing, a tacit understanding between parties, that the 1000*l.* paid to Mr. A. or Mr. B. is solely for the privilege of saying my son was in Mr. A.'s or Mr. B.'s office, and nothing more.

But will any one be so doggedly ridiculous as to maintain that such a system is all-sufficient for the education of our civil engineers, and that too at a moment when the amazing increase of industry calls loudly for a whole host of fully competent engineers?

The English mechanic, it is said, "has no Ecole Royale to frequent, and no Conservatoire des Arts et Metiers in which to exhibit his performances, but he can study in his own house, has his own periodicals, can learn from his brother workmen, and frequent a Mechanic's Institute in every town, while he has the free-born spirit of the English race to direct him, and the statue of Watt to remind him how his fellow countrymen can appreciate his labours." To call this anything but ridiculous bombast would be to misname it.

If the English mechanic has not the various advantages above stated, so much the worse, so much the greater shame to this rich and industrious country. As for the mechanic's study in his own house, it amounts to very little at most, and instruction from periodicals to still less. His brother workmen, with a few honourable exceptions, are little disposed to teach him anything but the way to the gin-palace, and nine times out of ten he understands not one word of the lectures given at the so-called mechanics' institutes; and as for his free-born spirit, it directs him in too many cases, alas! to little else than to rail at all above him, and at the institutions of his country. Finally, as for the statue of Watt, I would like to know how many have seen it, and how many from the contemplation of it have risen in their career.

But now come we to the point. Hitherto we have been told that instruction, other than private reading of books, is useless; that without any systematic education we have done wonders; but now we have a recommendation of the course proposed by the English colleges, and, despite the ridicule just thrown upon oral instruction, we are now told that "the practice of the students attending philosophical lectures will prove an important help to their professional education, while we are to deprecate any attempt wholly to educate them, whether in an English academy, or the Ecole Polytechnique itself, which might turn out a very good surveyor's hack, but which would not be very likely to produce a Smeaton, a Brindley, or a Watt."

Now, Sir, I would ask—not to advert to the preposterous idea that the instruction of such men as Monge, Biot, Francœur, Hatchett, La Place, Legendre, La Croix, Prony, Hassenfratz, Fourcroy, Bertholet, Chaptal, Gay Lussac, Thenard, &c. &c., can only turn out surveyors' hacks—what, I would ask, is all this but the puff direct of the classes of civil engineering lately established in some of the English colleges? —the puff exclusive—the puff ridiculous, inasmuch as contradictory of what was before advanced—the puff mischievous, as it deprecates the only means by which solid instruction can be given in civil engineering —viz., special tuition in an establishment organised solely for the purpose of creating efficient engineers. None ean see with greater pleasure than ourselves, that attention is being directed to the necessity of particular instruction in civil engineering. The establishment of the classes alluded to, sufficiently disproves the assertion with which the writer of the article we are commenting sets out. Too long, indeed, have we been guided by dear-bought experience and expensive blind experimentalizing. It is high time that theory, which is nothing more than the results of the best practice, methodised and reduced to axioms, be combined with practical operations to enlighten them, while practice, in its turn, points out the possibility of fresh improvements, with this advantage, that by a knowledge of scientific truths they are founded on certain principles, and are not derived from vague and indefinite conceptions.

Indeed, the necessity for scientific knowledge is forcibly pointed out in an article headed "Mining and Mines," in the "Civil Engineer and Architect's Journal," p. 419, vol. I; and what is essential to miners must be still more so to the civil engineer; for mining is but a part—a section—of the attributions of the civil engineer, whose profession extends from the laying down of a gaspipe to the construction of a jetty; from the fixing of a crane to the construction of a locomotive engine; from the paving of a court-yard to the construction of a railway; from the tracing of a drain to the connexion of seas by a canal; from the building of a porter's lodge to the erection of the most extensive manufactory; from the draining of a cellar to the draining of a country or of a mine. His knowledge must be general as his labours are multifarious. Of minerals, metals, and vegetable substances, he must know both the nature and the use; the chemical and physical properties and actions of bodies, he must be intimate with. He has to employ forces of every kind, and must hold them under his control, which he can only do by thoroughly understanding them. In a word, his knowledge must not only be general, but perfect, as ignorance in any one correlative object paralyzes or counteracts the effects of his knowledge in the rest. Can this be denied? and will any one, in the face of such truths, maintain that science is unnecessary to the civil engineer, or that it is amply provided for among us? The preface of the "Civil Engineer and Architect's Journal" contains an enumeration of several establishments as teaching civil engineering. In every one of these, certain branches of engineering knowledge may be taught: indeed, it is hardly possible to teach any thing with which the civil engineer should not be acquainted, but we have no such thing as special schools for civil engineers. Particular classes are highly useful, no doubt, as auxiliaries, and we are happy to see them established; but to say that they are sufficient, or that more adequate knowledge is likely to result from such unconnected, and, therefore, imperfect studies, than from a regular course in an establishment where all the elements of a good engineering education are combined, where all the efforts tend to the one main point desired, would be to say an absurdity too palpable to be for a moment dwelt upon.

In conclusion, sir, I will merely observe, that engineering education is, with us, wofully deficient; that, at no period was it ever more loudly called for; and that, judging by what has been effected without it, we may fairly anticipate incalculable benefits when proper scientific instruction shall guide our practical skill. Let schools, then, be established, and let us not, to favour any particular interests, dissuade the public from a "consummation so devoutly to be wished," as the establishment of special schools for civil engineering.

I am Sir, yours, &c., * * *

We pass over the reflections in the above letter on ourselves, for we feel conscious of having done our duty to the profession, and the *magis amicus* truth; as to any assertions of venality, it is unnecessary to protest against them when our venal arguments remain unanswered; but we can assure the writer that we are neither shareholders in the universities, nor interested in the professors' fees, and that, still more, we are not on the look out for a berth in any college, to be or not to be.

We are next assured that the man who would endeavour to ridicule the Polytechnic School must be the veriest, (*magnus hic deflendus hiatus*,) but no! as Peter Pindar has it, "at calling names, I never was a dab." Now, we never ridiculed the Polytechnic School at all, although we are not aware what sacred protection it should have in the eyes of Englishmen. Then it is asked—what are the books from the private study of which our youths are to become such perfect adepts, but the dictates of professors? We never said that they were not, or that the dictates of a professor on proper subjects were not of use, but we feel indebted to our correspondent for this argument in favour of the use of books. By and bye he assures us, that he can negative our comparison of the inferiority of French public works, and hints something about a barbarous nation. We can only assure him that we should willingly have received the refutation, and paid equal attention to it. We next learn an important fact, that engineers' pupils are not expected to learn anything, but only to pay their money. The writer then introduces a political declamation against our English mechanics, which every man of experience can contradict, and in reply to which we can do no better than recommend him to study that amusing work, "Hints to Mechanics," by Mr. Claxton. We never said that instruction, other than the private reading of books, was useless and consequently need not advert to such a gratuitous assumption. We have read with due attention the long muster-roll of names, almost equalling the enumeration of Homer, and we give full credit for the industry in assembling all the names of professors, living or dead, that could be found; the names are very good, certainly, and include many eminent chemists, mathematicians, astronomers, philosophers, &c., but we should like to know how many engineers? We can find plenty of colleges in England to furnish a list of well-known names, but we do not see what that has to do with engineering. The writer then falls into a farther mistake, when telling us that special tuition must be given in an establishment organised solely for the purpose, he instances the Polytechnic school, believing that it is entirely devoted to civil engineering. By referring to our first article he will, however, see that it is no such thing. The concluding definition is also rather loose; it informs us that duties of civil engineers are to construct locomotive engines and build porters' lodges, and manufactories. We always thought that such things belonged to the practical engineer and the architect.

We shall now enter into a farther consideration of the subject, and shall first endeavour to ascertain how far the nature of the profession of a civil engineer influences his education. It appears to us that the course pursued in one profession does not necessarily involve its application in another, but that each requires a system adapted to its peculiar pursuits. If we correctly understand the question, civil engineering is essentially a profession of genius, having to deal with many new and unforeseen cases, and that as decidedly as any branch of the fine arts; it is therein distinct from law and medicine, which are principally systems of the application of old processes. No one by force of genius could become a lawyer, and it would be very difficult in the same way to obtain a qualification for the practice of medicine, although the study of physiology affords opportunities for the exercise of the exercise of the higher faculties of the mind. Genius we consider to be the ground-work of civil engineering, and the means of carrying out designs are derived from general philosophical studies and the use of technical processes. All these are intimately enwoven together, in the same manner as in painting. Genius must be united with the mechanical handling of instruments; as in architecture the conception must equally be instructed to be carried out in the treatment of style and its adaptation in construction.

For the attainment of this practical instruction we imagine no man of sound judgment would prefer a school to an engineer's office, while to engraft education upon a theoretical instead of a practical basis, or to consider practice as merely the handmaid of theory, instead of its parent, would be undoubtedly to destroy all the advantages which we now so eminently enjoy. It is an error among pedants to substitute theory as superior to practice, instead of remembering that theory is only a classification of the results deduced from it, and that practice in engineering holds the same rank with regard to theory as the observation of phenomena does in philosophy. It would be a similar error in politics to consider laws as existing before the population from which they arose, and it is from one of these pedantic conceits, in supplanting language by grammar, that the study of literature is so much thwarted in modern education. Theory, like practice, properly speaking, is only the representation of one faculty of the mind, and does not constitute the whole; practice resembles perception, and theory is an extension of the power of abstraction and generalization.

As to the instruction in theory, it must be remembered that facilities exist in England in the shape of private teachers and scientific institutions, which the system of universitary police does not allow in France and other parts of the continent. There, consequently, theoretical instructions must be given wholly in public establishments, or it is difficult to introduce it as an accessory to practical studies. The way in which we look upon the collegiate classes in England, is only as they resemble and supply the place of that system of instruction which already exists, being rendered subsidiary to the general course of education.

To show that the views which we entertain, however erroneous, are not without some support from other members of the profession, we shall refer to the view entertained by the Institution of Civil Engineers. In their regulation for the admission of candidates, they expressly recognise the force of native genius, "which commenced the profession with a Brindley and a Smeaton, and was in our own time exemplified by a Rennie and a Telford." They proceed upon the basis of considering practical instruction as the groundwork of the profession, and require from candidates that they should either have served the usual time of pupilage, and then had subsequent employment for five years, or else that they should have practised on their own account for five years, and have acquired considerable eminence. What great names would English architecture be able to produce, had they excluded Wren, Aldrich, Vanburgh, and so many others? Where would the arts have been without those names which have sprung from the ranks of genius, a higher school than all the academies which were ever founded? Schools are limited, and genius is widely dispersed; so that the more you restrict your boundaries, the less chance you have of acquiring great men, and the greater certainty you have of falling into that general decay which the mannerism of schools and restricted competition produce.

The present proposals of giving a preference to theoretical instruction are peculiarly ill-timed, when it has been so strongly felt in other cases that a greater attention to practice was the only sure guide to eminence. It is well known that the medical world are strongly inclined to abolish the unnecessary distinction between physician and surgeon; and that they are more than ever convinced of the importance of the preparatory instruction acquired in apprenticeship. As to the idea of making civil engineers in colleges, it is one of the most preposterous which ever entered the head of a theorist. We know what has been the success of attempting this system in the fine arts, and we can see what a plentiful crop of daubing mannerists it has produced. We may thus form some idea of what would be its result among the civil engineers; there would be no lack of them, certainly, but there would doubtless be a terrible deficiency of talent and a great abundance of mediocrity. There is one defect attendant upon collegiate education, which has done that to damp the energies of students which no other exertions have been able to remedy. Collegiate instruction soon becomes so expensive as to come only within the range of a certain class; and while the selection is thus limited, the effect on the students is, that often possessing a competence, they have no other ambition than to pass through their course with as little trouble as possible. It must be conceded, on the other hand, that collegiate instruction effects a considerable saving in time; but it should be remembered, that self-study, like a mechanical power, makes up in strength for what is lost in time. Even in professions where knowledge is communicated by lectures, the benefit of individual instruction begins to be appreciated, and in the opening speech, last session, of the Dean of the Medical Faculty, at King's College, he strongly recommended this course to be adopted. The idea of teaching civil engineering solely in colleges we cannot but look upon as absurd, and we know no means of expressing our views more strongly than by repeating the words we used in the preface to our last volume.

"The system of teaching by lectures, it has been found by experience, cannot successfully inculcate every thing; and while it has been abandoned at our older universities, in medical studies it is accompanied by demonstrations and clinical instructions, such as can never be applicable to mines or engineering. We can have no dead railways to dissect, no prepared veins and lodes to illustrate; and although construction may be partially learned from models, yet it is in the open field of practice that its application must be acquired."

MEMOIR RELATIVE TO THE COURSE OF THE SHINGLE ON THE COASTS OF SUSSEX AND KENT, AND THE LAWS BY WHICH IT IS GOVERNED.

By J. H. Williams, Lieut. Colonel, Royal Engineers.

1. The general bearing of the coast from Beachy Head to the South Foreland, is from W.S.W. ½ south, to E.N.E. ½ north, by compass.

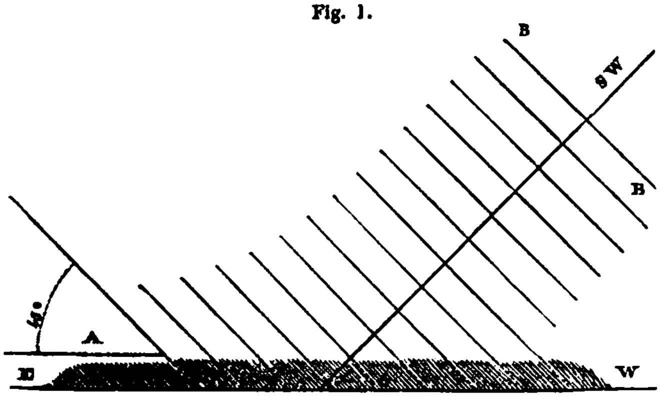
2. Shingle of a similar kind, produced by constant detrition of the Beachy Head Cliffs, and augmented by detritus from the Kentish Cliffs, is found in large quantities all along the shore from Beachy Head to the South Foreland.

3. It is ordinarily drifted along the shore from the westward to the eastward, though subject to occasional interruptions.

4. Wind and wave are the principal propelling powers. The latter closely follows the course of the former, though at times deflected somewhat more southerly; and a light air and undulation are sufficient to carry the shingle in an opposite direction to a strong tide.

5. The shingle is invariably borne along in the direction of the acute angle, which the waves form with the shore; and the drift is more or less rapid, in proportion to the strength and direction of the wind, and the height and velocity of the tide.

Fig. 1.



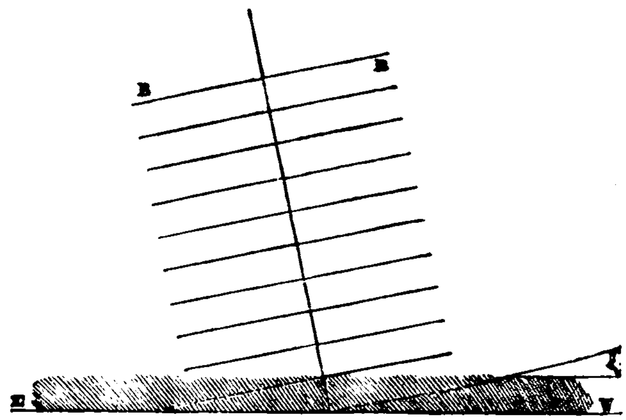
The Shingle borne to the Eastward.
A, Angle of Wave, 45°. BB, Line of Wave.

6. The easterly and wonted course of the shingle is the effect of the great prevalence of westerly winds in the English Channel. The quantity put in motion, and the rate at which it is borne along, are greatest on the Hastings shore, in a gale from the south-west, accompanied by a spring tide, when the wind and sea impinge on the shore, at an angle of about forty-five degrees (see fig. 1).

7. When the wind blows from the eastward of south, a motion of the shingle to the westward is speedily perceptible, and in a gale from the south-east considerable quantities are moved in a westerly direction.

Fig. 2.

S. by E



The Shingle borne to the Westward.
BB, Line of Wave.

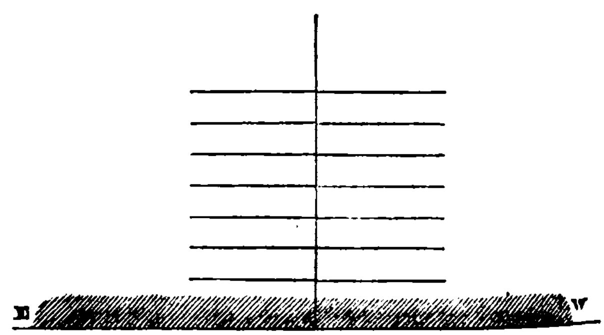
8. When the wind sets directly on or off the land, the shingle is quickly laid in ridges parallel to the shore, and there is no indication of any drift of shingle along shore at such times. The truth of this view of the subject will scarcely be doubted by any one who will carefully watch the action of the shingle about a groin perpendicular to the line of shore.

9. The foregoing data clearly prove that the motion of the shingle is strictly governed by the direction of the wind and wave, and as these prevail from the westward for nearly nine months in the year, and storms are most frequent from that quarter, it follows that shingle must be carried to the eastward in great excess.

10. The force-propelling beach to the eastward may be considered to be exerted between the west-south-west and south-by-west points; and therefore allowing for an action of the wave somewhat more southerly than the wind, no harbour on this part of the coast should be open to any point of the compass west of south, nor should the relative positions of the pier-heads be such as to receive the set of the sea between south and west.

Fig. 3.

South.



The Shingle is moved up and down the Slope, but is neither carried to the East nor to the West.

11. Any projection of magnitude must cause a permanent alteration in the form of the adjacent shore. The utmost care should therefore be taken, in carrying out a pier or breakwater, that the new line of beach may lay as nearly as possible at right angles to the point of the compass from where the wind blows, that causes the greatest drift of shingle. By such a disposition, the most effectual counteraction will be given to the easterly passage of the shingle that can be obtained; but if this principle cannot be fully carried out, let the nearest approach be made to it that circumstances will permit.

12. A chart upon a large scale will show that there are inflexions of the coast where shingle must be heaped up, and cannot drift, at the very times where it is borne along the general line in the greatest quantities. The shores on each side of the Point of Dungeness are examples. The extension of the Point to seaward, and its enlargement, may, it is presumed, be adequately accounted for by the theory advanced in the preceding remarks; and, assuming such to be the fact, a very decisive corroboration of the system here propounded is obtained.

RALPH REDIVIVUS.—No. XV.

THE YORK COLUMN.

The aspect of the planets happens now to be so favourable, if not to monumental columns at least to discussion relative to them, that perhaps I cannot possibly do better than make choice of the York column for my present subject.

Notwithstanding the force of classical authority it seems now to be admitted by a great many that an insulated pillar, more especially one borrowed from any of the orders employed in the construction of buildings, has no very great propriety to recommend it, it being offensive, because quite unmeaning, when detached from that of which it forms merely a portion, and apart from which it is consequently no more than a fragment, while, as the support of a monumental statue, it is most injudicious, because it necessarily elevates the figure so greatly that little is to be discerned of it, except its mass alone. Neither can this inconvenience be counteracted by increasing the size of the statue, because the column itself must be increased correspondingly, or else the other will appear out of all proportion to it, and extravagantly large. Thus in order to be properly seen at that height from the ground the statue of the Duke of York ought to be, at least, twice its present dimensions, more especially as, so placed, the object requires to be viewed at a distance exceeding its elevation from the ground, since otherwise it will be beheld too much foreshortened.

In regard to the column itself, it is the least eligible that could have been made use of for such purpose; because so far from having anything whatever to recommend it as an ornamental object it is utterly destitute of embellishment, not very pleasing in contour, and what few mouldings and members it has serve only to make us feel all the more sensibly the extreme dryness, stiffness, and poverty of the ensemble. Capital it can hardly be said to have any, the part intended as such finish being little more than a clumsy-looking square platform with an iron railing, above which the shaft of the column is continued, forming the cippus or circular pedestal, on which the statue is placed. The rails just mentioned may be termed light, but then so far from contributing to the idea of lightness, in the favourable sense of the term, they rather produce actual paltriness of appearance, having no more dignity nor beauty than the wires of a birdcage. Surely, in such cases, where an external gallery above the column is made a *sine qua non*, it would be infinitely better to deepen and hollow out the abacus itself, making its sides answer the purpose of parapets; or, which would be still better, there might be a gallery within the capital, the latter having ornamental apertures sufficiently large for a person to put out his head and look down while standing in perfect security. Certainly an external gallery, unless masked so as not to show itself, is a blemish, and in itself rather adds to than at all diminishes the general solecism of employing a column where it seems a tower is wanted. Otherwise than as a belvedere, from which the surrounding prospect may be beheld, a gallery upon the abacus is useless; for as to seeing the statue itself from that situation it is perfectly out of the question, while it requires some degree of nerve to attempt to get a glimpse of it by leaning back against the railing.

Another great disadvantage attending the practice of surmounting a monumental pillar by a railing, which though slight even to paltriness in itself gives the capital a strangely encumbered look, is that it requires the statue to be raised much higher above the capital than there would else be occasion for; and it would, I conceive, be greatly better in all such cases were the figure raised no higher above the capital than what would allow the whole of it to be seen from below, under an angle of 45 degrees, or, perhaps, somewhat nearer. Instead of being hoisted on an excrescence built up above the capital, the statue would then appear to stand almost immediately upon the latter, which it ought to be made to do as nearly as possible.

Although comparatively unimportant as to size, how imposing as to character and effect are the two granite pillars on the Piazzetta at Venice, and how greatly would their dignity be impaired were they surmounted by anything besides the figures they respectively support. In fact, those are veritable columns; not hollow constructions, made to resemble them, but solid monolithic pillars, and inferior only, perhaps, to such enormous monoliths as Pompey's Pillar and the Alexander Column at St. Petersburgh, whose heights are respectively 80 and 84 feet, but the latter of far greater magnitude than the other, owing to its diameter being so much stouter.

Whatever be its appearance to the eye, a tower built to resemble a column can hardly affect the imagination so strongly as a solid shaft of equal or even lesser dimensions; it would, therefore, be perhaps advisable not to let the hollow shaft proclaim itself as such, but to omit, as far as possible, every indication of its being so, and not to let it be seen that that it is a lofty circular tower, surmounted by a square, overhanging platform. If there must be an abacus, or something answering to it, surely, instead of the usual square member, it would be better to substitute a circular one. In columns, the square abacus has great beauty and and propriety, its office being to afford a broad surface, on which the architrave rests; but, with regard to a monumental pillar, the case is widely different, that having no horizontal mass to sustain. I may here quote Hosking, who speaking of the Monument and the lofty shot-tower by the south-west angle of Waterloo-bridge, says—"They are both of cylindrical form; but the one is crowned by a square abacus, and the other by a bold cornice which follows its own outline (i. e., of the tower); the greater simplicity and consequent beauty of the latter, is such as to strike the most unobservant." The contrast here objected to between the shaft and abacus, is certainly not unpleasing in itself, quite the contrary; yet although such combination is both agreeable and appropriate, where the abacus is no more than a member of detail, it becomes almost an incongruity, when the whole is so magnified that the single square stone slab placed on the column to receive the architrave, becomes a terrace or platform, whose angles overhang the the circular structure on which it is raised.

The utmost that can be urged in extenuation of such enormity is, that it is in strict adherence to classical precedent. The York Column, however, might very well have been allowed to deviate from precedent in that respect, since it differs most widely from its prototype, precisely where resemblance to it would have been a merit—namely, its monumental character as an historic trophy. While it is, architecturally, an imitation of the Trajan column, it is utterly devoid of all that gives magnificence and grandeur to this latter; neither does it offer anything whatever in lieu of the embellishment thus omitted by wholesale. Instead of having anything ornamental in its character, of displaying richness of any sort, or in any degree, it is stamped by the most chilling blankness, the most parsimonious plainness. Consequently, it is little less than a positive absurdity; for surely absurdity it must be allowed to be, to erect what, as a structure, is perfectly useless, and, at the same time, mean, and so far disgraceful as a work of art. Yet ugly Brobdignagian columns of this description are now stuck about in many parts of England and Scotland; and Glasgow and Edinburgh have their full share of them. To say that we build as fine things of the kind as the funds raised for them will permit, is no excuse, although our inability to erect anything better than what we hitherto have done, would be a most sensible plea for not building anything of the kind again. Nothing is more contemptible or more ridiculous than the blundering mixture of prodigality and parsimony we generally witness on similar occasions. With just enough to provide a statue and its pedestal upon a scale of grandeur, our ambition is satisfied with nothing less than hoisting up the figure, and perching it upon a gawky, unmeaning column, as plain as a post. Supposing the shaft of such column to be fluted, that does not at all mend the matter; because, when so preposterously enlarged, the fluting itself becomes only an absurdity. Almost as well might we think to decorate the front of a building by striating or fluting it with channels, as to adopt them quite contrary to what taste or propriety would naturally dictate, for a cylindrical shaft forming a slender tower; surely the far more sensible mode would be, to form narrow, slightly projecting *striæ*, having the appearance of strengthening the shaft, instead of scooping out hollows to weaken it.

As far as the York Column is concerned, no fault of the kind can be alleged against it, it being *totus, teres, atque rotundus*, without channel or wrinkle, hollow or projection to break the uniformity of its surface. It is perfectly innocent of fancies or whims, of bas-reliefs, twisted *à la* corkscrew, after the fashion of both Rome and Paris; that is, of the Trajan and its two imitations, the Colonne Vendome, and the Colonne de Juillet.

So far from having any decorations, it has nothing whatever to indicate its purpose. To be sure, there is a figure on the top of it, which may be that of the Duke of York, but then it might serve as well for the Duke of Wellington, or for Sir Walter Scott, since there are no symbols nor other marks by which this monument can be recognized as that of a military man. But what most of all surprises me is that those fastidious critics who discern such outrageous absurdity in the fine campanile of St. George's Bloomsbury, on account of the statue which forms so picturesque and graceful a termination to the whole mass, can so quietly put up with the infinitely greater absurdity of sticking what is not intended as an ornamental accessory, on the top of a pillar, without any pretensions to beauty in itself, and erected, it would seem, merely, that the effigy of the person so honoured, may be seen to the utmost disadvantage. Wherefore their taste should be so excessively scandalised by the lesser absurdity of the two, it is for them to explain.—But stop; a young critic, only five years old, at my elbow, has solved the mystery, by observing—"How very funny to see a man on the top of a church, where you know they always put a *weathercock!*"

CANDIDUS'S NOTE-BOOK.
FASCICULUS III.

"I must have liberty
Withal, as large a charter as the winds,
To blow on whom I please."

I. I do not know how our scrupulous copyists of Grecian architecture can reconcile it to their consciences, or to their taste, to omit, as I may say they are in the habit of invariably doing, those decorations that enter into an order, which, if not absolutely indispensable to the building itself, are, nevertheless, quite as essential to the effect and character of the ensemble,—or I might say, very far more so than those subordinate mouldings and other niceties to which such extreme —even superstitious—attention is paid by them. Like many other folks they strain at a gnat, yet can swallow a camel. Therefore, though they would deem it absolute heresy to make any alteration in the form of a base or a capital, they allow themselves to leave out what, not being uniformly the same in all specimens of the same order, is not considered as inseparably belonging to and forming a part of it. Look at any or all our modern imitations of the kind, and you will find them, almost without an exception, entirely to lack that richness and finish which the buildings of Greece itself exhibited, and which, so far from being at all superfluous, are indispensable to the due effect of the style itself, since deprived of those qualities, it becomes one chiefly marked by both disagreeable baldness and monotony. At first, perhaps, it might be considered a sufficient achievement to produce fac-simile copies of Greek columns; but the time is now past when any degree of merit can be imputed to such feats. They have ceased to be prodigies—in fact, have begun to pall upon us—yet we still persist in continuing the same mill-horse round, without advancing a single step. Is not our Anglo-Grecian architecture precisely where it was when we first took it up? Do our later works in it manifest greater mastery over it—such increased knowledge of its æsthetic principles as to be able to proceed with the the same spirit and feeling, wherever we are at a loss for actual precedent in the models furnished by Greece itself?—or rather, are we not as bungling tyros and apprentices just where we were at first? *Circumspice:* let any one compare some of our first attempts in that style with some of the last, and prove, if he can, that the latter exhibit great mastery over the same elements of design.

II. It is very possible for a building to be free from any thing that can be alleged against it as a positive fault; it may, to a certain degree, be even pleasing, and yet so far from being particularly creditable to its author, may chiefly serve to show that he is devoid, not only of invention, but of the ability to communicate any thing whatever of spirit and expression to his design. It may be correct, but then it is also *géné.* It resembles a lesson got by rote, or, as it is generally termed, got by heart, although except when a man's heart happens to lie where his tongue should be, the heart has no concern in the matter; which seemingly very impertinent remark is here *apropos* enough, for I mean to say that there is no heartiness, no cordiality, no feeling in such lukewarm productions.

III. I met the other day with an account of St. Andrew's Hall, at Norwich, which describes it as "a neat, grand, and elegant" building. Neat and grand! In the name of fire and water, oil and vinegar, cat and dog, were ever the two epithets so tacked together before? In addition to which odd character given of the architecture, we are further enlightened by being told that the columns are all uniform, "being covered with lead!" If that be true, no doubt they are very extraordinary columns, but how they should on that account be more uniform is not explained. *Quære:* Was not the writer thinking at the time of his own *columns,* which seem to be overlaid with plenty of that metal?

IV. Of my contributions to the Architectural Magazine, the "Literary Gazette" is pleased to say that I am "clever and caustic," than which I desire no better praise. I abominate your water-gruel style of writing, fit only for literary milksops and those excessively cautious "by your leave" gentlemen, who invariably make use of the most sugary expressions. Palatable or unpalatable medicine must be administered, and should the patient's case require bark it is of no use attempting to render it agreeable by mixing it up with flummery. Yes, but some folks cry out, your bark is sometimes downright *barking.* Assuredly; and, after all, one had need have the three heads of Cerberus himself to bark loud enough and long enough to produce any effect—to rouse up the sluggards and the slumberers, the good people who sit comfortably dozing and nodding over art, though all the while tolerably wide awake to—their own interest.

V. It is greatly to be wished that some of our Greek architects would bite some of our Gothic ones, because, in that case the latter would no doubt also become infected with that scrupulous precision and preciseness which constitutes the *rabies* of the others. Yet no such rabies discovers itself in the rage for Gothic architecture. *Tout au contraire,* your modern Goth makes no scruple of paring down the mullions of his windows until they are scarcely thicker than the bars used to be in our old sash frames. But your Greek will not bate you a hair's breadth in any one of the dimensions of a column: he is as inflexible on that point, as Shylock himself in regard to his bond. Perhaps I shall be told that, for such matters of detail, no such strict rules have been laid down for the Gothic style, as for the other; assuredly not; but then it does not exactly follow, that, because there are no precise rules, there are neither any laws whatever to be attended to. Truly, there are no precise rules to teach people how to walk in the streets, yet should you choose therefore to thrust your fist into a man's face as you went along, he would soon convince you that if there be no rules, there is not only such a thing as law, but a confoundedly plaguy deal of it too.

VI. Although not so intended, it is a far greater compliment than they deserve, to compare some of our recently-erected churches to barns. A barn is neither a disagreeable nor a ridiculous object. On the contrary, it is generally a pleasing, ofttimes a picturesque one, while of the other class of buildings not a few are the most anti-picturesque things conceivable; as architecture, vulgar, —not simple, but paltry, pert, and mean; without elegance, without solemnity, without soberness, without even the negative merit of unpretending homeliness. Dapper formality, and spruce insignificance are, for the most part, their distinguishing qualities, and awfully bad is the distinction they confer.

VII. Somehow or other there is a most obstinate prejudice in favour of admitting as much light as possible into rooms. To be sure, the upholsterer does his best to exclude half of it by his ample window draperies, without which most apartments would have a particularly dreary, chilling appearance; no shadow in any part of them, and, consequently, very little architectural effect, since to that shadow is almost indispensable. It is for this reason that vestibules, corridors, and such places, where the light is generally admitted far more sparingly, and frequently confined to nearly a single spot, are apart from anything else in their design, so much more pictorial than apartments, splendidly furnished perhaps, yet without any contrast of light or shade. To an artist's eye—and it should be so to an architect's—the one is as requisite as the other. Light there must be, but there should also be shadow: in other words, there should be just as much and no more light than effect demands. A few gleams of sunshine glancing into a room, give a far more brilliant and and delightful appearance than a blaze of it does. But then there will be dark corners; so much the better; there is no occasion to sit in them if you want to read; and as few people sit, like sentries in their boxes, all over a room at the same time, a person may place his chair in the light as well as out of it. A room which is not too strongly lighted, has also a great recommendation in its favour: it is, next to candlelight, the very best thing imaginable for a lady's looks and complexion. If you doubt it, ask Mrs. Candidus; and, however much we may differ on every other point, she agrees with me, heart and soul, on this.

ON THE GENERAL THEORY OF THE STEAM ENGINE.
No. 2.

BY ARISTIDES MORNAY, ESQ.

In resuming the investigation of the theory of the steam engine we feel it necessary, in the first place, to define clearly in what we consider that theory to consist. It is unquestionable that there are certain fixed laws, based on the principles of natural philosophy and mechanics, which determine and modify the development of the power of steam, and its action when applied through the medium of the steam engine to produce any required mechanical effect. The ensemble of these laws constitutes, of course, the general theory of the steam engine, and no theory which excludes any one of them can claim that title. Our present knowledge of the above mentioned sciences is sufficient to enable us to point out the various phenomena which take place during the working of the steam engine, and on which its action depends. These phenomena may be divided as follows:—

1. The generation of steam in the boiler and the circumstances

attending it, viz., its temperature, elastic force and density, and the caloric absorbed during the evaporating process.

2. The transmission of the steam from the boiler to the cylinder, and the changes of state which it undergoes during its transmission.

3. The pressure exerted by the steam against the surface of the piston at every instant of its stroke.

4. The nature and intensity of the resistance, which consists in general of the useful effect and the various resistances arising from the mechanical construction of the engine, including the resistance of the steam during its efflux from the cylinder.

We have already stated that M. De Pambour, in his proposed theory, entirely disregards the laws of the transmission of steam through pipes, which the following quotations from his pamphlet will prove. He says (page 44), "Let us, however, remark that, mathematically speaking, the pressure P′ of the steam in the cylinder can never be quite equal to P, which is the pressure in the boiler; because there exist between the boiler and the cylinder conduits through which the steam has to pass, and the passage of these conduits offers a certain resistance to the motion of the steam; whence results that there must exist on the side of the boiler a trifling surplus of pressure, equivalent to the overcoming of the obstacle. But as we have proved elsewhere, that with the usual dimensions of engines, this difference of pressure is not appreciable by the instruments used to measure the pressure in the boiler, the introduction of it into the calculations would render the formulæ more complicated without making them more exact. For this reason we neglect that difference here."

It should be observed that the above remarks are only intended to apply to the case of the minimum velocity of an engine, or its maximum of useful effect; in every other case the author not only neglects the excess of pressure necessary to force the steam through the conduits, but rejects altogether the supposition that any relation whatever can exist between the pressure in the boiler and that in the cylinder. In page 19 of his pamphlet he uses the following argument:—

"Finally, in looking over our experiments on locomotives, it will be seen that the same engine will sometimes draw a light load with a very high pressure in the boiler, and sometimes a heavy load with a very low pressure. It is then impossible to admit, as the ordinary calculation supposes, that any fixed ratio *whatever* has existed between the two pressures. Moreover, the effect just cited is easy to explain, for it depends simply on this, that in both cases the pressure in the boiler was superior to the resistance on the piston; and it needed no more, for the steam, generated at that pressure or at any other, satisfying merely that condition, to pass into the cylinder and assume the pressure of the resistance."

We alluded to this opinion in our first paper, when we also stated our acquiescence in that part which relates to the pressure in the cylinder, but showed at the same time, in a general manner, that the pressure in the boiler is not perfectly indifferent, the piston acting in some measure as a safety valve, and thus having a greater or less influence over the pressure in the boiler, according to its velocity.

With this exception, the influence of the above mentioned circumstances on the action of the steam engine is generally acknowledged. The two first depend on the nature and properties of steam, which should, therefore, be understood before we proceed any farther.

Steam is an invisible elastic fluid, similar in its physical properties to common air, or any other permanent gas.

It is well known that if water at 212 deg. fahr. be exposed to a higher temperature under a pressure of 30 inches of mercury, which is about the ordinary pressure of the atmosphere at the level of the sea, the caloric absorbed by the water will not raise its temperature, but will convert it gradually into steam of the same temperature, viz., 212 deg. The caloric thus absorbed without raising the temperature of the water is called *latent heat*, and its amount is estimated at about 1000 times as much as would increase the temperature of the same weight of water by one degree. The latent heat of steam at 212 deg., is, therefore, said to be equal to 1000 degrees; and from experiments made by Watt and Southern, it appears, that a certain quantity of water, at any given temperature, requires an addition of the same quantity of caloric to convert it into steam, whatever may be the temperature of the steam generated, so that the latent heat at any temperature t will be $1000+212-t$, and the sum of the sensible and latent heat will be a constant quantity, viz., 1212 degrees.

When steam is generated in a limited space, that space will shortly become saturated, provided there be a sufficiency of water present; and the quantity of water which a given space can contain in the form of steam varies with the temperature. When any given space is thus saturated with steam at a given temperature, the steam having then attained the greatest density which it can acquire at that temperature, is called *saturated steam*, which term originated in the idea that steam which is not in that state, if brought in contact with water at the same temperature as itself, will, with the assistance of heat, *dissolve* a certain portion of the water; which action will cease as soon as the steam has attained the maximum density corresponding to its temperature, whence it is then said to be saturated with water.

From what precedes, it follows that if a certain space were filled with saturated steam at a given temperature, and the space were suddenly extended without the admission of steam or water, or any gain or loss of heat by radiation, the increased space would be no less filled with saturated steam, but, of course, of less density, for there would be the same quantity of water in the gaseous state and the same quantity of caloric contained in it. The temperature of the steam would, therefore, fall to the degree corresponding to its diminished density.

The most important property of steam is its elastic force, being the source of all the power obtained in steam engines. We have mentioned that steam is generated at a temperature of 212 deg. under a pressure of 30 inches of mercury: this steam, therefore, exerts a pressure equivalent to the weight of 30 cubic inches of mercury, or about 14.7 lbs. on every square inch of surface with which it is in contact.

It would be extremely inconvenient if we only knew the elastic force of steam at those temperatures at which it had been determined by direct experiment, nor should we be able to judge of the accuracy of experiments made for that purpose without reference to some law, whether founded on reasoning, and coinciding in general with the best experiments, or deduced from the experiments alone, of which they serve to correct the irregularities, and so complete the series by interpolation. It is, however, very improbable that a formula constructed by the latter method should be applicable far beyond the limits of the experiments from which it was drawn.

Mr. Southern proposed the following formula, which he derived from the results of his own experiments:—

$$f=\frac{(t+51{\cdot}3)^{5{\cdot}13}}{87344000000}+{\cdot}1,$$

or by logarithms,

$$\log.\ (f-{\cdot}1)=5{\cdot}13\ \log.\ (t+51{\cdot}3)-10{\cdot}94123,$$

in which f is the elastic force of the steam in inches of mercury, and t its temperature by Fahrenheit's thermometer. By this formula we arrive at too low an elastic force, for all temperatures except 212 deg. and by Tredgold's formula,

$$f=\left(\frac{t+100}{177}\right)^6,$$

or

$$\log. f=6\ [\log.\ (t+100)-2\cdot24797],$$

we obtain too great an elastic force for all temperatures above 212 deg. and too little for those below it.

The following, which was adopted by M.M. Arago and Dulong, in their report to the Royal Academy of Sciences at Paris, agrees very well with their experiments between 4 and 24 atmospheres, above which their experiments were not carried; but gives too high a result from 212 to about 300 deg., and too low from 212 deg. downwards. This formula is

$$f=30\ [1\times{\cdot}003974\ (t-212)]5.$$

Dr. Ure remarked that the elastic force of steam at 210 deg., being 28.9 inches, that of steam at 220 deg. would be found by multiplying the former by 1·23; that the coefficient for the next interval of 10 degrees would be 1·22, and so on, diminishing the coefficient by ·01 for every ten degrees that the temperature is raised. The equation would thus be

$$f=28{\cdot}9\left[1{\cdot}23\times1{\cdot}22\times\ldots\ldots\times\left(1{\cdot}23-\frac{t-220}{1000}\right)\right]$$

This formula is in every case inconvenient, and is besides obviously inapplicable at high temperatures, for it gives the same elastic force at 440 deg. as at 450, and would show that above the latter temperature the elastic force diminishes with every rise of temperature, which is absurd.

From a comparison of Dr. Ure's experiments Mr. Ivory derived the following equation:—

$$\log.\ \frac{f}{30}={\cdot}0087466\ t-{\cdot}000015178\ t^2+{\cdot}000000024825\ t^3.$$

This is also rather difficult to apply, and becomes very erroneous at high temperatures.

The formulæ devised by MM. Arago and Dulong, and by Tredgold, are simple enough; but these, as well as all others hitherto proposed, contain some one or more constant coefficients, whose origin cannot be pointed out, for which reason no one of them can be regarded as representing the natural law. We therefore propose in the ensuing paper, to present a formula which may possibly be the expression of the law sought to be determined, as it contains no coefficient of which the origin cannot be traced.

IRISH RAILWAY DEBATE.

Parliamentary measures on that pernicious invention, the Irish railway job, commenced on the 1st of March, by Lord Morpeth moving the appropriation of £2,500,000 for this purpose. The subject was very appropriately preceded by some sparring relative to the partiality of the government. Mr. Lucas forcibly called attention to the injustice of the proceedings to the Central Irish Railway Company, and claimed on their part that they should be heard by counsel at the bar of the House against the recommendations of the jobbery. He pointed out the elastic rule by which they measured traffic, extending it in one instance, and reducing it to the narrowest limits in others. Mr. Hodgson Hinde called attention to the report of the committee on railways, and the proceedings of government on the Morecambe Bay and the Scotch railways, when they refused even to appoint a commissioner to decide on their relative merits. Mr. Hinde observed there was certainly one species of justice toward this country, and another species of justice to Ireland. Colonel Perceval called the attention of the House to the notorious change of the clause with regard to joint stock companies on the renewal of the commission. Lord John Russell and Viscount Morpeth both replied to this charge, that the ministry were unconscious that the change was made, and thus afforded a glorious proof of the system of ministerial responsibility.

The business of the evening was then commenced in earnest by Lord Morpeth, and never did ministerial hack have a more unfortunate cause to plead, or pronounce sophistries so palpably diaphanous. He boasted of the unanimity with which all parties in Ireland had hailed this measure, and called upon the House to grant money to those who proved their worthiness of it by their readiness to receive it. Henceforth a gift is not to be determined by the willingness of the donor, but by the openhandedness of the recipient! The noble viscount gave a fearful state of the poverty of Ireland compared to England, and pointed out the solitary railway in one, and the sixty millions' worth in the other; that Ireland had only 400 miles of water navigation, and England 4000; and upon this he attempted to base a claim for the deficiency being supplied at the national expense. If this system be indeed adopted, it is one to which no limit can be assigned but the entire destruction of the resources of the empire, and establishing Ireland as a pet farm of the imperial government. We begin by making all the railways, and it will be but justice to make up the deficiency of canals, and what will follow next heaven knows; but there can be little doubt that, were this system once pursued, there would be no falling back in the *merits* of Ireland, and that we should be saddled with a perpetual premium for their poverty. If such claims be but admitted, it must be recollected that England herself has millions of acres of waste land, of which the interests of a pauperised population imperatively demand the cultivation, and that Scotland has abundance of barren hills and glens, which would look more beautiful with forests raised from English gold. The next claim is, that large sums of money have been spent on the Caledonian and Rideau canals, and with a want of merit surpassing that of Irish misery, the ministry dare to appeal to measures which are the most convincing proofs of their incapacity and extravagance. Belgium was again brought forward, and the apparent success of the government plans was triumphantly relied upon; but it would be a silly act to be allured by even the most attractive examples to place in the hands of government the controul over the whole traffic of the country. By the poor law, the administration hold the working population of the country at their command, by the police they keep them in coercion, and by monopolising the means of transport, they would then obtain an equal power over the whole traffic of the country, and all the resources of the farmer and the manufacturer. Instead of a government suspension of bank payments, let us have another William Pitt stop at once the whole communication of the country, and we shall then see how the industrial classes will be paralysed by the weapons they themselves have forged. Lord Morpeth most strongly acknowledged the resources of Ireland, and the manner in which they repaid the exertions of public enterprise: and yet, with manifest inconsistency, he subsequently endeavoured to depreciate them; the ancient satyr would have felt horrified at this blowing hot and cold. The unfortunate lord favoured the whole House with a recitation of the sentiments of the open-mouthed candidates for the 'tin,' passed at their public meetings, and thus adopted them as his own. One of these sets of suitors 'in forma pauperis' urges that—

"Capital would be obtained at a much lower rate of interest, and the enormous law costs, and those consequent upon parliamentary investigations, almost entirely saved; while the professional assistance to be obtained in the several public departments would be calculated materially to lessen the general expense."

This is, verily, Tom Thumb's making giants and then killing them; and our Government Glumdalca first oppresses the railway companies by the standing orders, and then urges against them the misery produced—like as we enslaved the negroes, and then degraded them for the results of our oppression. The noble viscount did, however, acknowledge that the country was immensely indebted to the energy (!) the skill (!!) and the enterprise (!!!) which those companies (the English) had displayed.

Still farther "going the whole hog" in this stream of inconsistency, it is not wonderful if the unlucky animal should give a few digs against its own throat. Attacking the English railways (*quod et eundem est* as the future Irish jobbery), he says:—

"It is now beginning to be ascertained, that great as are the advantages which have resulted from these undertakings, there are to be found among them some of those *abuses* and *imperfections* which MONOPOLY and IRRESPONSIBILITY seem, as it were, by the law of nature, to bring about in time!!!"

Taking advantage of the experience gained by the failures of the early English attempts, the self-denying minister is not contented with employing the results of their labours, but he blames them for the very imperfections which by their exertions he is enabled to avoid. We should like to know if, as a part of the ex-Irish Secretary's advocacy of Belgian principles, he is prepared to carry out their system in all its admirable details, particularly that part on which he dwells, of the *non-interference of private interests*, which it is well known no foreign government ever allows to *interfere* with its object, as the noble lord might learn from some of the proprietors on the Belgian lines. Most pathetically did Lord Morpeth recite the expenditure to which the English railways had been subjected, and never did crocodile so bemoan its victims:—

One of the great items of expense regarding railways was that of conducting them through Parliament. That expense alone, even in very long lines, exceeded 1,000*l.* per mile. (Hear, hear.) The parliamentary expenses of the London and Birmingham line were 72,868*l.*: of the Great Western, 88,710*l.*; of the London and Southampton, 39,000*l.*; of the Midland Counties' Railroad, 28,000*l.*, which (with some others mentioned by the noble lord) amounted to 2½ per cent. on the gross expenditure. Another great expense was the enormous amount of compensation given to individuals possessing large parliamentary interest. The statement which had been made by the Member for Leicester touched upon that point. He stated that cases were known in which individuals possessing large parliamentary interest received ten times the amount of compensation that did other individuals in precisely the same circumstances. In one case, which had been made the subject of trial in the Court of Chancery, it appeared that a nobleman had withdrawn his opposition to the bill in consideration of receiving 100,000*l.* for injury done to his estate.

And yet for all this, the jobbery advocate talks of the expense of lines executed by private individuals, and talks as if the same results would be produced in Ireland. He can best tell how far the Irish companies will be subjected to the Parliamentary screw; but as to the value of land, or that of wages, there is an immense difference in favour of Ireland. He speaks with great unction of the *generous* gifts of land by Irish proprietors; but, if the noble lord be reported correctly, the same thing has been done in England, where in one county donations were made to the extent of 50,000*l.* The noble lord could not, of course, omit that beautiful argument about private companies screwing the profits to the highest pitch, and the devoted conduct of Government, which never asks more than the lowest farthing. He forgot, however, to furnish any illustrations of this; but we are happy to supply this deficiency by alluding to that admirable institution, the Post Office, which does not indeed take the lowest farthing, but, by a beautiful metonymy, realises the words of Scripture as to the *last farthing*. Lord Morpeth cited one fact with regard to Belgium, which might impress upon many of our companies the policy of a reduction in their fares:—

The returns from Belgium showed that in 1837 a population of 232,000 made five trips per annum. In England there was an increase over the travelling by the former modes of conveyance of 218 per cent. In Belgium, previous to the formation of the railway, 80,000 persons passed on the old road, paying 4s. and 2s. 6d. With a change to 2s. 6d., and 1s., these being the railway prices, the travellers amounted in the year 1837 to 781,000, which was an advance of 876 per cent., being an increase 9½ times greater than the former amount of travelling.

After having made a great deal of palaver about those wicked dogs, the Joint Stock Companies, choosing the best lines for themselves, in the first instance, and leaving others only the bones to pick, and eulogising the conduct of the government in taking fat and lean together; lo! we find at the last moment, that the teetotals do not like bone-picking any more than any one else, and that their measures in the first instance are to be restricted to the grand trunk lines! The good-natured lord very candidly admits that the line now proposed to be adopted is of sufficient magnitude to test the value of the intended experiment. Yes! no question of that, for choosing one of the best lines, the government will appeal to its productive results prepared to spend money, and the non-paying lines also. With equal generosity and with all forgetfulness of his former story, that "Jack Sprat could eat no fat," he now very kindly expresses his intention of leaving a portion for private enterprise. A work of true charity, stealing an ox and giving the hide among the poor! As an encouragement to the English farmer, and an inducement to the corn law supporters, he informs them that the most striking benefit would be, the agricultural produce coming from Tipperary, Cork, Limerick, Clare and Waterford. A very striking feature truly, and one which may well prevail upon John Bull to disburse the money for the procession, although to vulgar minds it might appear more equitable, that if such landholders are so fond of giving locomotive powers to their cattle, that they might do it at their own expense. The principal inducement to commence the first line, the ridiculous line from Dublin to Cork, is that there are neither canals nor navigable rivers in that part of the country! Perhaps the acumen of another twenty-thousand-pound commission might enable the noble lord to find a still more eligible site, one in which there would not be even any people at all! As a bonus to the Liverpool people, Lord Morpeth informs them, that his plan will open a communication between the Lancashire manufacturing district, and the south of Ireland; but in the dregs we find that, as Cork is much resorted to by vessels trading to America, it will be in effect facilitating the communication with the United States. Cold comfort this for the Liverpuddlians, and it is very doubtful whether this piping will have any effect in conciliating their sweet voices. We should like to know, however, why Cork is to be made an American port at the national expense, when no interference was exercised in the recent instance of Atlantic steam navigation, which by the means of private enterprise is so much promoting the American trade of Bristol, and so competing with London and Liverpool. We hear nothing either in these plans about any benefit which is to accrue to the South of England by these splendid plans, or what possible inducement can be urged on them for their promotion. Surely the Munster people might be satisfied with their agricultural trade through Bristol, without forcing us to pay through the nose for giving them an outlet to the north. The noble lord vaunts the disinterestedness of ministry, and their non-interference with the patronage of the Irish Board of Works. We shall leave others to decide how this may be, but it is a strong argument against the nonsense of superior responsibility. The various ministerial arrangements would have the effect, he trusted, of preventing a profuse expenditure of public money. We should be very willing to believe this, but "wolf" has been cried so often, and we have so many instances of their extravagance before us, that we regard them with the same eye that we do a prodigal son, applying to his parents for another supply of money. It will be a very great consolation to those companies, the merits of which have been disparaged by the job-ation, that Lord Morpeth believes that the operators have purposely underrated the amount of profits. A silver plate on their coffins, or a statue to a poet dead of starvation, are just about as gratifying as this testimony of the resources of Ireland, which have been ruined in the eyes of all capitalists. The noble lord concluded by developing a plan, which he had very probably received like the armour of Achilles from his goddess mother, or perhaps from Queen Mab as a specimen of the manufacture of Messrs. Cobweb, Peasblossom, and Mustardseed. England is not to advance one farthing, she is only to accept the bills, and the security is most eligible, for if the drawers, *i. e.* the railways, do not pay, the amount is to be reimbursed by the Irish themselves. It is needless to say, that this most flimsy contrivance will only ensnare people who like to be robbed with their eyes open, for there is no great genuis required to foresee that the railway grants must go the way of the tithe million, and so many other sums which wander like ghosts on the Stygian shore, far from the land to which they owe allegiance. We do not think it necessary to state the impression which this speech made upon us, for in truth it was none at all, and we rather think that our comments will make the greater impression of the two.

Mr. Redington acknowledged that the committee were very candid in their report as to his part of Ireland, for in page 45 they state, that with respect to railways westward they had not thought it necessary, under existing circumstances, to make any enquiry; being doubtless engaged in the consideration of their jobs elsewhere, and not being desirous of executing the purpose for which they were alleged to be appointed, viz., to examine and decide upon a general system of railways.

Sir Robert Peel combated the measures of the ministry with his natural talent, and the aptitude he had acquired from his commercial connections. He pointedly remarked the scramble among the approved candidates as to who should have the first finger in the pie, and urged that if begun, the plan could only end in an extravagant expenditure of English money. The principle, he said, was neither more nor less than to take the capital of individuals in different parts of the country, for the purpose of sanctioning one particular scheme. He asked why, if poverty were to be admitted as a claim, Wales should not put in her demand, because her customs returns were even smaller than those of Ireland? The real question, said he, is

Whether or not it would be for the benefit of the country to teach it to rely on the intervention and support of the government, or leave competition free, and allow Ireland to follow the example of her neighbour, trusting for the same prosperity, and the same facilities of communication, to precisely the same means which had insured them in England. He found in this report ample proofs that if individuals in Ireland were enterprising and intelligent they would succeed. What said the report with respect to a single individual having every difficulty to contend with? In order to convince him that it would be proper for government to interfere in a case of this kind, a report was produced having for its object to show how enormously profits and prosperity increased by opening railway communications. That was one object of the report; and it did prove that position most conclusively. It took the case apparently the most surrounded with difficulties, the least tempting speculation any one could well imagine another individual to enter into; it took the case of a native of Milan with very little capital, who determined to settle in the county town of Tipperary, undeterred by all the accounts of violence, and all the prejudice which might operate against him—a foreigner, single, unsupported, ignorant of the language, bringing intelligence and industry to individual enterprise, and acting by that love of profit which actuated all speculators; and what was the result? "With a capital little exceeding the expense of the outfit, he commenced," says the report, "running a car between Clonmel and Cahir,"—then in a disturbed state. "Fortune, or rather the due reward of industry and integrity, favoured his first efforts, and he soon began to increase the number of his cars, and has now 94 public carriages in constant work, and the distances traversed by them exceed 3,000 miles per day." "These results," said the report, "are the more striking and instructive, as having been accomplished in a district which has been long represented as the focus of unreclaimed violence and barbarism, where neither life nor property can be deemed secure."

As to the absurd claim of deficiency of public works, Sir Robert justly observes, that they might as well call for the establishment of cotton factories in Ireland, because England has a great many, and Ireland none.

It really was a great insult to the people of Ireland to suppose that they were not capable of appreciating the benefits of railroads, and that it was necessary for a public department to introcuce among them all the improvements which had taken place in that mode of communication. He knew how plausible it appeared at first sight to advance English credit in support of such an undertaking; but, although he took no objection in point of expense, his firm belief was, that the moment government interposed and supplied its credit, it must inevitably disparage native intelligence, industry, and enterprise, besides being a most unfair interference with the capital already in the field.

The introduction of government capital, he said, was an unfair competition, which no private individual could sustain, although he might be ready to abide the consequences of fair contest with individuals or public companies. Sir Robert calls on the landholders of Ireland themselves to execute these lines, if they are so convinced of their advantages, and boldly urged the moral bearing of the question.

When they shall have done that, the moral improvement produced upon the people of Ireland, from its landowners relying upon their exertions, will exceed tenfold that which would be produced by a Government Board with enormous patronage, interposing in such a concern, and proceeding on the old assumption, so much deprecated on the other side of the house, that the inhabitants of Ireland are an inferior people. He called upon the government consider well what they were about to do. They were reversing all the principles on which they ordinarily relied. They asked the house to grant municipal corporations to Ireland, on the ground that it would enable its inhabitants to superintend and manage their own concerns, and yet, in the present instance, they called upon the members for, and indeed upon the whole people of Ireland, to consent to their own disqualification in so important a matter as the formation, construction, and supervision of their railroads, and to abstain from doing those things for themselves, which had been done in the poorer districts of Great Britain.

The political consequences, and the manner in which the working of this plan might be used as a cat's-paw, are shown with equal force.

They would convince him that this measure would be for the permanent improvement of Ireland he would at once withdraw his opposition to it; but if the employment which it was to give to the people of Ireland was only to be temporary, and was merely meant as an adjunct to aid the operation of the new system of poor laws recently introduced into that country, then he was convinced that even if it did not work immediate harm, it would not work any permanent good. The employment, which arose from the natural course of events, and from the spontaneous application of capital, would confer more permanent advantage upon Ireland than the application of countless millions, which would only give employment for a time to the people of Ireland.

Mr. Spring Rice followed in a lame-duck speech, in which he called upon the House to persevere in the erroneous system, which, for the last forty years, they had adopted; and because they had hitherto spent so much money on Ireland, be called upon them to disburse more. He would have done better to have shown what had been the industrial and moral results of this system, to have pointed out that while Ireland had been deprived of its energy, and induced to depend upon the government leaning-stock, that she has only 400 miles of canals instead of 2,000, and that she is in arrear in all public works. The right honourable gentleman very wisely confessed that he did not wish to defend the Caledonian and Rideau canals, which his colleague had so unnecessarily conjured up before the presence of the house, as if to call witnesses from the dead to expose the incapacity of the government and the inanity of their strongest promises. With regard to temporary employment, he observed, that he believed

That temporary employment of such a character would be productive of more evil than good to Ireland. He believed that the temporary employment which the formation of the Caledonian canal created in Scotland had not done any good to that country. He had been informed that it had rather introduced into Scotland a number of Irish labourers, than given any additional employment to Scottish labourers.

Mr. O'Connell expressed his sentiments in a rambling speech, rather at variance with his original sentiments. We can, however, in consideration of his anxiety to pocket so much money for Ireland, forgive his inconsistency, but that does not induce us to place any confidence in his opinions. Mr. O'Connell is not Aristides, or he might acknowledge that, although a measure may be very advantageous to his country, it may be very unjust. He however enforced the importance of private enterprise, by pointing out that, in the case of Mr. Bianconi, he had received no support from government. Mr. O'Connell, of course, urged the example of Belgium and other states, and proved his knowledge of the subject by asserting that *there is not a freer constitution in existence than that of Belgium!* He forgot, however, to allude to one feature of government administration of public works; that in time of war governments become incapacitated, and augment, by all means, the revenues derived from these sources, while private enterprise has been so deadened, that, like poor Smike, it can never get out of its leading-strings.

Mr. H. Grattan made a noble exhibition of Irish patriotism; he said that—

They did not wish in Ireland for English money; all they said was, "Give us back some part of the sums drained from us by absenteeism." He could prove, by documents which he held in his hand, that the amount spent out of Ireland in this way was not less than 273,000*l.* per annum. This was what the Irish wished for; but if they could get that, they would be content with the assistance of government in the undertakings now under discussion.

Thus, admitting this calculation of the loss by absenteeism to be correct, and making no allowance for its annual diminution, nor for the difference made up in England by agricultural produce exported, Mr. Grattan very kindly, by way of instalment, proposes to take ten years' annuity in advance, or, instead of 273,000*l.* per year, 2,500,000*l.* As a part of the compensation question, this gentleman consistently concludes by saying that—

It was indispensable to have English capital. The English capitalist would lose nothing by the outlay; while that outlay, at the same time, would repay the Irish for some part of what they had suffered.

Mr. Lucas called upon Government to come to some decision as to the two western lines, which, however despised, were ready to carry out their plans with their own money. This gentleman proposed that if government were determined upon the general job system, that they should require that one half of the outlay should be disbursed by the landowners of the line, and the government expenditure thus reduced. Mr. Lucas lauded the arrangements of the French government:—

France also was in advance of us in this field, having found means of obtaining security for the public against those effects of monopoly which so many here complained of. In every act (if he might so speak) which passed the Chambers, he was told there was a provision inserted for imposing upon the the company a *maximum* of fares—that was to say, they were forbidden to exceed in their charges from 20 to 25 per cent. over and above a remunerating price. For instance, if 7*s.* would barely defray the expenses of carriage, they were unable to ask more than about 9*s.* for their fare.

This certainly appears at first sight a useful and economical provision; but nothing in its operations can be more injurious, for the maximum adopted in France is so low that while few undertakings can keep up to it, even those which do, offer no inducement for the further prosecution of such designs. While in England, however the public may appear at first to suffer, the large dividends obtained act as a stimulus even for the formation of non-productive undertakings, and this is the true cause of the great number of canals and other works in England, and their paucity elsewhere. Mr. Lucas might also have told the House that the French Chambers rejected last year the principle of government administration, and that so far from this principle having made progress, it received a check.

Mr. Wyse wished to know why the line proposed should stop at Clonmel and go into Waterford?

Mr. W. Roche inferred that the expenditure in Ireland, in the way of improvements, had met with most abundant returns, and he relied upon the increase of traffic which must result from the promotion of public works. Indeed the jobationists, in their ridiculous and variable calculations of traffic too often forget its certain increase, but treat it like ore raised from the mine, as if it were independent of the gold which is to be extracted from it.

Mr. Joseph Hume delivered a quantity of his usual twaddle, in which he appeared very much in the position of a tame tiger, which is expected to exhibit its ferocious propensities, and is yet kept in order by a sop in the pan. He vibrated like a pendulum, between his old notions and his anomalous Irish position, and a most strange harlequinade was the result. Among other things he confessed that the house was for the first time called upon to undertake a general work for a mercantile speculation, and it behoved them to ascertain well to what extent the plan was to be carried. Among the useful matter which could be extracted from his soporification, he assured the house from his personal experience that Belgium was no example to this country, for instead of government administration being admitted as a fixed principle it was only adopted on an emergency, and that most of the state works in America were executed with English capital, and that consequently it was quite different in this country which supplied the money to itself. He believed also that England had hitherto been burthened by Ireland, and not as Mr. Grattan said, was indebted to her.

Sir Robert Inglis said:—

As one who took also into consideration the interests of England, he should be glad to learn from the Hon. Member for Dublin, if he should succeed in obtaining a repeal of the union between the two countries, what security would be given for the repayment of the proposed advance. (Hear, hear, and a laugh.) If there should be distinct legislatures, it was natural to expect that the finance department of the two countries would be separate. In that case, he should like to know what security this country would have for the repayment of the money, when the new Parliament should be sitting in College-green!

To this Mr. O'Connell replied that he would give him his own.

Sir Edward Knatchbull observed, that he very much feared that as to the security offered by the learned Member for Dublin, that when the matter came to be considered in Ireland, some flaw would be found by which the engagement would be considered void, and, as he had said, not one penny of it would be repaid.

Mr. Slaney showed the advantages of Ireland as to the price of labour, by stating that men were glad to get employment for 8*d.*, 7*d.*, and even as low as 5*d.* per day.

Sir George Strickland deprecated the government interference in railways; and said that if they did this in imitation of France and Belgium, he did not see why they might not be called upon to imitate them in other respects, by setting up monopolies in particular trades. All government speculations in public works had been failures; they had proved so in roads and canals in Scotland and Canada, and would equally fail in Ireland.

Lord Sandon remarked, that while agricultural produce was depended upon as traffic in Ireland, experience had proved a contrary result in England. There were many works of great public utility which could be carried on in Ireland, by the aid of government, with much more advantage to the country than railroads. Some few years ago it was proposed to grant a sum of from 150,000*l.* to 300,000*l.* a year for opening the resources of ten counties of Ireland, by improving the navigation of the Shannon, but the Chancellor of the Exchequer threw every obstacle in the way of the grant, and now he supported the present very large sum without any thing like the same prospect that its application would be successful. If government wished to improve the resources of Ireland, let them extend its water communications—let them give their aid in opening the navigation of the Suire, the Barrow, and the Shannon, and he was sure that the house would not be backward in affording the necessary pecuniary aid; but he did not think that it ought to support an experiment arising out of the mania for railroads. Unless the present plan was part of a whole scheme for carrying on railroads by government aid in all the British islands, he thought they ought not to take this step without due consideration. If they carried this, he did not see how they could resist the claims of Scotland for aid in similar works.

A discussion afterwards ensued as to the conveyance of goods on railways, in which Mr. Ashton Yates denied the correctness of Lord Sandon's views, but most unjustly, for it is a matter of notoriety to all connected with railways.

After a parting address from Lord Morpeth the discussion ended by the House dividing on the motion, which was carried by 144 to 100, or by a majority of 44; but it is considered that the success of this experiment is not such as to induce the ministers to persevere. All farther measures are now delayed until after Easter.

We need scarcely say that nothing has occurred in this debate to alter the views that we have maintained throughout the discussion of this question, in which for a long while the *Times* and ourselves were the only parties engaged in opposing its injurious consequences. Every thing has tended to confirm us in the impression that it is as unwise as it is uncalled for. This is not a question of money, but of principle; not one of so many millions, but of the moral prosperity of the empire; and while we may regret any support which we may give to this innovation. Ireland, however apparently benefited, cannot fail to be injured by that genuine deprivation of resources, the incapability of availing herself of them. Indeed, if we wished not to treat Ireland as an equal, but as a subsidiary province, we could not do better than to imitate the old Roman policy of enervating those whom we wish to keep in chains. *Quem Deus vult perdere prius dementat.* As regards its financial bearings, experience has but too well impressed upon us the frailty of the proposed security, and the much more probable contingency of having to disburse the money from our own sources. Ireland can urge no moral claim to this participation in the general revenues, for instead of bearing an equal degree of taxation, she is free from many of the burdens to which England is subjected for the advantage of the sister country; and we cannot but impress both upon Irish and English the impolicy of a measure which, both in its moral and financial bearings, is equally unsupported by sound reasoning or compensating advantages.

MODELS AND DESIGNS FOR THE NELSON MONUMENT.

If not particularly satisfactory in itself, this competition has been attended with one exceedingly important result, one that is likely to prove an effectual step towards a better and more trustworthy mode of proceeding in future upon all similar occasions. The designs for the Houses of Parliament were exhibited subsequently to the final decision on the part of the commissioners; those for the Nelson Monument after the premiums had been awarded by the sub-committee—but, fortunately, in time to admit of their judgment being reversed, when, instead of ratifying it, the public voice protested against it. So far there is very great room for congratulating ourselves on the precedent thus furnished, and which we may reasonably anticipate will henceforth be followed, with this improvement upon it, namely, that the public will be admitted to view the models and drawings before any premiums be awarded or any selection made. Gladly, therefore, do we hail what has been done in regard to the present competition as a most favourable augury. If, in the first instance, no very great judgment was shown, there has been no unfairness, no obstinacy, no selfish determination to abide by the choice originally made; or if such determination existed anywhere, it has been quashed by a counter-determination emanating from some higher and more honourable quarter. But for the circumstance of the designs being exhibited, and public opinion attended to, the whole business would have been settled, as hitherto, behind the curtain, and almost the first positive information we should have had in regard to the matter would have been the preparations for carrying into effect the design to which the first premium has been awarded.

In regard to the premiums which have been bestowed, we will say nothing, except that that part of the business holds out a most wholesome caution against any similar precipitancy for the time to come; because it is in itself hardly worth a moment's consideration in comparison with the most important point—the laudable resolution evinced to obtain, if possible, such design as shall be in every respect creditable to the arts in this country.

Sincerely do we congratulate professional men, both sculptors and architects, on what has now for the first time occurred. It is true they have been turned back like schoolboys, and sent to get their tasks better; and so far it must be allowed to be somewhat mortifying to the actual competitors. Still we congratulate the profession as a body; because that very circumstance affords proof how much importance the public attach to the matter, whereas the time has been when the public would not have troubled their heads at all about it. Farther we most heartily congratulate them, because should the system thus begun be—as we devoutly hope it will—persevered in, there is now an end to all favouritism, all jobbery and jobbing. There will be fair play for talent, because when manifested it must be recognised—at all events, it cannot possibly be thrust into the background by any manœuvring; to say nothing of the responsibility which those with whom selection rests, would find attach to them. Hitherto such responsibility has not existed; we may in many cases suspect that there has been either a very great want of judgment, or else very undue partiality, unless we choose to suppose that, unworthy as it may be, the design adopted was nevertheless the best among those offered for selection. Could we behold all the designs sent in for various buildings, and compare them with the buildings respectively executed, we should, no doubt, in many instances be filled with utter astonishment. For all general competitions the invariable rule ought to be a public exhibition beforehand, whence a certain degree of responsibility on the part of the judges would follow as a matter of course; while for limited competitions, that is, where a certain number of architects are applied to for designs, each competitor should be separately examined before a committee, and called upon to explain thoroughly all his drawings, and his ideas of the subject, and also to answer whatever questions may be put to him.

We have spoken somewhat more at length than we intended, upon what, after all, does not belong to our subject as that of the exhibition itself. In considering this we shall be comparatively brief, because, even were the whole matter not now in abeyance, and were it not therefore likely that many of the designs will come under our notice again in an amended form, we are not prepared to give our readers what we should consider a full and accurate review of the majority of subjects after repeated examinations of them. We therefore profess to do little more than record our impressions at one or two visits, singling out for mention a few of the *notabilities*. Now, although we do not mean to deny that several of the models and designs exhibit great merit, many good ideas, and much beauty, in parts, we must be allowed to acknowledge there is hardly a single one we should wish to see adopted without some further modification. Among the models there are some very beautiful, considered as models, and as these consist chiefly of sculpture, they would be novelties, for at present we have no public embellishments of the kind, except single statues, and those for the most part on a very moderate scale. On that account we should be inclined to give the preference to something of the kind; more especially as it would be least likely to interfere with the surrounding buildings. As far, however, as regards adaptation to the particular site, we are not furnished with any means of judging what the effect would be except in one or two instances, where a perspective view accompanies the model, showing what would be its appearance when executed on the proposed scale, and beheld with the actual architectural back-ground there would be to it. Now, we think it ought to have been made a condition that every model should be accompanied by such view, both because models taken by themselves, except of mere pieces of statuary, are apt to be fallacious, and because they overpower drawings, and render it exceedingly difficult to judge fairly between two designs shown by such very opposite modes of representation. It was, besides, a very great error not to establish one uniform scale for the designs—perhaps one for the drawings and another for the models; had which been done much inconvenience might have been obviated. It has been suggested in some newspaper—if we mistake not, the "Atlas"—that with regard to the models it would have been advisable to have had them on the same scale, and then placed successively for examination in the centre of a model, showing the fronts of the buildings around Trafalgar-square. This would certainly have afforded a most satisfactory test of their effect, and their adaptation to the site itself; while it would, we suspect, in more than one instance have saved the competitors considerable expense, incurred by the models being on a considerably larger scale than would then have been admissible. And in regard to the expense which the competitors have been at, we will here remark that we do not see what that has at all to do with the matter. Some one has computed that the gross amount cannot be much less than 7,500 guineas. Be it so—what then? each individual contributes towards it not one farthing more either of money or time than he would have done had it been only a tenth part of that sum. Therefore, as an individual, he has infinitely less reason to complain than if he had fewer associates in his misfortune. Every one knows beforehand that but one design can be actually adopted, and surely it cannot be one whit more galling to be one of the hundred and forty-nine out of a hundred and fifty, than one of the nine out of ten. Talking of the aggregate amount, the "sum TOTTLE of the whole," as Hume says, is all stuff. Besides, there are not a few designs which we think could have cost nothing at all, except a shilling's worth of paper and couple of hours' of time.

Among the models, that by Mr. T. Woodington, No. 8, struck us as recommending itself by its graceful simplicity, and the pleasing contrast in composition produced by the four recumbent figures upon lofty socles, projecting out diagonally from the central mass or pedestal. Executed upon a commanding scale, this design would form an imposing object in the centre of the square, without at all interfering with the surrounding buildings. Nevertheless we conceive it would have been greatly better, would have been more appropriately characteristic, and possessed withal greater novelty of form, had there been only three figures, emblematical of the three grand victories of the Nile, Copenhagen, and Trafalgar, forming the three points of a triangular plan below, the principal one of which, or that allusive to the battle of Trafalgar, should be facing towards Charing-cross; which disposition would accord exceedingly well with the oblique line of the houses, right and left, forming the embouchure into Parliament-street. To say the truth, we were not a little surprised at finding that in not one of the designs—not one, at least, which we observed—has the idea been adopted of indicating the three memorable victories, by a corresponding number of points in the composition; although it might have been accomplished various ways, and apart from its significancy, with exceedingly good effect.

On the subject of Mr. Baily's model we need not say much, as we agree in the opinion generally expressed as to its merit as a graceful assemblage of sculpture, save to remark that, though abstractedly considered, it is exceedingly tasteful, it seems deficient in energy of meaning. A similar remark applies to that by Pitts, which, while it exhibits much talent and mastery as a piece of sculpture, is too enigmatical for the intended purpose. No. 38, by Westmacott and Nixon, has great merit as it is, yet would be improved by being somewhat simplified. And in No. 40, by C. H. Smith, there is considerable cleverness and originality; yet this, too, would, in our opinion, be improved by hollowing out the blank arches on three sides of the basement, so as to convert them into recesses for the figures, which are now merely placed before them. Very likely this would require some further modification of the whole of the lower part, so as to obtain sufficient depth for the purpose, yet very little difficulty, we conceive, would attend such alteration. Mr. E. J. Papworth's design, No. 36, a column on a perforated rock, within which are figures, would, on the contrary, have been better, had only the sides of the rocks been hollowed out.

We do not profess to understand Mr. Patrick Park's model, nor have we seen his explanation of it, wherein, we are informed, he speaks at length of the "principles" which directed him in designing. Very possibly it may be replete with meaning, or what is intended as such, but it is certainly far too recondite; and therefore, as a design, it struck us chiefly as a strange array of figures posted about, which jumbled appearance is further increased by a number of huge lions walking in a circle round the whole. Whatever ingenuity there may be in the ideas intended to be thus expressed, the result is any thing but a happy one, which remark applies to several other designs wherein parts or ornaments, intended to have a symbolic meaning, produce more or less awkwardness of form. However appropriate the ideas attempted to be conveyed may be in themselves, they had better in all such cases be abandoned, if they cannot be reconciled with beauty of form—with either picturesque or architectural effect. It is poor satisfaction, when we look upon incongruous whims, to be told that they are intended to indicate such or such qualities and circumstances, especially as, after all, merit of that kind, unless accompanied with refined artistical feeling, is of too fantastical a kind. Most unquestionably the mind ought to be satisfied, but at the same time the eye ought to be satisfied equally well—certainly not offended.

While considered as a model, that by Salvin and Smith, is one very striking in point of size, and exceedingly beautiful in execution; it is very far from recommending itself as a design, being an ornamental structure in an exceedingly florid but impure style of architecture, and, therefore, on that account alone would be highly exceptionable for such a situation as the centre of Trafalgar-square, where it would be altogether out of keeping with the other buildings, and would cause them to appear more naked than they do at present, while they in turn would occasion it to look whimsically grotesque in taste. The same observation applies even still far more forcibly to the design, No. 44, with the motto, "England expects every man will do his duty." In this drawing extraordinary diligence has been employed in producing an assemblage of all the most licentious caprices of the Italian school, at its most corrupt period. It is an Italianized pagoda, bedizened out from top to bottom with as much architectural finery—such as it is—as could be crammed into it. It is the very quintessence of that gorgeously bad taste which is now gone out of vogue, even in Italy itself; and as a monument to Nelson, Gibbs's church in the Strand, would be about as appropriate.

There are others who have proposed buildings, and not merely ornamental structures, but such as, if executed, would totally change the character of Trafalgar-square. Among the rest is Mr. Haydon, whose design—forming a most singular contrast to the one we have just been speaking of—is for a plain Grecian-Doric building with a portico, and forming, within, a large hall, divided into two separate compartments by columns, each of which would be lighted from above, and decorated not with fresco paintings on the walls, but large historical pictures in frames, commemorating different events in the life of the hero. Whatever else may be thought of such ideas, it is characteristic enough:—"Vous etes orfevre, M. Josse, et votre conseil sent son homme qui a envie de se defaire de son machandise." What may be the proposed dimensions we are unable to state; yet either it would be an insignificant little edifice planted by itself in the centre of the square, or if as lofty as the buildings around it, so large as to block up the square, and cut off the view of St. Martin's church, and the National Gallery, from Cockspur-street and Spring Gardens.

No. 89 is another whimsical piece of absurdity, the author of which, however, has had the discretion not to reveal his name; which is the only sensible thing he has done, for the design itself is neither more nor less than a square campanile in the Italian style, divided into several stories; but whether a statue of Nelson is imprisoned in any part of the inside, we have not the means of saying.

There are not a few other extravagances—things without the slightest mark or likelihood, and which are only curious as displaying poverty of invention, sterility of imagination, and exquisitely bad taste; things, in short, at which the sub-committee must have stood aghast; although their oddness must, at the same time, have extorted from them cordial smiles, though not of approbation. Not so No. 116, that being, at all events, no laughing matter, for a piece of more egregious dulness than that strange house-front design does not present itself in the whole exhibition.

Well, of course the authors of all these deplorable performances will now retire; and many, we have no doubt, will now be able greatly to improve their designs, should not entirely fresh ideas occur to them. One of the best of those in which a column forms the principal, if not sole feature, is No. 102, by Marsh Nelson, the perspective drawings accompanying which are remarkably clever. This design proposes that the whole of Trafalgar-square should be raised to a uniform level, forming a balustrade terrace, with a spacious flight of steps towards Charing-cross. Still we are of opinion the better mode would be to obtain a level by sinking the ground on the north side, instead of raising it on the south, so as to convert the road in front of the National Gallery into a terrace, elevated above the area of the square, by which means that building would acquire apparent loftiness, at least of situation, while the view of the square would not be obstructed, as by the ground being raised it would be, from Charing-cross. If we mistake not, this is proposed by Mr. Goldicutt's design, which is so far worthy of being adopted; though, as for the design itself, which is for a huge globe, with Nelson standing on the top of it, we cannot say that it is at all to our taste. Among the more eligible designs is No. 36 by T. H. Nixon, a bold, sepia drawing—hung rather too high—exhibiting a statue and richly-ornamented pedestal. There is also much to admire in No. 42, by T. Bellamy, for simple elegance of taste, although it perhaps falls as much too short of adequate decoration, as a great majority of the other designs err in being overloaded and crowded with it.

The subject itself is undoubtedly not a very easy one; nor is it the least difficulty attending it, that artists are left entirely to their own ideas, without anything to guide them, upon an occasion where the only existing precedents are confined to insulated monumental columns; still we trust that, though repulsed, they will not sit down in despair, but that some one will yet produce a design that shall obtain the general suffrages of the public, and of artists themselves.

SCHOOL OF THE ANTIQUE,

MARGARET STREET, CAVENDISH SQUARE.

We took the opportunity of attending some of the lectures on anatomy, by Mr. S. T. Fisher, now in course of delivery at the School of Design, in Margaret street, and we cannot but express our unfeigned gratification at the manner in which they are conducted.

We have never heard a lecturer on this branch of the arts, who, possessing even greater talents and acquirements, afforded such a clear view of the subject as was presented by Mr. Fisher. He seemed to give up all that deep research and extensive knowledge, which he evidently possessed, to devote himself to the inculcation of his instructions in the plainest manner, and the youngest student could not have left the lecture-room without having understood a subject, which men of greater name can only embarrass and confuse.

These instructions were illustrated by most able drawings, casts, skeletons, and the living model, and were conducted with a completeness worthy of an institution, which both in system and material advantages has hardly its parallel in London.

ON THE MEANS GENERALLY EMPLOYED FOR REMOVING RUINOUS BUILDINGS.

We possess many books which contain every information regarding the construction of buildings—from the laying of their foundation-stone up to the completion of their minor details. We are, however, not so well informed as to the method of taking these buildings down when they become ruinous, although it is often a more difficult operation than their erection; and the advantage of being possessed of information on this apparently *out-of-the-way* subject is really greater than a general observer is inclined to believe, more especially when it is considered that many of the houses lately erected have sprung up in an incredibly short space of time, and have been constructed of materials not calculated to withstand the vicissitudes of our tempestuous winters, nor to resist the effects of any sudden accident. It seems to us that the authorities of all large towns should be prepared with means for removing the walls of such buildings when they happen to be suddenly deprived of their usual support by fire, or the failure of any of their parts: and yet, so far as we are aware, no attention whatever has been devoted to this subject—and it is on these grounds that we venture to offer a few remarks on the methods generally employed on such occasions.

In situations where the erection of scaffolding is inexpedient, the methods commonly resorted to are those of pulling down the walls *en masse* by means of chains, and of blasting with gunpowder.

We have seen the first of these methods often put in practice, but never with such signal want of success as about two or three years ago, where a gable wall of rubble masonry, about 50 feet high, 150 feet broad, and perhaps 2 feet thickness, had to be removed. Although forty or fifty persons were engaged pulling and tugging at the end of the chain, prefacing each effort with a *nautical shout*, which they seemed to expect would materially contribute to the efficiency of their exertions, they seldom pulled down considerable masses, and never succeeded in disturbing the equilibrium of the whole mass. There was, indeed, one cause that operated strongly against the success of the experiment, which was, *the want of keeping time with the oscillation of the mass.* Whenever the wall was thrown in the least degree from the perpendicular, the chain should, of course, have been pulled in *concert* with the vibrations, which, being always increased, would at last have thrown the centre of gravity of the greater part without the base, and the whole fabric would then have fallen to the ground. But instead of being pulled by a band of trained men, the rope was subject to the controul of the whole mob, who, by never pulling in concert, rendered their exertions worse than useless. After much time had been lost in these fruitless attempts, *blasting was tried with perfect success.* To those who had never witnessed the effects of gunpowder employed in such a way the plan appeared more hazardous than experience afterwards proved it to be, for *not a stone was thrown ten, or, at most, fifteen feet, from the bottom of the wall,* and in no instance where it has been tried have we ever seen stones scattered to a greater distance.

From this account it will be seen that blasting is by far the most efficient and safe agent that can be employed in levelling ruins. Had the wall been thrown down by a system of pulling, the stones, from the impetus acquired in falling from a vertical to a horizontal position, would have been scattered and thrown to a great distance, at the manifest risk of those who were below, and of the neighbouring houses.

In blasting, the lower courses of the masonry are shattered, and a shock, sufficient to disintegrate, and, sometimes, even bodily to lift up the superincumbent mass, is propagated from top to bottom. The dangers to be apprehended are, first, the possibility of one or more of the stones being thrown to some distance; and, second, the possibility of only some part of the lower courses being blown out, while the remainder is left; so that the wall is apt to turn on that part as a centre; in which case it may appear probable it would fall in the direction in which there was no support.

First.—The danger of one or more of the stones being thrown to a distance seems a probable one; but, in so far as *our* observation has gone, this has never occurred. The action in blasting a solid mass of rock, is different, we think, from blowing up an artificial concrete-like masonry; for, in the one case, the gases formed by the explosion have no room to expand themselves, unless by rending the compact rock, whose particles are cemented in the closest union; while, in the other case, there are numerous fissures, affording much greater room for expansion.

Second.—The second danger is little to be dreaded, as the whole of the lower courses are always either completely removed, or else so shattered as to yield to the slightest pressure. But in every case which has come under our observation, the wall itself has been *at least* perfectly disunited from top to bottom, by the shock resulting from the blast.

Although we can easily conceive the possibility of either or both of these accidents occurring, still we think ourselves perfectly justified in decidedly recommending blasting in preference to the other methods we have alluded to. We do so, not because we have arrived at that conclusion by any reflection on the subject, nor yet because we have heard it praised by those whose opinion, as practical men, is to be valued, but because we have ourselves been witnesses of its effects.

It must, however be observed, that without judicious superintendence, this powerful instrument (like all others) may, from incautious application, prove in the highest degree destructive in its effects. Prudence in the selection of situations for the bore, and caution in charging and firing are indispensable requisites for safety; and even where attention is paid to all these essentials many unforeseen circumstances may, no doubt, occasion what all possible care could not prevent.

We may state, in conclusion, that although some may consider the removal of ruinous walls as not an operation in which engineers or architects are ever, or at least often, to be engaged, we think that ought in no way to make these remarks the less important; for any sudden accident *may* render peremptory measures necessary, and upon the success of these measures valuable property, and even human life, may depend.

PANORAMAS OF ROME AND THE COLISEUM.

The two subjects now exhibiting in Leicester-square have claim upon our notice, as being of considerable architectural interest; the one as a general representation of Rome, showing all the buildings visible from the tower of the Campidoglio, on which the spectator is supposed to stand; the other, of that wonderful fabric, the Coliseum, whose interior, with its arena, is shown as beheld from the top of its walls at its southern extremity, whence the eye also looks down upon the neighbouring arch of Constantine, and several other edifices. Although the smaller of the two, and of less variety of interest in its subject, this painting is more striking and captivating than the other, in regard to scenic effect and the illusion it produces. It conveys a most perfect idea—at least as perfect as can be obtained from the single spot to which the spectator is fixed—of the structure in its present state, of its prodigious massiveness, and of the ancient Roman brickwork of which it is composed. The look of reality is quite astonishing, and the more we contemplate the building, or parts of it, the more does it increase. Yet it is puzzling to account for the extraordinary relief, there being little of positive shadow, since even the parts on which the sun does not fall are shown as distinctly as in ordinary daylight, owing to the strong reflection which renders their local colouring visible in all its hues. The other view is not so remarkable for this deceptive quality, for though admirably executed it has not so vivid an air of reality, being apparently painted in a lower key. Perhaps, too, something may be owing to the subject itself, as being less favourable to illusion. Still there are parts of prodigious effect—for instance, the two side buildings or wings of the Campidoglio, immediately beneath the spectator, seen as he looks down upon them from the tower in the centre one. Again, the dome of the small church, close by Trajan's column, is of most forcible relief. By specifying these instances, we do not mean to say that the rest of the picture is not so well painted, but the two buildings we have mentioned, being much nearer than most of the others, of course show themselves more distinctly. St. Peter's is too remote to be a principal architectural object; but in a view taken from the Castle of St. Angelo, both that and the Vatican would be very prominent objects, and occupy a considerable portion of the scene. In our opinion, such other general view of Rome would be —we will not say worthy of Mr. Burford's pencil, since of that there can be no doubt—but eminently attractive to the public; nor at all the less so, because preceded by the one he is now exhibiting.

ISOLATED HARBOURS OF REFUGE.

In the last number of the Engineer and Architect's Journal, p. 85, Mr. Rooke remarks that, as there is no tidal scour provided for the interior of Mr. Tait's isolated harbour, although shingle could be disposed of along shore, "might not," he says, "silt eventually choke up such a harbour?"

Why, the very same remark might, with nearly equal propriety, be applied to a wet dock. Water admitted into a dock or harbour, must be pure indeed not to deposit while there, in a state of comparative rest, a sediment of earthy or other matter in twenty or thirty years time. This of course was to be anticipated. It is obvious, however, that there can be no difficulty in removing such silt by dredging, or otherwise, at no great expense, whenever it shall be found to be inconvenient; and it is important to observe here, that the process of dredging can be carried on in the harbour during all hours and during all times of tide, until finished, without interfering, in any shape whatever, with the essential purposes of the harbour.* Vessels are neither interrupted by it in coming in, nor in going out. The mouth of the harbour, if properly carried out, as it ought to be, into deep water, is kept free and open, and accessible at all times and in all weathers. It would be a very different affair, however, if, instead of the scouring power being confined and directed towards *the rear of the harbour*, as designed by Mr. Tait, it were allowed to cross the mouth or entrance of it, as at Dover, &c., and a bar of shingle or sand allowed, in consequence, to be formed there.†

Mr. Tait's principal object is to prevent the shingle moving, as it does, along shore, from getting into, or even near the mouth of his harbour. This he proposes to accomplish by facilitating the passage of the shingle along shore and in the rear of his harbour, and as far as possible from its entrance. He has, therefore, studiously avoided all tidal or any other scour whatever within his harbour.

Mr. Rooke next says, "The uncertainty of the plan," (Mr. Tait's isolated harbour,) "its obvious expensiveness, its distance from the shore, and an exposed locality, however ingenious and able the scheme may be, involves objections which are more easily started than answered." If these remarks have special reference to the formation of a harbour at Hastings, they may perhaps be, in part, true. It is quite impossible, however, to form any decided opinion on this point, without being well acquainted in the first instance with the whole *locale* of a place: its tides, currents, prevailing winds, soundings, line of coast: its exposed projections, or sheltered indentations, &c.

In order to have the mouth of an isolated harbour in a sufficient depth of water, so as to be accessible at all times of tide, such a harbour at Hastings, would, very possibly, require to be carried out to some distance from the shore, and consequently to an exposed locality; attended, of course, with a certain proportionate increase of expense. But, as to its "certainty," Mr. Rooke may be assured, that its certainty would depend entirely on the strength and distribution of the materials, and workmanship, &c. used in its construction; and would be totally independent of the principle upon which the harbour is designed. The "certainty" involves a mere matter of judicious calculation of the strength and disposition of certain materials capable of resisting certain permanent and probable forces. As to the "expensiveness" of such a harbour. Mr. Tait has never upheld his harbour on the score of its cheapness. Quite the contrary. But at the same time, there might be situations found, perhaps, (were that an object,) where an isolated harbour could be constructed as cheaply as any other. However, it must be allowed that in ordinary circumstances, his harbour is much more likely to exceed, than to fall short of the expense, at which harbours, at the debouchure of a stream, might be constructed on the old and exploded system of scouring by means of backwater, &c. Cheapness is not, in fact, the object aimed at. The chief object, in view, is to have a harbour, at a fair adequate expense, which shall not be liable to be closed up by a bar at its entrance, and be thereby rendered inacessible in the hour of need; but such a harbour as shall be open to receive, and shelter, and protect vessels, in distress at all times of tide, and during all kind of weather.

ZERO.

[The result of Mr. Tait's advocacy of the doctrine of isolation, vol. i., p. 337, has certainly been to insure its general reception as a principle of science, and we have no doubt that it will eventually be employed both extensively and beneficially. Mr. Rooke's communication has suggested a new feature, the construction of a harbour by a series of experiments, and it presents many useful points. There is little doubt that in Mr. Rooke's plan, vol. 2, p. 85, S. W. winds would produce a ground swell, or as it is called in the Channel Islands "a race;" but that is only one side of the question, for harbours are in this respect of two kinds, either of general refuge, or shelter against prevailing winds. To provide shelter against the S. W. winds, we should recommend that in the harbour F, the entrance N should be stopped, and another opened at B, and if necessary the east groin A might be removed to G. With regard to the question of the silt, we cannot take upon ourselves to decide, as that will vary according to position; the facts brought forward by Mr. Hyde Clarke prove the accuracy of the principle, although we have not yet sufficient data to ascertain whether the same results would be obtained upon the sandy coasts of England as in the depths of the ocean. By the progress of science, the engineer may be furnished with power greater than is conceivable at present, and we have pointed out in our present volume, p. 38, the manner in which the success of Mitchell's screws may be brought to bear on this important subject. One useful lesson we may learn from this discussion, that engineering is not a mere matter of bricks and mortar, and that as there is no book from which we cannot learn something, so there is no fact, however trivial, which does not belong to the domain of science.—Ed. C. E. & A. J.]

* This is very material to be kept in mind.

† Every time that such a bar is formed, it is obvious that the harbour becomes thereby useless; and such a bar may be formed in one tide; and no sooner removed than formed again by the very next tide. But it cannot be removed at all at Dover during the whole period of neap tides. It can only be removed during the height of spring tides. So much for depending on the effect of culverts. The harbours on the South Eastern coast of this great maritime nation ought to be independent of any such trumpery.

NELSON MONUMENT.

Sir, — Having carefully observed the marvellous inequality of talent manifest in the designs sent in competition for the Nelson monument; and that, with a few splendid exceptions, those men who take anything like rank as artists or architects in general estimation, have considered this contest of skill as beneath their notice, and left it for those who have higher feeling and less conceit, as well as for mere aspirants to engage in; I have asked myself how or why it has happened that a call which ought to have aroused the most torpid, has, upon the whole, been so unproductive? And I cannot but think, that, gloze it how they will, a mean and sordid pride, a trembling, lest, by some mischance, an unknown man should pluck the honour from their brows; or, mayhap, a more selfish spirit still, has actuated them.

As an Englishman, I deplore that talent, which is known to exist, should thus miserably extinguish itself; and whatever be the result of this competition—be the design which is to have the first premium executed or not—as an Englishman, I do hope that some more adequate mode of eliciting the talent of the country will be devised.

In this case, the committee began by acting with the best and noblest feeling. They advertised for designs. Their only error—and pardonable indeed it was—consisted in not at once defining what species of monument they wished. Still, they left the road open; and so fair an invitation would have lured many to try, confident that if their designs were best, they would not only have the honour, but the profit of its execution. Some evil spirit, however, affected the committee, and their first right step was followed by a wrong one. They again advertised, *and offered premiums*. This was bad enough, but they made it still worse, by adding, "but no further reward will be given;" thus distinctly and unequivocally giving the professions occasion to infer, that, however good the design, however honourable the successful man might be, he was not to execute his own work, but that some other man was to be fattened on the honey which his labour was to create.

I, sir, have not the honour of being an artist; I may not be so sensitive as men of genius are apt to be, but that was my interpretation of the words immediately that I saw them; and I doubt not that others felt the same, and that their emulation was palsied by it. Had not this been done, and had ample time, in the first instance, have been given, instead of driving artists to work upon the crude first conceptions, that their designs might be ready in about *two months*, and then adding *six months* more, I quite expect that a greater number of good designs would have been sent in. Rely upon it, sir, the wreath of fame has more and better followers than the purse of wealth; and be assured that many of the competitors were more incited by the hope that, notwithstanding the ill omen, they would be chosen to conduct their own design, than by the expectation of so much cash in hand. I cannot and will not doubt that the committee were actuated by the best motives in what they did. I only point out what I conceive to be the evil of their so doing; and, having done so, may I venture to propose, through you, to the public, that, in the event of other competitions being required, a middle course should be taken; which, while it may, to a great extent, secure the efforts of men of high rank, will not shut out others who may be equally talented and equally honourable, although not equally known to the world; and thus I would say:—Let a committee select a dozen artists or architects of good repute, and covenant to pay each some certain sum, sufficient just to cover the manual labour of making their designs, and engage to employ the successful artist to execute his work. In addition to this, let them advertise for designs, offering no definite premium, but promising that, if one of such designs be chosen, they will reward the author; and, if he produce proof of his constructive skill and integrity, they will also employ him to complete the work. It appears to me, sir, that, by so doing, a committee would not only secure good designs from men of high standing, but have a fair chance of eliciting unknown genius, and that, in such a manner, as no man of good feeling, however high his professional rank, could object to. There is one point, however, I would beg to impress upon committees—that, on no account should they admit drawings finished in any other than Indian ink or sepia. They should be neatly outlined, and the shades lightly washed in, and free from any of those dabs and touches, which are not only untrue to nature, but give a meretricious effect to designs which are in themselves valueless. If it were not so, how do these very dabs, stainings, and sharp touches make "a landscape of a post?" I would next follow the example of the committee on the designs for the Nelson monument; first adjudicate upon them, and then admit the competitors and the public to view; for I am quite assured that, let artists say what they will, the public, as a mass, are the best judges. Individuals may think oppositely, but a large number of conflicting opinions in some strange way neutralise each other, so that in the result the decision of public opinion is generally that which is most consonant with propriety and justice: and even if public opinion were erroneous, such a course would tend much, if not altogether, to remove those suspicions of favouritism, and forestalled judgment, which in many instances, it is to be feared, have been but too well-founded. I am quite aware that other practices than those of prejudgment exist, and practices against which nothing can guard but the utmost care that committees shall consist of men of honour. It is quite within their power to give one public set of instructions, and privately to give some favoured artist more detailed information. It is quite practicable to send for an artist after the designs have been sent in, and direct him to make certain alterations which shall improve his drawings or his model. These are dishonourable acts which, like other dark deeds, often betray their perpetrators; and they fall deeper than ever they rose higher in consequence of them.

Such practices must in process of time prove their own correctors, and so that artists be but true to themselves, and every individual strive to keep his own honour immaculate, it will not be long before generous competition shall raise this portion of the repute of Britain, and rank her as high in art as the efforts of Nelson and Wellington have placed her in naval and military renown.

I have the honour to be, yours, &c.,

OMEGA.

BIRMINGHAM AND GLOUCESTER RAILWAY ENGINES.

Worcester, 8th March, 1839.

Sir,—In No. 18 of the "Civil Engineer's and Architect's Journal" for March 1839, at page 116, you volunteer an editorial paragraph, conveying reflections upon the Birmingham and Gloucester Railway Company.

Had you referred to the reports of the last half-yearly meeting of this company, held on the 12th February, which reports were published in the Birmingham and also in the Gloucester journals of the same week, you would have seen a correct statement of those facts upon which your comments referred to have been erroneously made.

The facts are, that Mr. Norris, a locomotive engine-maker of high reputation in America, has engaged to send upon trial to England a locomotive engine, which shall perform a much greater amount of work, under certain specified conditions, than engines of similar class and expense are at present performing upon the railways of this country.

If this trial succeed, agreeably with the stipulations and to the satisfaction of the company's engineer, the company purchase the engine.

If the trial does not succeed, Mr. Norris pays the expenses attendant on the trial, and the company remain in the same situation in point of expense as that which they held before the trial was made; that is, they pay for nothing.

The company engage to take ten engines in all under the above conditions, which are applicable to each engine, as each arrives from America.

Having now given you the facts, allow me to add, in reply to your comments:—The Birmingham and Gloucester Company do expect that Englishmen will support their projects so long as those projects bear out the principle of procuring the best possible article at the least possible cost,—no matter whether the cost be paid to an American for engines, or to a Norwegian for timber, the latter being a process by which (to use your own phrase) "the money subscribed goes out of the country," under the sanction of numerous railway companies, who appear hitherto to have escaped your condemnation.

The Birmingham and Gloucester Company do not "expect that the public will have any confidence in the safety" of these American engines, until they shall have been subjected to the trial above referred to, which will fully prove this point; but the public may probably be aware of the broad fact, that safety, so far as the results of *locomotive engines* are concerned, is upon a par in both countries, and both the public and yourself will, I have no doubt, cordially rejoice in the advancement of practical science, which the results of these trials, if successful, will evince.

I apologise for trespassing thus on your space, and am, Sir, your obedient,

W. S. MOORSOM, Engineer.

THE ROYAL EXCHANGE.

Sir,—Is it possible that there can be any truth or approach to truth in the following paragraph, which I quote from the "Sunday Times," where the "Morning Advertiser" is named as the authority for it? "We are happy to learn that Mr. Baily's design for the New Royal Exchange is that which is to be adopted. The Gresham committee have at length yielded to the views of the Chancellor of the Exchequer on the subject. Mr. Baily is the most distinguished artist of his day in his own peculiar walk; and the admirers of genius must be grateful to him for asserting its rights in the person of Mr. Baily." Whether this be intended seriously, and merely a blunder, or whether it be intended as a joke, it is difficult to guess. It certainly would be very odd that Mr. Baily's, or Mr. Anybody-else's, model should be chosen before anything was known when designs were to be sent in. The writer of the paragraph, however, may know a great deal more of the matter than any one else, for he knows, it seems, and is willing to let the world know, that "Mr. Baily is *the most distinguished artist of his day*, in his own peculiar walk." Nevertheless, I must confess, I never heard the name before as that of an architect; therefore if distinguished at all, it must be by the obscurity in which it has been shrouded. Neither have I any idea what can be this most distinguished Mr. Baily's own peculiar walk, unless it is meant that he has been in the habit of attending Change, and showing himself in one particular *walk* there. Another puzzle is to know to whom the admirers of genius—that is, of course, all of us, have to be grateful to for asserting its rights in the person of Mr. Baily; is it to the distinguished artist himself, or the Chancellor of the Exchequer?

Pray endeavour to unriddle the whole of this enigmatical matter, if only that we may get out of debt at once, by paying our gratitude in the proper quarter.

In the mean while I remain,
Your most undistinguished
READER.

SAVERY AND TREVITHICK.

Sir,—Several periodicals, last week, gave an analysis of an essay, that had been read by Professor Regaud, before the Ashmolean Society, on some circumstances in the history of Captain Savery, the inventor of a steam engine. I read the analysis in the *Literary Gazette*, the editor of which observed, that Savery wrote the *Miner's Friend* to draw attention to his engine, and that this book "is now a very rare volume. It is in the British Museum, and we believe a copy will be found in All Souls' College Library. Surely in the present day of science, and of scientific mining in particular, a *republication* might be very useful: and would be infinitely more valuable if the professor of astronomy (the only person we know who is calculated, from his love of minute research, and the vast accumulation he has made of materials, to do justice to scientific biography,) would prefix his notices of the author and his invention."

From the recommendation in this paragraph, it is clear the editor of the *Literary Gazette* has never seen the *reprint* of the *Miner's Friend*, made in 1827, by Mr. Robert Meikleham, from a copy of Savery's book in his possession. The first edition, dated 1702, is in 12mo, and has one large folio engraving, showing a perspective view of the engine. This engraving was either borrowed from Harris's Lexicon Ledinicum, or Savery gave the plate used in the *Miner's Friend* to Harris. The impressions are identical. Mr. Meikleham's edition is in 18mo, and when compared with the original, it has some pretensions to elegance: it has three engravings, and eighteen ornamental vignettes. A small number only were printed, which were purchased, I think, by Mr. Reid, bookseller, Charing-cross. Some of the copies had a portrait, designated as that of Savery. This, however, is a misnomer, occasioned by the letter-engraver affixing the name to a wrong portrait; and the mistake was not discovered till it was too late to rectify it. Mr. Meikleham had an original portrait of the Captain, which he procured in 1816 from a Mrs. Boughton, of Boughton, who was connected with Savery by marriage. At that time she was very aged, and having outlived some benevolent relations she had fallen into great poverty. Mrs. Boughton knew nothing of Savery's history; she remembered her father-in-law speaking of him as having had the reputation of being a very self-willed and passionate man; very niggardly and selfish; and that he had been sheriff of Devon. This, however, was a palpable mistake. The portrait in her possession had been painted with considerable freedom, and when Savery might have been between thirty and forty years of age. Although much mutilated, the face was perfect; so was the upper part of the peruke, and a part of the cravat. It had not been preserved from a feeling of its value, but for its convenience as a piece of furniture. The effigy had served as a chimney-board. On cleaning it, there was found written on the canvas frame: "No. 7. Mr. Savary, ingineer." It had certainly at one time been in some inventory, perhaps in a sheriff's. An engraving was made from this portrait for my compilation, but, the artist not having made a passable transcript, his copy was cancelled.

Professor Regaud also mentioned, that no trace of Savery having been a partner with Newcomen is to be found in the Rolls Office. This may be. In a search made twelve years ago, to ascertain the point, I could not find even Newcomen's patent. Perhaps I inquired in the wrong quarter, in the Patent Office of Extortion. I gave, in a note, Swebre's account, which he wrote twelve years after Savery's death. In the text I said that, "His (Savery's) interest was consulted by associating his name with that of Newcomen and Calley in the patent." Mr. Richard Lovel Edgworth had used the same words in a letter to the editor of a periodical, in some discussion on the history of the mechanism. But after all, Savery may have been a sharer, as Switzer says, in the profits, without his name appearing (as I, perhaps, wrongly express it) in the patent. The date of Newcomen's death has not been ascertained. In 1730, he is spoken of as the "late Mr. Newcomen." Calley died two years after Savery. The professor styles Savery a "military engineer." I know not what that profession was in Savery's time. He assuredly was a civilian. Sir Isaac Newton, who knew him, calls him "Mr. Savery." When I was engaged, in 1825, in the preparation of the "Anecdotes of Steam Engines," Mrs. Broughton became an object of great interest. I anticipated being able, with her assistance, to get into some channel of information respecting Savery, but all my enquiries *then* to learn where she was, or if alive, were unsuccessful; every trace was obliterated.

I was highly gratified with the memoir of Mr. Trevithick in your Journal for March. I believe, but I speak from an uncertain recollection, that the late Dr. Tilloch, editor of the "Philosophical Magazine," had some share in the project of sending high pressure steam-engines to Peru. He lost money by his adventure, for the most magnificent Spanish promises would not "take up" the smallest acceptance on the silver mine-engine account, in London. Among Mr. Trevithick's inventions was an elegant machine for producing a reciprocating motion by a fall of water, without losing the effect of a single *drop* of the fluid!! He exhibited a model of his machine of which I have a drawing. The water acted on the piston like the steam on the piston of his engine. It was a kind of *pet* project among mechanics at this period to supersede water-wheels! Trevithick's column, a *thousand feet high*, would be just the thing now in Trafalgar square. It would be a worthy monument to a truly great man, designed by one much greater. Some account of this, I doubt not, would amuse your architectural readers. Your correspondent, who, in his memoir, has done such good and acceptable service to all mechanics, *must* be in possession of many anecdotes concerning his friend, and he will indeed do great injury to his memory if he fail to chronicle them. The slightest incident in the life of such a man as Trevithick is invaluable, for his name is an historical one, and his fame is interwoven with that of the greatness of his country.

I am, sir, your most obedient servant,

19th March, 1839. ROBERT STUART.

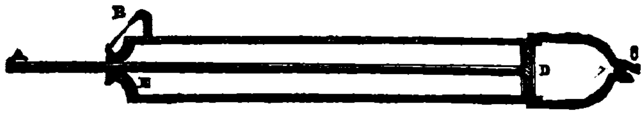
THE DYNAMOMETER.

Sir,—Having never seen an instrument of this kind which I conceive well calculated to prove the draught of a plough or road carriage in a satisfactory manner, I beg leave to trouble you with a description and sketch of one which I think might answer the purpose.

The common Dynamometer is deficient, as it only shows the strain *at a particular moment*, and is constantly varying during the trial, so that at the end of the experiment the *average strain* cannot be calculated. To ascertain this it would be necessary during a trial to note *every variation* indicated by the instrument and *its time of duration*, which sometimes might amount to several, in one second of time.

Such being the case, the desideratum seems to be an instrument that will *sum up in one* the whole force exerted during the performance of a piece of work, or during a given time, at a certain rate of speed. Suppose, for example, the plough to be tried, I would have the instrument to show what strain was exerted in drawing a furrow from one to the other end of the ridge, taking care always to *note the time* in which this was performed. If tried upon a carriage, either upon a rail or common road, take, for instance, a mile or two, at any rate of speed most convenient, the instrument wanted is *to collect into one, and exhibit at one view* the power expended during the trial.

My plan is as follows:—To make a strong brass tube, of any convenient length, bored perfectly smooth within, and of such a diameter as might be found to answer; this tube to be open at the one end to admit a tight-fitted piston with a polished rod, which would go through a collar or small opening at the other end; the apparatus would, in fact, be a model of the cylinder, piston, and piston rod of a steam engine. The following sketch will better explain it; the tube is meant to be filled with water, which, by the draught at A, is to be ejected at the small bent tube B, at a very small orifice.



This arrangement being made, the instrument is yoked to the plough or carriage at C, and the power applied at A, the piston D advances slowly towards E, forcing out the water in a very small jet at B, the discharge of which will always be in proportion to the strain applied at A, to overcome the resistance at C. Now, at the end of any *given time*, or *given distance*, the water discharged would be the measure of the force exerted in drawing the carriage or plough, and which of the machines in competition that performed the work in the *same time*, with the least discharge of water in a *given space*, would be that of easiest draught, in other words, the best plough or carriage.

As there would necessarily be a considerable degree of friction in this instrument, on account of the tightness of the piston and collar, required to keep the water from escaping, it might be proper to ascertain the amount of this, which could easily be done by putting the instrument to a balance or steelyard when emptied of the water, which would soon determine the friction in pounds.

The strain exerted in any trial of any machine might also be determined, and an average in pounds taken, by attaching the instrument in the same manner when full, to a steelyard or balance, and by loading it with such a weight as would cause it to discharge *the same quantity of water in the same time* as was done in the experiment with the cart or plough. The friction, as a matter of course, would be to take from each to determine the positive strain.

A scale might easily be attached to the instrument to determine the exact distance the piston might move in any trial.

There may, perhaps, be some difficulty in making the instrument perfectly water tight at the piston and collar, but in my opinion a slight leakage would be of little consequence as this would always be in proportion to the strain to which it might be subjected, and, therefore, not affect the result.

I am not aware that such an instrument has ever been tried, excepting what I have myself done, and that was upon a very small scale; but I humbly think that were such an instrument perfected that it would be highly useful for the proving of plough and carriages of every description, as then the merits of two competing machines might be proved and determined in such a manner as to prevent all cavil, being, in fact, brought to a mathematical demonstration.

Should you think this communication worth a place in your excellent journal, I may, perhaps, trouble you again.

I am, Sir,
Your most obedient Servant,
N. H.

Roxburghshire, Scotland, March 15, 1839.

RAILWAY CURVES.

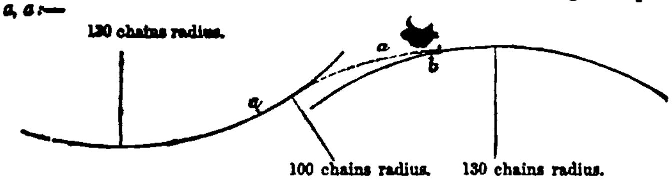
Sir,—Having made use of the plan recommended by "A Sub." in your January number, and being convinced of its practical utility, I make no apology for forwarding you a few remarks upon the objections urged by your correspondent R. W. T. Your correspondent's observation "that if the curvature is not equable some part of it must be *sharper* than if the same radius were used all through" is incorrect, the object being (if I understand correctly the plan of "A Sub.") to begin curving sooner, and make the radii of portions of the curve *greater*. I must also dissent from the assertion that when an engine is entering upon a curve it will not be affected by the nature of the path it was previously describing; for if this be the case, why is the effect of wear and tear of the OUTER rail at the COMMENCEMENT of a sharp curve *less* when the previous path is a curve in an opposite direction (forming an S) than when it is a straight line? Again: Gravity acts upon a locomotive with the same effect as upon a projectile, viz., to bring it to a state of rest. Now althought an engine cannot, like a cannon ball or other projectile, approach nearer the centre of the force acting upon it, yet, *prima facie*, the vertical pressure upon the rails increases as the squares of the velocities decrease. The cases, therefore, are not so dissimilar as I was at first led to believe from your correspondent's observations.

March 15, 1839. J. ELY.

RAILWAY CURVES.

SIR,—As a subscriber to your truly valuable journal, I trust you will not deem me too presumptuous in seeking for the following information through your journal :—

Query.—The most correct mode for placing a curve of 100 chains radius between (? to form) an *S* curve, as in the following example, *a, a* :—



would it not be desirable to reverse the curve towards *b ?*

Mr. Bruff's mode for setting out half-widths (when sidelong) for a line of railway is *very tedious*. I wish he would inform us if there be not a shorter mode than working, as he says, *from every centre peg*.

Query.—Which is the most correct mode of setting out railway curves?

The method adopted on many lines of railway for determining the offset of curves at every chain is thus—tangent squared, divided by radius, will give the versed sine.*

For example—160 chains radius $\frac{t^2}{r} = \frac{1^2}{160} = \cdot 00625$, the decimal proportion of a chain = versed sine at one chain. By reducing the decimal to inches will give 4·95 inches for the versed sine.

This will be, I believe, 1 foot 8 inches for 2 chains. If I am correct, thus, $2^2 \times 4{\cdot}95 = 19{\cdot}80$ inches, or nearly 1 foot 8 inches.

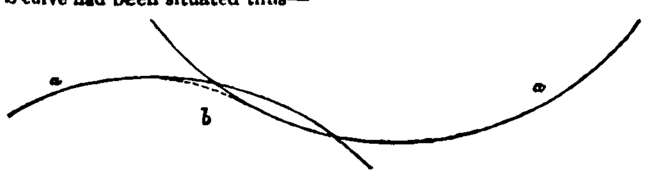
Hoping to see these matters explained in your next number,

I remain, your very obliged servant,

15th March, 1839. AN ASSISTANT ENGINEER.

[We have altered our correspondent's communication, so as to make it better understood by our readers; and we also referred his letter to Mr. Bruff for an explanation of that part relative to setting out "widths," and have received the following reply; and we have also obtained Mr. Weale's permission to copy from his "Scientific Advertiser" Mr. Charlton's communication on setting out railway curves, which we have given below.—EDITOR.]

SIR,—In reply to your correspondent, "An Assistant Engineer," as to the most correct method of carrying into effect the question he propounds, I am not sufficiently in possession of the case to answer it with satisfaction to him or myself. From the hurried glance I have given at his letter, I presume the two curves *a, a*, were intended to have met, and he now proposes to effect a junction, by laying out another curve of 100 chains radius. If this is the case, why not connect them with a tangent? or if this is not possible, with a short tangent and a curve reversed; but if he is compelled to connect by a *S* curve, most undoubtedly it should be reversed as your correspondent suggests. If the *S* curve had been situated thus—



a, a, the two curves, and *b* the point where the junction was desired, it could easily have been connected by adopting a single curve of less radius, having a common tangent at the connecting points.

With respect to your correspondent's complaints of the method I have communicated of setting out widths on sidelong ground being tedious, and requiring a shorter method, "I have no help for him." On ground that is at all variable, even a distance of 100 feet is too great for cross sections, and I often take one or two intermediate sections in that distance when in cutting; in embankment I consider such nicety of little moment. I have for some time past had charge of a railway contract of something less than five miles, the whole of which is on sidelong ground of a very abrupt character; and, after trying various plans for taking the cross sections, (which was here absolutely necessary in determining the extent of ground to be taken,) I was fully satisfied that the method I have detailed in your journal was not only the most correct, but the quickest and most easy of execution of any that I am aware of or have seen practised. I have levelled centre stakes throughout this distance, and determined the widths as I have described, and as a great portion of the works have now been carried into execution, (the cutting in some places being as much as 50 feet,) I can speak with increased confidence of the accuracy of the method.

The methods adopted for laying out curves are various. Your correspondent, by referring to the "Railway Magazine" for January, February, and March of last year, will find several excellent methods detailed, as also in "Weale's Scientific Advertiser" for May last.

I remain, yours, very truly,

PETER BRUFF.

Charlotte-street, Bloomsbury, March 21st, 1839.

* Nothing can be more erroneous.—ED.

The following communication we extract from "Weale's Scientific Advertiser :—

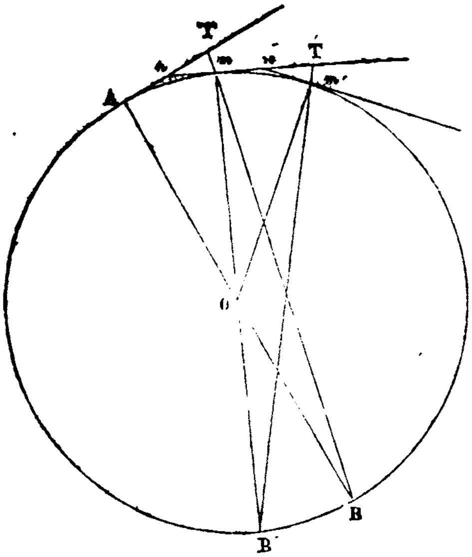
The all-important subject of railways seems to engross the almost exclusive attention of both the scientific man and the practical mechanic. Railways at present are only in their infancy, and probably many of the methods now in use for laying down rails, setting out curves, &c., will in a short time give way to other inventions better adapted for practice, and of more general utility. The different methods adopted for setting out curves seem to demand much more attention than engineers have bestowed upon them. To have a curve on a railway, is at best a *misfortune*, and ought never to be resorted to unless to avoid some greater evil. Admitting the curve to be a true circular arc, and correctly set out, each carriage in a train will have a continual tendency to fly off, and that tendency will be increased or diminished in proportion to the diameter of the circle of which the curve is a segment. The distance between the wheels on each side of a carriage is a straight line, but the wheels and carriage are forced to move in a curvilinear direction ; the friction, therefore, between the wheels and the rails, especially in an arc of a small circle, must retard the progress of the train, wear the materials, strain the carriages, and greatly increase the chance of accidents, from the trains being thrown off the rails. All this will necessarily take place when the curve is correctly set out ; but what must be the consequence when the curve is not uniform in its curvature? Probably some portion of it nearly a straight line, another portion of a four-mile radius, another a segment of a quarter of a mile radius, and another of no known curve whatever. A train forced along a line thus formed with the usual speed, runs a great risk of being thrown off, besides the incalculable injury done to the carriages. It is, therefore, of the deepest importance that engineers and surveyors should have a true method of setting out curves, and it is worthy of remark that the methods founded on true principles are *easier* than those founded on false ones, and require much less trouble in practice. The foregoing renders a theodolite unnecessary, nor does the surveyor require any instrument except a chain and two or three poles. In hilly countries it is only necessary to ascertain the elevation or depression of any place above or below the point where the curve commences, and that will be the side of a triangle, the ratio of whose sides are given. To illustrate this without a diagram, suppose the slope in a cutting rise 2 feet in 3, and that the elevation of a hill above the point of commencement, or the last point found by the surveyor, should be 10 feet ; then, having ascertained a point on the hill as if it were explained according to the foregoing method, say as 2 : 3 : : 10 : 15 feet ; this 15 feet must be measured back from the point already found in a direction perpendicular to the line of railway, and thus a true point in the curve in its progress over the hill will be readily ascertained.

The rule made use of in several railways is, *to divide the tangent in inches by twice the radius of the circle* ; or, which is the same thing, *divide the square of the tangent by the diameter of the circle, and the quotient will be a perpendicular offset to the curve !* To any person at all conversant with geometry, this method will be seen to be manifestly erroneous : however short the tangent, it is not true ; but if, as mentioned by Mr. Terry, in the "Railway Magazine," a few months back, the tangent should be five chains, then this method of finding an offset is *grossly erroneous*, and, in a matter of such consequence, ought at once to be abandoned, and a true method substituted. It was lately decided by the Chancellor, in a railway case for libel, that the *acquirements* even of the secretary of any public company were legally subject to be fairly inquired into. If such then be law as it respects a secretary, surely the acquirements of the principal engineer of a railway, touching his mathematical and mechanical knowledge, are a subject of fair and legitimate inquiry, and more especially when it is considered that want of such knowledge on his part may affect the interests and property of the parties amounting to millions of money.

FOSTER CHARLTON, Weybridge.

A PRACTICAL METHOD OF SETTING OUT A CIRCULAR RAILWAY CURVE,

WITHOUT THE USE OF ANY INSTRUMENT FOR TAKING ANGLES.



Let A be the commencement of a circular curve: perpendicular to the radius AO measure any distance AT, and from *n* the middle of AT measure *n m* equal to A*n* or *n* T meeting $Tm = AT^2 \div \sqrt{AT^2 + 2AO^2}$, then will *m* be a point in the curve. Again, measure in the direction of *m m'* to T' making *m* T' = AT, and from T' the middle of *m* T' measure $n'm' = n'T'$, or *n'm* meeting $T'm' = Tm$, then will *m'* be another point in the curve, and thus any number of equidistant points may be found.

DEMONSTRATION.—Because $Tm \times BT = AT^2$, and $TB^2 = \overline{AT^2 + 2AO^2}$, we have $Tm = AT^2 \div \sqrt{AT^2 + 2AO^2}$, then will *m* be a point in the curve. Again, join O*m* and A*m*, then since $Tn = nm = nA$, the point *n* is the centre of a circle passing through A, *m*, T; therefore A*m* is perpendicular to T*m*, and *n m* a tangent to the curve at *m*.

The method of proceeding on the concave side of the curve is equally easy, and depends on the same geometrical principles. The foregoing supersedes the necessity of taking any angles. The methods given for laying out curves in the March and preceding "Railway Magazines," though founded on true principles, require either a theodolite or a table of sines and tangents, while this method requires neither, and appears simpler and more fitted for practice than any I have seen.

HISTORY OF PAPERHANGINGS.

Extracts from a paper by Mr. CRACE, *read before the Royal Institute of British Architects.*

(Continued from page 100.)

In the former paper I endeavoured to trace the *history* of the art of paperstaining up to the present time, and it is now my purpose to describe the manufacture, and give some account of the modern improvements that have been introduced.

In that paper I showed, I trust satisfactorily, that the flock papers, or rather hangings, were introduced into England in the time of Charles I., and that a person named John Lanyer obtained a patent for the invention in 1634. I also cited an article from an old French dictionary of commerce, proving that the coloured paperhangings were made at any rate in that country in the seventeenth century, and referring to statutes relating to them even of the date 1586.

There were formerly three modes in which paperhangings were manufactured. By printing the outline with blocks and then colouring by hand; by stenciling; and by blocks alone.

The first of these methods is that described in my former paper, under the head of Dominoterie.

The second, stenciling, is performed by cutting out either in paper, leather, or other materials, the pattern intended to be represented, and then, placing this on the prepared ground, brushing it over with the proper colour. This mode gives an imperfect outline, and is now discontinued in paperstaining, and merely sometimes employed by plasterers to ornament coloured walls.

The third is the mode now almost universally adopted in this manufacture, whereby every colour is applied by a separate block, according to the tints and shadows intended to be represented.

I have before said that Lanyer's patent did not even mention paper among the substances on which flock could be applied, as it was at that period of too rotten and bad a quality to bear the weight of the woollen material. But paper has now been brought to so high a degree of perfection that it is the only substance employed, and has thus assisted greatly the operations of the paperstainer. Till within the last twelve years the pieces of paperhangings were formed of sheets, each about three quarters of a yard long, pasted together till the proper length of twelve yards was completed. This method was attended with many inconveniences, the joints rising, or being imperfect, and generally showing, all which evils are now remedied by the pieces consisting of one perfect length of paper, without any joints whatever; the width, too, can be enlarged to two or three times the ordinary size, as is now repeatedly done in France, as these examples will show, though we have not as yet adopted this plan.

The modern coloured papers are almost all worked in distemper, or colour mixed with size to bind it, instead of with oil or varnish, which was more employed formerly, and is now, in fact, used in the manufacture of the washable paperhangings; the effect of them, however, is not nearly so clear and brilliant as in those worked by the former method.

Distemper, or body colour, is generally thus prepared:—Whiting finely powdered and soaked in water is first well mixed, as stiffly as it can be worked, and then stained with the proper colours well ground in water; when the desired tint is produced, double size melted with about an equal proportion of water is added, till the colour is about the consistency of cream, and when chilled it is fit for use.

Commencing with the more simple papers, the first process is that of laying the grounds; to do this, the paper being placed on a bench about twelve feet long, the workman with two large brushes filled with colour, one in each hand, passes them over the paper with a circular motion, and as each piece is completed it is supported and carried by the attending boy on a stick, and placed on the rack to dry.

An ingenious machine has lately been invented, in which by three brushes acting, one with the other, the grounds are completely and evenly coloured, and in a much more expeditious manner than by hand.

The grounds being prepared, we will proceed with the printing, which is performed by means of blocks. They are carved most generally in pear tree, mounted on white deal; the design being first traced on the wood, the engraver or cutter, taking care to follow the exact outline, cuts perpendicularly to the depth of one-eighth of an inch, and then slopes off till he gets to the deal. I should add that where very sharp lines or dots are required metal is inserted in the block.

The colour with which the printing is to be performed, being mixed to the proper tint, is spread with a brush on what is called the sieve—a wooden frame covered with a blanket—the block is pressed on this and then applied to the paper, on which it leaves the impression of the design. There is a method of printing by a patent machine, invented by Messrs. Archer and Taverner, whereby, by placing the blocks on the sieve and then on the paper is performed with great exactness, with the labour of merely turning a lever handle, which is done by a boy. It was found, however, too cumbrous to move.

In the first case the pattern is given to the paper by a single block, but as in the second, where there are two shades of colour, two blocks are necessary. Now in order that the second block may be placed exactly in its proper situation, you perceive that there are pin marks in each block corresponding with each other, and on the marks printed by the first block the pins of the second block are placed, and the pattern is thus completed with the required correctness.

In another case a very delicate and shaded effect is given by a single impression, which is produced by what is called pin-work on a cylinder.

The pattern is formed by small brass pins of various sizes, fixed on a wooden cylinder at different spaces, according to the depth of shade required. This, fixed in a machine, is made to revolve so as to be supplied with colour from a blanket, and at the same time print the piece of paper very speedily without any interruption. This process, only lately applied to paperstaining, is derived from one much resembling it, in use in calico printing, only that the latter so far differs that the colour is contained inside the cylinder, and the pattern represented by holes pierced in it instead of pins fixed on it.

In other cases the pattern is worked on what is called a blended ground; this is also a modern invention, originating, I believe, in France. The blending is performed by a machine purposely constructed. A metal trough, the length of the breadth of paper, containing about twenty divisions, has in those divisions various tints of colour, according to the blending required; a long narrow brush is then dipped into the trough, and being filled with colour, applies it to a roller, from which it is collected by a large cylindrical brush the same length, which is made to revolve, and when it is properly supplied with colour it is then brought to bear upon the paper, on which it thus places the grounds, though in order to make it sufficiently perfect it is necessary to be done twice.

A common marble paper is printed by blocks in the ordinary way, and afterwards varnished with turpentine varnish, by which process it is enabled to bear washing, water not injuring it.

There is an improved imitation marble paper, made by Archer and Taverner, in which, if assisted by a few veins laid in by hand, the effect is certainly much superior to the last. The operation is considered secret, but it is easy to be perceived that the mode of making it nearly resembles that employed by the makers of the bookbinders' marble paper in which thickly gummed colours are made to float on the surface of water, and being stirred in various forms, are thus absorbed by the paper when applied to them.

In an imitation of wainscot the ground is combed as in the usual painted imitations of this wood, and the veins are afterwards printed.

The satin ground paper is a great improvement on the common grounds, and enables the manufacturer to produce imitations of silks and satins, which have a very elegant appearance. I have made every exertion to discover the date of the introduction of this improvement, but unfortunately without success. The oldest in the trade have never heard of it as a recent invention.

The satin ground is laid with satin white, a compound formed of lime and alum, and it can be coloured to almost any tint. After being laid like the common grounds, powdered French chalk is rubbed on it with a hard brush till the gloss is produced, and it is then glazed with clear size.

A process has been invented in England within the last five or six years which adds materially the beauty of the satin grounds; this is embossing, where imitations of watered and figured silks, stamped leather, &c., are produced. The embossing is performed by the paper being passed between two rollers, on one of which is the engraved pattern, and which also being slightly heated thus stamps the required design on the paper.

A kind of paperhanging in which the English designers seem to excel is called chintz, and has been introduced in imitation of the printed cottons and muslins, which seem to have been copied from Indian designs. There are in general several colours in these patterns, requiring many blocks and much delicacy in execution, though the number of blocks is sometimes much lessened by printing wash colours; such as yellow on blue making green, yellow on red orange, and lake on blue purple.

A manufacture of Archer and Taverner is one of the most creditable attempts in modern English paperstaining. It is an imitation of Chinese paper, and is composed of eighteen sets of blocks, each set containing four, altogether seventy-two blocks. It will be perceived that the flowers in that paper are shaded, which is effected by a process resembling that employed in blending the grounds. The long narrow brush is dipped in the trough containing the proper tints of colour and spreads these on the sieve. The block with the flowers engraved on it is then applied to the sieve thus arranged in shades, and afterwards prints the flowers in the tints, which are blended. This is a modern invention, first practised about five years ago by the Messrs. Harwood, the oldest firm at present in the trade.

Another important mechanical contrivance was invented about twenty years ago, whereby striped papers are executed with great exactness and clearness by a machine in lieu of blocks, which owing to the working always made an imperfect line. In this machine a copper trough, in which narrow slits of the required breadth are cut at the bottom, being filled with this colour, is applied to the paper, which is made to pass over a revolving cylinder, and draws the colours through the slits in the trough, by which the stripes are formed.

The ground of another specimen is crimson, and is laid with a staining colour instead of distemper. This colour, prepared principally from cochineal, is applied to the paper in the form of a wash, and is generally laid six times to produce a fine stain, the first coat being done with gamboge. In working the pattern it is printed before the staining is done, and thus acquires a much greater richness of colour.

The next example is a flock paper, a kind of hanging originally introduced as an imitation of the wove tapestries and velvet damasks. It has been employed in England more than 200 years, but about sixty years ago the art was almost lost, and only revived forty years since. The mode of working is very simple, although much mystery used to be observed respecting it. Flock is composed of the cuttings of white or bleached woollen cloth cut up in a mill to the necessary degree of fineness, and then dyed to various tints of colours. It is applied to the paper in the following manner:—The ground being prepared, the design is first printed with the block in size, in order that the oil may bear out when applied; when this is dry it is then printed with a composition of boiled oil and japan gold size, and while this is still wet the paper is laid on the drum (a kind of box about five feet by three feet, with the sides of wood and the bottom of ticking); the flock is then sprinkled over the paper, and the workman, with a cane, beats the under side of the drum, which causes the flock to spread evenly over every part of the pattern, to which it is fixed by means of the japan composition. Sometimes one flock is applied over another, this is easily accomplished by merely repeating the process after the first flock is perfectly dry.

In the next specimen a beautiful imitation of tapestry is produced by the introduction of flocks of various colours, and is done exactly as in the former examples, each flock being separately printed after the former ones are properly hardened and set.

I now take up the last of the three kinds of paperhangings, wherein metals are employed to produce imitations of gilt leather, rich brocades, or lightly etched ornaments. It is to these papers that our manufacturers seem now to devote their chief attention, and they work them with great beauty and richness, at a comparatively moderate price. I stated in my former paper that the gilt leather was employed in England even in the time of Henry VIII., and that the English were afterwards famed for its manufacture. I have every reason to suppose that gold and silver and metal leaf were introduced in the early paperhangings as an imitation of the more expensive leatherhanging, although I have not been able to discover the exact date of their first application. In addition to these there is another material of much more recent introduction, called bronze or imitation gold dust, which is now very extensively employed. This bronze is the invention of an artist at Nuremberg, named John Halitsch, who was born in 1595 and died in 1670, and his descendants have continued the manufacture to the present time. It is prepared by sifting the filings of different metals, washing them in a strong lye, and then placing them on a plate of iron or copper over a strong fire, where they are continually stirred till the colour is altered. Those of tin acquire by this process shades of gold colour, copper, red, and flame colours; iron and steel, blue and violet; and tin and bismuth, shades of a bluish white. The dust tinged in this manner is then put through a flatting mill.

A bronze paper is thus worked:—The design (as with flock) is first stamped with size, and afterwards with boiled oil and japan gold size; this preparation is allowed to dry, but while it still retains a tack the bronze is brushed over it with a hare's foot or soft brush; it thus adheres to the gold size, and the paper is in the state exhibited.

In another paper a much more splendid effect is produced by a metal, in imitation of gold leaf. A gold size, resembling that for bronze, is first applied, and while it has a tack the metal leaf is laid on. This metal, sometimes called mosaic gold or Dutch metal, is prepared in Germany, and is an amalgam of tin and copper. The effect of it on the paper is very much improved by embossing.

When coloured flocks are united with the metal pattern very splendid hangings are produced. The metal, too, is sometimes shaded, which is done by stains formed from berries, of which various kinds are used; and metal is also applied on a bronze ground, but the process is simply that already described. I need not add that in all cases where the metal is employed gold leaf may be substituted, but it is rarely used on account of the great increase in price. I have not described the washable paperhangings, or Delarue's patent paperhangings, because they are similar to those of which I have already spoken, with the exception that they are worked with japan gold size and turpentine instead of distemper, and the latter by being embossed in horizontal lines forms, by embossing alone, a pattern similar to that produced by printing.

I have made particular enquiries as to how the manufacture of paperhangings is conducted in France. I have visited the factories, and have the pleasure of being acquainted with the most eminent manufacturer at Paris, Monsieur Dauptain, and from all I can learn I do not find that the French employ other means than those known to us. In those papers of such large dimensions they have double sets of blocks, and in the decorative papers the mode of working is the same as our own; look, in fact, at what was done by our English manufacturers, Echardt and Sherringham, fifty years since; their works equal those of the French at the present day. Whence then arises our inferiority in this art? for that we are inferior all must confess. In the first place our manufacturers complain that, supposing they go to a great expense for an ornamental design it is liable to be pirated with impunity; and they say that were they protected by a patent right they should be able to bring out designs of much greater extent and perfection. This act of justice, I trust, will soon be granted to them; but even supposing this, I much fear we should still be behind our neighbours. In Paris the workmen have a better eye for colour than ours, they acquire, as it were, an imperceptible education in taste from the splendid works so continually before them; yet not depending on that alone the principal manufacturers there, constantly retain able artists, who, besides drawing the designs, arrange the tints and direct the working. Here, the task of the French artist falls to the hands of a mechanic, who, however able he may be as a workman, is still ignorant as an artist. What is the result?—the present mortifying comparison—can we now produce papers in which the flowers are so delicately tinted—can we arrange colours with the same science and harmony displayed? I repeat that though the French manufacturers use the same simple machinery, yet that their productions are far beyond our own—each tint, each shade of the numerous colours exhibited in the arabesques are stamped by a separate block. The expense of getting up these decorations is of course considerable, but instead of every year bringing out as we do, some fifty patterns, they are content to produce, perhaps, only one, or two, or three, each of which will always attract by the beauty and taste displayed. What I now write, I have often said to our manufacturers themselves, and some of them have replied; supposing no other obstacle, where can we get artists of the class to draw for us the designs you speak of? And here indeed is the difficulty—at present an insuperable difficulty, for, truly, there is not at this time in this country a class of decorative artists available for the paper-stainers. Those of any talent are so very few that they demand too high a price for the manufacturer. And yet of what consequence is it, not only in this, but in other manufactures, such as printed cottons, wools, figured silks, china, ornamental metal work, that we keep pace with other nations in regard to the taste displayed in these productions. How did the spirit and enterprise of Wedgwood raise the manufacture of porcelain in this country; where before his time we imported even for our own use—he caused his productions to be esteemed in all the countries of the globe for the elegance of their forms and the beauty of the designs which adorned them, and thus has enabled the manufacture to be carried to an extent never before anticipated. There are not many Wedgwoods. How trifling is the encouragement extended to our decorative artists, both for the true and proper education in their art and their employment afterwards! In any of the new palaces, in any of the modern grand national monuments, even in the national gallery itself, is there introduced any specimen of historical, allegorical, or decorative painting? Look at France, the new galleries of Versailles, where every room is decorated, the Bourse of Paris, the Madeleine. Look at Berlin—look at Munich. There the art is encouraged, the artists numerous. and their productions esteemed. It appears presumption in one so humble as myself to address thus the Institute of British Architects, but yet with them in a certain degree must rest the remedy. It is in your power to introduce in your designs the sister art of Painting. By encouraging that, the evils of which I complain would soon disappear—working schools, the only effective ones, would thus be formed, and besides adorning our buildings, you would be the means of more widely diffusing and perfecting a department, which, I think, all will agree is of such vital consequence to the character and importance of our national buildings, and to the success and well-being of our manufactures.

LUBRICATION.

(From Dr. Ure's Dictionary of Arts, Manufactures, and Mines.)

The following simple and efficacious plan of lubricating the joints and bearings of machinery by capillary attraction, has been kindly communicated to me by its ingenious inventor, Edward Woolsey, Esq. :—

Fig. 1. Fig. 2. Fig. 3.

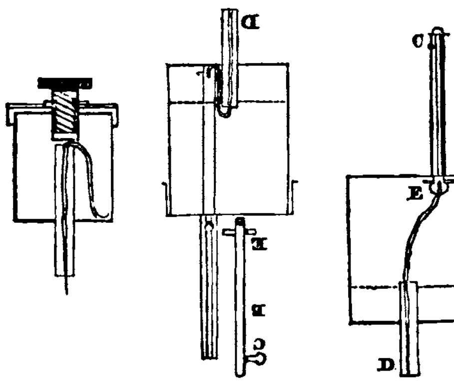


Figure 1 is a section of a tin cup, which has a small tin tube A, which passes through the bottom, as shown by the dotted lines. Oil is poured into the cup, and one end of a worsted or cotton thread is dipped into the oil, and the other end passed through the tube. The capillary attraction causes the oil to ascend and pass over the orifice of the tube, whence it gradually descends, and drops slower or quicker, according to the length of the thread, or its thickness, until every particle of oil is drawn over by this capillary syphon. The tube is intended to be put into the bearings of shafts, &c., and is made of any size that may be wished. If oil, or other liquids, is desired to be dropped upon a grindstone or other surface, this cup can have a handle to it, or be hung from the ceiling. It is frequently required to stop the capillary action when the machinery is not going; and this has been effected by means of a tightening screw, which passes through a screw boss in the cover of the cup, and presses against the internal orifice of the tube, preventing the oil from passing. As I find when these screw-cups are used upon beams of engines and moving bearings, that the screw is apt to be tightened by the motion; and also, as I think the action of the screw is uncertain, from the workman neglecting to screw it down sufficiently, it answers best to take out the capillary thread when the lubrication is not required; and to effect this easily, I have a tin top to the cup, with a round pipe soldered to it; this pipe has a slit in it, like a pencil case, and allows a bolt B to slide easily in it. In figure 2 the bolt is down; in figure 3, the bolt, which is a piece of brass wire, is drawn up, and there is no capillary action between the thread and the oil. In figure 3 it will be observed, that the bolt is kept in its place by its head C, resting in a lateral slit in the pipe, and it cannot be drawn out on account of the pin E. One end of the thread is fastened to the eye-hole at the bottom of the bolt, and the other end is tied to a small wire which crosses the lower orifice of the tube at D. By this simple contrivance the capillary action can be stopped or renewed in a second, without removing the top of the lubricator.

The saving by this plan, instead of pouring oil into the bearings, is 2 gallons out of 3, while the bearings are better oiled.

When you wish to see the quantity of oil remaining in the lubricator, the bolt must be dropped as in figure 2, and you can then lift the cover a little way off, without breaking the thread, and replenish with oil. The cost of figure 2, in tin plate is 9d. The figures in the wood-cuts are one-third of the full size.

CALEDONIAN CANAL.

We are heartily glad to see that a committee of the House of Commons has been appointed on a subject so important to Scotland, and to the commercial interests of the kingdom, as the improvement and completion of the Caledonian Canal. The report of Mr. Walker, to which allusion has been made, is an elaborate and valuable document. Mr. W. inspected the works of the canal by order of the Treasury, in consequence of some suggestions and statements made by Mr. May, the resident engineer and superintendent. After a careful survey, Mr. Walker was convinced that an extensive plan of repair and improvement was necessary, to give the undertaking *a fair chance*, and to carry out the original design of the late Mr. Telford. That design was worthy the genius and the fame of our distinguished countryman, but he was thwarted and confined by what now appears to have been a misplaced economy, and by that "ignorant impatience of taxation" (as Lord Londonderry used to term it) which manifested itself so strongly after the close of the late war. The government of the day was forced to yield to the reiterated opposition which was experienced in Parliament, and it was with the utmost difficulty that means could be obtained for putting the canal in such a state as to admit of its being opened for the imperfect accommodation of that small class of vessels to which the trade has hitherto been confined. [illegible] same niggardly parsimony, the works were hurried over in a super[illegible] and perhaps careless manner, the result of which now appears in premature dilapidation, and in frequent obstructions, even to the present limited traffic. Mr. Walker proposes to increase the available depth of water to seventeen feet. This is short of what was designed by Mr. Telford, but is amply sufficient for the accommodation of all descriptions of commercial trading vessels. He also proposes (what has been often recommended in our columns) the establishment of steam-tugs, on the lakes and estuaries, by which the passage would be rendered certain and expeditious under every condition of the weather. Vessels would thus be enabled to pass from one side of the kingdom to the other in two or three days. If we consider the immense and daily-increasing traffic which takes place between these extremities, such a facility of communication must be reckoned an important national benefit.

The leading object of the Caledonian Canal is, briefly, to save in the communication between the opposite parts of the kingdom, the present circuitous and dangerous passage by the Pentland Frith and Land's-end, on both of which the most serious delays and losses are well known to occur. This range of internal navigation includes on one hand the intercourse of the eastern ports of England and Scotland with America; and on the other hand it embraces the traffic of the western ports with the Baltic and the east of Europe. A similar object is attempted by the Forth and Clyde Canal, on which the trade is very extensive, but only for small vessels, and these subject to heavy rates. Yet high as the rates are, they are not considered an obstacle when compared with the safety and certainty of the passage, for vessels not exceeding eighty or a hundred tons burden. Now, it is precisely to extend the same advantages to *all classes* of maritime traders that we desire to see the Caledonian Canal completed. Mr. Walker calculates that in order to accomplish these objects effectually an expenditure of nearly 150,000*l.* would be necessary. This is a large sum, but it must be remembered that the works absolutely require repair, and the completion of the design would be attended with great and permanent public benefits. Indeed, the money already laid out must be considered as entirely thrown away, if the objects which the canal was designed to secure be not realised to the public. It is like building a house without roofing it in: however magnificent be the outline—however excellent the original plan—the superstructure is useless, and must crumble to decay. Another important consideration is adverted to by Mr. Walker: from the extensive changes in the physical condition of the valley, caused by the construction of a canal of so unprecedented a magnitude, and its connection with the extensive inland lakes, it would be attended with nearly as great an expense to shut the canal as to complete it! It would be necessary, in fact, to undo almost all that has been done. "Dams and outlets," says Mr. Walker, "would have to be made, permanent bridges to be built, the locks filled up or fenced, other works done, and compensations to be made which it is extremely difficult to calculate, and which might equal in amount the expense of a proper repair"—and all this independent of the public inconvenience, the cessation of intercourse and traffic in the west Highlands, and the breach of faith which such a proceeding would involve. Mr. Walker adduces various reasons in support of his decided opinion that the canal, if properly finished and supplied with the requisite facilities, would realise all that its most sanguine supporters have anticipated. One of these illustrations is to be found in the case of the Forth and Clyde Canal, of which the expense also far exceeded the original estimates, and which for thirty years remained in that unfinished and unserviceable state in which the Caledonian Canal is at present, until a public loan of 50,000*l.* was eventually obtained, by means of which it was completed and brought into beneficial operation. This sum has long been repaid with interest, and the undertaking has proved one of the most profitable concerns in the kingdom. May we not fairly hope for the same result in the case of the Caledonian Canal? Mr. Walker expresses himself with the utmost confidence on this head, and we agree with him in the favourable opinion he entertains of what the canal is likely to be at a future period. It has never been placed in a condition to insure success—it has not had even a chance—and all its bearings and prospects are completely altered by the introduction of steam. "The evidence given previous to its formation, and much less its workings since it was opened," says Mr. Walker, "have but little to do with its present prospect"—an opinion so reasonable in itself and backed by the high professional character of Mr. Walker, that it must have considerable effect on the committee, and on the nation at large. We shall rejoice to witness the full completion of a design so honourable to the country, and to the eminent engineer by whom it was planned, and so likely to be fraught with permanent national advantage.—*Inverness Courier.*

The Treffry Viaduct.—On Wednesday, the 6th ultimo, the first stone was laid of the intended viaduct, which is to cross Rocks' Mill Valley, it was performed by J. T. Treffry, Esq., in the presence of a large and highly respectable company. The viaduct is for the purpose of carrying a line of railway across the valley from the termination of the Par canal, (which canal is about three miles long from Par breakwater,) to Roche, a distance of about seven miles; and the whole is undertaken at the sole expense of Mr. Treffry, whose public-spirited exertions in works of utility to the county at an extraordinary outlay of private wealth and individual sacrifice, are the theme of every one's praise and admiration. This viaduct will extend across Rocks' Mill Valley, in the parishes of Lanlivery and Luxulian. Its length is to be 640 feet between the abutments, and it will consist of 10 arches, the span of each of which will be 40 feet. The height from the foundation will be about [illegible] feet, and the width of the base of the piers will be 26 by 10 feet 6 inches. The top of the viaduct will be 10 feet wide; and the whole, when complete, will present a very beautiful appearance, and be a great relief to the otherwise rugged but exceedingly picturesque and romantic valley which it is intended to cross.—Mr. Pease is the engineer, and Messrs. Bennett and Rowe are the contractors.

REVIEWS.

A Letter to Lord Viscount Melbourne on the Rebuilding of the Royal Exchange. By Thomas Hopper, Architect. London: Weale, 1839.

Professing to be upon the rebuilding of the Royal Exchange, this pamphlet bears quite as much upon the Post-Office, or, in fact, the latter is the principal subject, being that which is here illustrated by five plates, wherein the present edifice erected by Sir R. Smirke, and Mr. Hopper's competition design for it are compared together, for the purpose of showing how matters were managed on that occasion.

Respecting competition generally, the writer says: "No modern work stands sufficiently high in public estimation to warrant the appointment of any architect from his previous works, and competitions have been so unfortunately conducted as to raise a strong feeling against them; and yet, that seems the most reasonable way of proceeding, if sufficient precaution were used to prevent intrigue and jobbing."

Now, in regard to intrigue and jobbing, we are of opinion they might be effectually prevented, at least rendered almost next to impossible, by adopting a properly devised system—the chief difficulty is how to enforce such a system; or, we may be wrong in calling that the chief difficulty, when another most perplexing one remains, not to be got over by all the fairness in the world; for, supposing every thing to be conducted in the most open and honourable manner, without either the slightest wish to show favour to any one, or the possibility of doing so, still with the very best intentions, and the determination to choose entirely according to merit, the selection must depend upon the taste and judgment of the umpires. So far there is a very great chance of error after all; nor will there be any remedy for it, until architecture itself shall become, a branch of the fine arts, which is a very different thing from its being taken up as a professional pursuit, one of the studies included in a gentleman's education. Then, and not till then, can architecture be properly encouraged, because, not till then, can talent manifested in it, be appreciated by a sufficient number whose voices can be admitted as those of a public competent to express their opinion, and to decide between merit and mere pretension. In the mean while, and the sooner a beginning is made the better, something may be done towards establishing a fairer and more effectual system of competition. Perhaps, were the following regulations adopted, the evil now complained of would be in a great measure removed:—First, it should be imperative that all the designs should be drawn to one scale, and merely shaded; and that all perspective views accompanying them should be taken from the same station or stations. Next, that in case of models, all should likewise be made to one scale, and each accompanied with a perspective view, showing what would be its appearance when executed, and seen in combination with the buildings or other objects belonging to the proposed site; because in themselves models are most fallacious, and moreover captivate and delude the eye by a certain *prettiness* that would not belong to the buildings erected from them. Next, it should be made an invariable rule that the designs should be publicly exhibited BEFORE any one be selected, or any premiums awarded. This would save an immense deal of trouble to the Selecting Committee, inasmuch as they would be able to compare the designs more leisurely, and also have the benefit of learning public opinion in regard to them; not that they need, therefore, be absolutely dictated to by that, should they have sufficient reasons for dissenting from it. This parliamentary ordeal being gone through, the next step would be to select a certain number of designs of the greatest mark and likelihood, and closely investigate their merits, throwing out from time to time such as appeared less eligible, until only two or three remained for final choice and decision, after diligent inquiry into their respective claims. Nor ought such decision to be reported to the public merely in its result, but the votes—Ayes and Noes—ought to be specifically recorded; since each individual would then feel himself responsible for his own opinion, while another advantage would be that incompetent persons would be rather more shy than at present of putting themselves upon such committees, more especially if each member were compelled to allege his reasons for his decision, in writing.

Like many other excellent schemes, this of ours may be too Utopian to be adopted, neither do we recommend it with any such expectation, but simply with the view of showing, that, were there a sincere disposition to manage such matters fairly and honourably, and not only honourably, but without even any suspicion of intrigue, it would not be quite so difficult to devise an effective system as is now generally imagined. The public exhibition of the designs for the Nelson Monument, by showing the utility of affording the public an opportunity of expressing their opinion, while it can be offered in the shape of remonstrance instead of unavailing reproach is a case in point. Another, and not the least advantage which might fairly be anticipated from the system above recommended, is that incompetent persons would be deterred from entering into competition, being tolerably aware that there would be little chance of success for them, were it made an inviolable rule to exhibit all the designs publicly beforehand; or even of any notice, except for their decided inferiority. On the other hand, it would operate as a stimulus to men of talent, because, whether ultimately successful or not, they might distinguish themselves with *éclat*, and obtain numerous suffrages from the public.

But we seem almost to have forgotten Mr. Hopper; therefore let us now resume, by saying that he holds up as a warning the proceedings connected with the competition for the Post-Office, for which building he himself sent in a design. Wherefore he should now for the first time bring that matter thus publicly forward, is easily explained. In fact, the secret belonging to it has been recently divulged by no other than Mr. Sidney Smirke, the architect's brother, and the author of the account of the Post-Office, in Leeds's new edition of the Illustrations of the Public Buildings of London, where it forms one of the new subjects, and the only one of them not described by the editor himself. In that account Mr. S. Smirke has very incautiously made a disclosure, that while it shows how unfairly all the competitors were treated, reflects no very great credit on Sir Robert himself, because, we are informed that he did not gain the preference by any superiority of talent he had manifested; but, none of the designs sent in being found exactly suitable, "to relieve themselves from this embarrassment the Lords of the Treasury commissioned Sir Robert (then Mr.) Smirke, who had not himself hitherto entered into the field, to make himself thoroughly acquainted with the business of the Post-Office, and to make the experience so acquired the foundation of a plan for the new building." Coming from such source the truth of this admits of no doubt, but it is a most extraordinary instance of sincerity. We certainly do not mean to insinuate that Sir Robert himself was reprehensible on that occasion, but it is clear enough that he was favoured to injury of others; since, surely if a fresh design was absolutely requisite, the proper course would have been to have commissioned the author of the best one that had been sent in, "to make *himself* thoroughly acquainted with the business of the Post-Office;" and then, either modifying his first plans accordingly, or else laying them aside, to prepare an entirely new design.

Whether accidental or not, there is certainly a strong general resemblance between Mr. Hopper's façade and the one erected. The order is the same, and the chief difference is that the former has a much greater number of columns, the portico being octastyle, the end pavilions hexastyle, and the intermediate parts decorated with half columns; the pavilions also form porticos, with an entrance in each of them. Still, as regards the centre portico, we prefer the one executed, because no windows are introduced into it; but, as to the respective plans, we think that more might have been made of Mr. Hopper's, where a wide central corridor runs through the centre of the building from wing to wing transversely, to the great hall, in passing through which a fine architectural vista would have presented itself on each side, provided, that avenue (upwards of 300 feet long) had been suitably embellished and the light thrown down from above at each extremity of it.

We presume that the other elevation by Mr. Hopper, here published "in the style of a favourite design," is intended, whether satirically or not, to allude to Mr. Barry's design for the terrace-front of the new houses of Parliament.

The London and Birmingham Railway. By Thomas Roscoe, Esq. assisted by Peter Lecount, Esq., F.R.A.S., Civil Engineer; *with a Map of the Line, 18 fine steel plates, and numerous wood engravings.* London: Charles Tilt. Birmingham: Wrightson and Webb.

We have several times made extracts from this very interesting work, which is of that sterling character that it may be read with pleasure either by the professional or general reader. The description of the immense works carried on during the progress of the railway shows the vast expense, great outlay, and antagonist difficulties with which railway companies have had to contend from the first projection of the company to the conclusion of the work. It also shows with what great perseverance it was necessary to combat the bigoted prejudices of various parties, some even interested in the progress of railways. We have read the work with considerable pleasure, and doubt not that it will be perused by our subscribers with equal interest, while, to give a specimen of the general character of the volume, we shall occasionally give a few more extracts.

The plates and wood engravings (we ought perhaps to have mentioned before) are particularly deserving of notice, as they illustrate the description and show some of the stupendous works on the railway, the map at the commencement, reduced from Cheffin's large official map, will be found particularly useful to the traveller. Before we dismiss the work we must call the attention of the reader to consider the vast talent and discrimination that has been bestowed on the works of the railway by the several resident engineers on the line; and it would afford us much pleasure if we could see on the various parts of the railway some tablet or inscription stating the names of the individuals to whom the works were intrusted by the engineer in chief, Robert Stephenson, Esq. To this engineer, however, no inscription is necessary, for the railway alone will be a sufficient monument to hand down to future ages the name of ROBERT STEPHENSON.

Roscoe's Book of the Grand Junction Railway, from Birmingham, Liverpool, and Manchester, with sixteen Engravings, and four Maps. London: Orr and Co.

During the progress of this work through the press, we have had occasion several times to speak of it, and its conclusion fully justifies what we have before said in its praise. The various engravings are beautifully executed, and present faithful representations of some of the principal works on the railway, together with views of the adjacent country. The letter press contains much useful and interesting information connected with the progress of the railway, and descriptions of the towns and villages in the vicinity of the line.

Certainly, however much authors may regret the destruction of the picturesque by railways, they must admit that these works have not been without some benefit to the literary world, for on the Birmingham road alone a hundred guide books must have been written, and some, as in this instance, uniting the highest resources of the sister arts.

Popular Instructions on the Calculations of Probabilities; translated from the French of M. A. Quetelet, by R. BEAMISH, Esq., C.E., F.R.S., &c. London: Weale, 1839.

The doctrine of probabilities is one which has for a long period occupied the attention of philosophers, and the work of M. Quetelet is the latest, and at the same time, one which assumes the merit of a popular form. M. Quetelet has certainly not shown a very great power in effecting his object, and from the skill displayed by Mr. Beamish, we should have preferred an original work to this translation. Indeed the whole work wants a recast to adapt it to English habits and English social progress, and in its present state while some parts seem redundant, others require explanation. Mr. Beamish leaves several things to be wished for with regard to style, and there are many points which he has left unelucidated, where a simple note would have cleared up the subject. It ought to be explained that a pack of cards on the continent, as for piquet in England, consists of 32, rejecting all cards under the seven except the ace. The questions at the end of each chapter are a superannuated process which had better be dismissed; the first and second chapters are too diffuse; in the treatise on lotteries Geneva is confounded with Genoa: and the chapter on assurances is almost inapplicable to this country, as is that on the decisions of tribunals, where we have no judges of facts.

Mr. Beamish has in the notes exhibited an ability which we should have liked to have seen better employed than as a satellite to M. Quetelet, and indeed his labours confer on the work a value independent of its original merits. The bearings of the law of probabilities on hypothesis is an important department of mathematical philosophy, and one which no one engaged in study or investigations should neglect, while in this small volume may be found useful information delivered in a clear and plain manner, which, while it cannot fail to be beneficial to all classes, to most readers must be highly valuable.

The Year Book of Facts in Science and Art. By the Editor of the "Arcana of Science." London: Simpkin and Marshall, 1839.

The Editor of this work had in the course of his labours on the "Arcana of Science," the opportunity of acquiring an experience, which he has happily devoted to carrying out the same plan on a more extensive scale. In the small space of this duodecimo the onward progress of science and art is chronicled, and both the practical and theoretical student can appreciate how far the wheels of the triumphant car have been driven in their successful course. The new inventions in mechanics, and the useful and speculative arts are registered from the most authentic sources, and we feel happy to see that we ourselves have been able to contribute in some degree to the general store. The editor has long laboured in the school of cheap and good literature, and he has in this instance produced a work worthy of his former exertions, and propitious to his future career.

Theory, Practice, and Architecture of Bridges. The Theory by JAMES HANN, of King's College; and *the Practical and Architectural Treatise by* WILLIAM HOSKING, F.S.A., &c. London: John Weale, 1839. Part 1.

From the specimen number before us, this promises to be an invaluable work, and one that was much wanting. It is surprising that England, which can boast of having the grandest bridges in the world, has not a single treatise on their construction. We regret that we have not space in the present number to enter into the character of the work, but in our next will enter into it more fully, by which time we hope to see one or two more parts published. The first part contains an admirable engraving of George Stephenson, besides three outline engravings of an American timber bridge; a bridge over the Calder and Hebble navigation; three plates of the Wellington Dean viaduct bridge; two of the Ouse-burn viaduct; one of the Victoria bridge on the Durham junction railway; and a bridge on the London and Croydon railway. We must impress on the attention of both the editors and the publisher, the necessity of giving full specifications and estimates of the bridges as far as possible, for to the profession they will form the most valuable part of the work. The unusually low price at which each part is published, and the excellency of the engravings, must ensure it a large sale, which there appears every endeavour on he part of the publisher to merit and obtain.

Illustration of Mechanics. By the Rev. H. MOSELEY, M.A., F.R.S., &c. London: Longman and Co., 1839.

We hail with pleasure the first volume of a series of "Illustrations of Science, by Professors of King's College, London." Such works will do more to enlighten the student than any works with which we are acquainted; they will form invaluable references and assistance to those who may attend the lectures of the professors. In our next Journal we shall enter into a more minute enquiry into these works, and the system of education adopted in the class of Civil Engineering at the college.

Observations upon the Report of the Irish Railway Commissioners. By GEORGE LEWIS SMYTH. London: Hooper, 1839.

This is a most able summary of all the arguments on the moral and political bearings of this nefarious job. Mr. Smith fully proves that the government, from all past experience, is totally incompetent for such a trust, and that, even if they were, that their interference has been attended with the most fatal results to the Irish people, inducing a blind dependence on the government, and deadening all their enterprize and exertions.

The subject is treated clearly and efficiently, and there is such a collection of documentary evidence as might even convince one of the principal jobationers. We are happy to hail the co-operation of Mr. Smyth, and cannot but express our sentiments of the service which this work is calculated to do in exposing that ridiculous abortion of selfish interests and public jobbers.

LITERARY NOTICES.

We have reserved our notice of Mr. Hay's work *On Colour* until our next number.

The Popular Lecturer is the title of a periodical published by Paul, which for the price of a penny weekly, gives lectures delivered at the different institutions by men of eminence. The parts before us contain lectures by Messrs. Bowring, Birkbeck, Col. Thompson, Grainger, &c, and the subjects are illustrated with numerous wood-cuts. Like a buoy floating on the sea, this publication shows the state of things below the surface, and is an excellent omen of the progress of literary institutions in the metropolis, and of the manner in which they are diffusing popular information.

The Sepulchral Monuments, by Carl Tottie, we noticed individually on the appearance of the first parts, and those since received maintain the same character. The plates are beautifully engraved, and the designs are infinitely superior to anything of the same kind which has yet been presented to the public. Their merit is simplicity, but this we regret too often degenerates into nakedness; the artist is evidently deficient in a correct eye for proportion, leaving large spaces unrelieved, or when this fault is remedied, it is often by the introduction of some extraneous feature which is an equal disparagement to the design.

A Letter to the Shareholders in the Great Western Railway, by Edward Ryley, is an undigested pamphlet, from such sources as the Irish Railway Commission, and Wood and Hawkshaw's reports, brought forward a prop to Kollman's patent railway. The writer's motto, from Virgil, is *Tros Tyriusve mihi nullo discrimine agetur*, which, translated, signifies, "I care neither for Trojan or Tyrian, but for *egomet*,—I, by myself."

ARTESIAN WELLS.

[This subject is, once again, exciting a good deal of attention. The old schemes have been revived, for supplying considerable districts, indeed whole parishes, of this thirsty metropolis, with water, by sinking wells through the London clay. When the project was heretofore under discussion, we brought together such evidence as appeared to us conclusive against it. But as the importunate appealers to our breeches pockets are not easily to be got rid of, we thought, under these circumstances, that our readers might desire to hear the opinion of a geologist; and as Mr. Webster, who is at present delivering a course of lectures on Geology at the Russell Institution, fully considered the question last week, in a lecture on the tertiary formations, we present an abstract of so much as referred directly to this subject.]

Mr. Webster observed, that an Artesian well is produced by boring through strata impervious to water, down to another stratum containing water, and so placed that this fluid will rise up through the bore by hydrostatic pressure; that is, by the pressure of another part of the water on a higher level. He then pointed out what he considered to be the true source from whence the water found below the London clay is derived. We must first imagine a geat depression in the chalk stratum that covers the chief part of the south-east of England, the boundaries of which depression or basin is marked by the North Downs, Marlborough Downs, and the Chilton Downs, where the chalk is on the surface. Within this depression, we must, then, conceive a great stratum of sand, lying in the chalk, but less extensive,—or rather several strata of sand alternating with several beds of coarse pipe-clay, but in a very irregular manner. This bed is named the sand and plastic clay; and this sand contains a large quantity of water, so as to be, in some places, almost of the nature of quick sand. Over these last strata lies a very thick one of dark blue clay, called the London clay, which being less extensive still than the sand, leaves a portion of the latter exposed in a belt or outcrop all round the basin. Now when rain falls upon the chalk downs, it descends the slopes in streamlets towards the centre of the basin; and when it meets with the sand uncovered, it sinks into it, passing downwards below the London clay. In course of time, from this cause, the whole of the sand stratum has become full of water, and must continue to be so, except the latter should be drawn out; and it is evident that this water stratum can be exhausted only by raising out of it a quantity of water greater than the supply it receives from the hills all round. The rain which falls upon the London clay cannot add to the water beneath it, since this clay is impervious; and, therefore, landsprings only are found on the top. If a boring be made anywhere through the blue or London clay, down to the stratum of sand containing water, the latter will rise in the bore with considerable force, to the same height or level as the outcrop of sand between the London clay and the chalk. If this boring be made at a spot which is on a lower level than this source, the water will spout up like a fountain; but if the boring be made in a place where the surface of the ground is higher than the source, then the water, though it will rise, will not reach the surface · and this accounts for the various heights to which the water ascends in various Artesian wells. (We omit the description of the mineralogical characters of these strata, and of the fossils they contain, and confine ourselves to the circumstances connected with the water.) During the last twenty years, a great many perforations have been made through the London clay, from its having been found that simple boring with an auger is sufficient when a small supply only is required: and enough has been done, fully to establish the truth of the geological principle, that the sand stratum bearing water extends all under the London clay; and that the metropolis stands upon a chalk basin containing an immense quantity of pure soft water, sufficient for the supply of many breweries, and numerous private houses, &c. But now comes the question: is this pure soft water sufficient in quantity, not merely for the consumption just mentioned, but for the supply of the whole metropolis, or of several parishes, or of a single parish? With respect to the actual quantity of water in the basin, it is impossible to calculate it with any certainty; for although we can estimate the extent of the sand and water stratum from the map, yet we cannot ascertain its thickness, since this varies in different places. In by far the greater number of borings the thickness has not been taken account of, because the work generally ceases at the top of the sand, when water appears: to say nothing of the impossibility of knowing the proportions of water and sand. Mr. Webster went on to prove that the stratum of sand and water is extremely irregular, and that we cannot have a clear idea of its actual nature, except a much more accurate account of the borings were kept than had been the case. The sand stratum is subdivided, in all probability, by bands of clay: and it is incorrect to assert, as has been done, that it is possible to predict success in sinking in one place, because a successful boring has been made in another; or that the supply of water will be the same in all places. All mention has been omitted, when speculating on this project, of the well-known failure of many Artesian wells: and it is certain that, in several cases, one well has taken the water from another, proving that the supply in that locality was limited. Mr Webster next adverted to an experiment which had been made by the New River Company, in endeavouring to avail themselves of the water below the London clay, by sinking a large shaft or well at their reservoir in the Hampstead Road. At a depth of 170 feet they came to the stratum of sand and water, which rose up together, as is usual, into the well; but finding that they could not sufficiently separate the water from the sand, which is the chief difficulty in forming wells on a great scale in the London clay, they passed through this running or quicksand, by means of cast-iron cylinders, at an expense of 4,000*l*., independent of the 8,000*l*. which the well cost, hoping to obtain water by sinking into the chalk below. They found water in that stratum, but in quantity too inconsiderable for their object; and hence this well has been represented as a failure. Mr. Webster stated, that, considering this experiment as an important one, he applied to Mr. Mylne, engineer to the New River Company, for information respecting it, and received from him all the information he required. A remarkable discrepancy had appeared in the public statements respecting this well; on one side it having been termed a failure, whereas information was given to the vestry of St. Pancras by one of the workmen who had been employed, that water had been obtained at the rate of 6,350,400 gallons weekly; this Mr. Mylne explained by stating that the term *failure* had been used, not as implying that they had not got water, but that they had not procured it in sufficient quantity to answer their purpose as *matter of trade:* the actual quantity being only 650,000 gallons per week, instead of 6,350,400, less than one-ninth part of what had been reported! Mr. Mylne likewise stated that, so far was the supply from being constant, they were able to work the pump in raising the water only one-third of their time; because, when they had procured what water trickled in slowly through the chalk, they were obliged to wait until a sufficient quantity was again collected. Mr. Webster seemed to consider the idea of a certain supply of water in the chalk, independently of that in the sand stratum, as a fallacy, or at least extremely problematical; and that the water found there had proceeded from the sand stratum resting upon it, and which had forced its way downwards through numerous minute fissures in the chalk. He observed that the procuring much water at a number of points considerably distant from each other, by no means demonstrated, as had been asserted, the certainty of raising the same quantity by means of a single large well; and he further observed, that since it was a manifest and great advantage which the inhabitants of London now possessed, and which was unknown formerly, that they can have numerous supplies of fine spring water only by boring, it was well worth consideration whether the sinking large shafts, and employing powerful machinery to raise water, might not disturb the sand and water stratum to some distance, so as to destroy or injure the subterranean channels by which water reaches those wells, which are already the property of individuals; while at the same time no reliance can be placed on the continuance, without interruption, of a supply on so great a scale as is contemplated from this source. Upon the whole, Mr. Webster gave it as his opinion, that proper and sufficient data had not yet been collected, to establish, upon good authority, the existence of water in sufficient abundance to afford a constant supply to the metropolis, or even a considerable district, by raising it in a single place from below the London clay, notwithstanding borings or Artesian wells, dispersed through London, fulfil their object in furnishing manufactories and many private houses with water.

With respect to the present supply of water to the metropolis. Mr. Webster observed, that although the subject did not come properly within the scope of his lecture, he would just state, that a considerable degree of misapprehension still existed on the subject. The Thames water is often represented as of bad quality. There is no doubt, that in its progress through the capital, it is rendered very impure; but it has been abundantly proved by the accurate analysis of the most eminent chemists, that when the supply is taken sufficiently high up the river, and conducted into the town in a proper manner, it is of great purity. At present the parishes of Marylebone, St. George's, St. James's, are supplied from parts of the river much beyond the influence of the London drainage. Possessing this, and other excellent sources, we cannot be said to be unfavourably situated by nature respecting a necessary of life of the first importance.—*Athenæum.*

PROCEEDINGS OF SCIENTIFIC SOCIETIES.

INSTITUTION OF CIVIL ENGINEERS.

Feb. 12, 1839.—The PRESIDENT in the chair.

The following gentlemen were elected:—Robert Hawthorn, Nicholas Harvey, and William West, as Members; J. R. M'Clean, as a Graduate; E. W Brayley, as an Associate; and General Sir John F. Burgoyne, R. E., as an Honorary Member.

"On the Properties and Composition of the Peat and Resin Fuel." By C. Wye Williams, A. Inst. C. E.

The nature of the fuel being of great importance in the manufacture of iron and the arts generally, it is interesting to inquire into the value of peat for these purposes. Peat may also be used for railroad engines, and with peculiar advantage, being free from many of the impurities of gas cokes: it may also be used in combination with resin, or other bituminous substances, as a fuel for long voyages. The bogs of Ireland were, nearly thirty years ago, designated by a Mr. Griffiths as mines above ground; who remarked, also, that the iron founders in Dublin might probably, ere long, be supplied with turf-charcoal, which is superior to every other for their purpose. The attention of the author was directed to the use of peat for the steamers on the Shannon, where coal is necessarily dear, and peat was at first used only for economy; the impediments to its use, from its bulk and dampness, being great. The property of holding and absorbing moisture is also a great impediment to its use, particularly in wet seasons, the only remedy for which is great care during the process of drying and in its subsequent preparation, any care being amply repaid by the diminished consumption. The evils of its bulk and low specific gravity may be obviated by compressing it when dry; when compressed perfectly dry, and kept free from moisture, it will preserve its bulk. From some observations of Tredgold, respecting the earthy impurities and odour of peat when burnt, it is obvious that he experimented on peats from the lower strata; but the author, in opposition to several eminent philosophers, maintains that turf coke may be made more effective than wood charcoal. The author, in his first experiments, came to the same conclusions from using the lower though impurer strata, simply because they were the denser, and rejecting the lighter kinds. The lower strata sometimes contains peat of a tolerable purity, but generally the upper and lighter portions are superior in the purity of the carbon, the intensity and quality of its heat, to those portions which have acquired density by time and natural pressure. When the density is acquired by artificial pressure, we have a substance superior to any other for all purposes of metallurgy.

The difficulty in the conversion of turf into coke has hitherto lain in depriving it of its volatile substances so as to make a pure carbon, and in avoiding waste by partial combustion. This is effected by an union of the distillatory with the stifling process; the volatile substances are expelled in the oven, and when sufficiently charred the stifling process is adopted. Turf for the forge must have a greater density than that acquired by this process. This is effected by pulverising or bruising it, so as to destroy the fibrous character, and bring the component parts into closer and more permanent contact. By the union of these processes, any density may be given to the fuel which will combine the purity of vegetable charcoal with the density of mineral coke. The specific gravities of the turf hard pressed (water being 1000) is 1160—of the coke from the hard pressed 1040. Thus, the hard pressed turf is denser than the densest wood, and the turf coke double the density of charcoal and equal to coal coke.

The test adopted by the author, after Berthier, of the calorific power, or relative power of absorbing oxygen, is the quantity of metallic lead reduced from its state of oxide by giving weights of the several fuels. Pure carbon gives 340 grains, wood charcoal 307, turf coke 277, best coal coke 277.

Thus we have a measure of the relative quantities of heat; but intensity of heat is often of more consequence than quantity, and intensity depends on the density of the fuel. Berthier remarks that the superiority of coke to wood charcoal is owing to its density. In the above comparison, no account is taken of the impurities of the fuels; consequently, turf coke, being free of sulphur, has great advantages. The author finds that iron worked with turf coke is sooner brought to a welding heat, works softer, and comparatively free from scales.

The author then describes the resin fuel as an artificial coal produced by imitating the process of nature, in the best combinations peculiar to coal. Natural pit coal consists of bituminous, carbonaceous, and various foreign ingredients, of which sulphur is in abundance, and very injurious. The resin fuel consists of resin, the purest available bitumen, and turf coke, the purest vegetable carbon. Thus, the greatest heating power exists in the smallest bulk, and the excess of bitumen and deficiency of carbon, as in cannel coal, or excess of carbon and deficiency of bitumen, as in anthracite, may be avoided. Resin, notwithstanding its price, is used in steam navigation, but very disadvantageously, in combination with cinders, as it melts and passes off in a state of vapour, not entering readily into combustion with the oxygen of the atmosphere. But in the resin fuel, in consequence of the extraordinary attraction which subsists between carbon and oxygen, the resin has its full combustible and calorific effect. In the furnaces of boilers, a solid cinder is requisite, which may be produced by adding some of the inferior bitumen, as pitch and tar. The fuel is manufactured by adding turf coke, in a state of powder, to the bitumen in a melting state, and in such quantities as to saturate each other. The average price of the fuel is 30s. to 40s. per ton. Its use was fully tested in the voyages of the Royal William, in which 20 cwt. of coal, with 2 cwt. of the fuel, did the work of 26 cwt. of coal. The suddenness of the action and the great increase of heat for a small increase in its consumption, render it of great value in cases of emergency. The author concludes by expressing his conviction, after ten years' experience, that the turf bogs of Ireland may be rendered available for many important uses in the arts.

Feb. 19.—The President in the chair.

The following gentlemen were elected:—J. A. Galloway, as a Member; E. Birch, as a Graduate; G. Moore, C. Robinson, and S. Reed, as Associates; and Captain Sir E. Parry, as an Honorary Member.

"On Railways in America." Communicated in a letter to the President. By S. W. Roberts.

The writer describes the various methods which had been adopted of laying down Railways in America during the last twelve years. First, timber rails with light flat iron bars were tried; these were found cheap, but not durable. Next, stone rails, or sills similarly plated. Next, heavy iron rails laid on blocks of stone; the violent vicissitudes of the seasons soon deranged the foundation of these, and caused the track to spread. The heavy iron rails were next laid on a foundation of timber. The Alleghany Portage Railroad was laid four years ago by the writer with hewn white oak timber, 10 inches square, imbedded in the ground; upon these cross sills of locust timber, 6 by eight inches, and 7½ feet long, notched and trenailed. On the top of these cross sills, and directly over the longitudinal timbers, the cast-iron chairs which supported the rails were bolted. The track was thus effectually prevented from spreading. The rails are from 45 to 60 lbs. per yard, from 3 to 3¾ inches in height, and from 3½ to 4¼ inches on the base. On roads with difficult curves "bogie" engines are used. Each locomotive has six wheels. The hinder part is supported by a pair of driving wheels, 4 to 5 feet in diameter, and the front part rests upon a bolster on the bogie, which has four wheels of about 33 inches diameter. Each passenger car is 36 feet long and holds fifty persons, and warmed by a stove. The long cars are adopted as less likely to upset than those on six wheels. The average speed, including stoppages, is 15 miles per hour.

"Manchester and Leeds Railway Section." By Francis Whishaw, M. Inst. C. E.

This section, prepared under the direction of Mr. Whishaw, is designed to afford a novel and useful method of embodying a great mass of the details required by an engineer when giving evidence before a Parliamentary Committee. This section was constructed before the last standing orders, and the author had here anticipated them in putting upon this section much of the detail now required. By sections thus prepared the engineer can always answer any questions which may be put to him.

"Account of Boring for Water through Granite." By Frederick Holland. Communicated by Apsley Pellatt, A. Inst. C. E.

A hole, 6 feet wide and 7 feet deep, was first dug, and a wooden cylinder lined with bricks inserted. Two pieces of cast-iron pipe, 6 feet in length and 8 inches in diameter, turned smooth at both ends, and united by a wrought-iron hoop ring, so that when the whole number of pipes were driven, a continuous pipe, perfectly cylindrical, both on the inside and on the out, was formed. Nine lengths of pipe were connected and driven, and then the boring commenced, and continued through a hard rich species of rock or granite, having all the component parts but not the compactness of granite. The boring was continued to a depth of 175 feet. The supply has been regular at the rate of from 48 to 50 gallons per minute, a temperature of 48° F., the external air being 52½° F.

Mr. Brunel stated, that the advance of the Thames Tunnel was now at the rate of 3 feet per week; they were now 64 feet from low-water mark. He presented some specimens of sand, which, when mixed with a certain quantity of water, was exceedingly troublesome. They frequently push the poling boards before them: last night not less than 60 square feet was pushed before them. They fight their way on with difficulty, but continuously.

Feb. 26.—The President in the chair.

The following gentlemen were elected:—G. Grove, J. B. Redman, as Graduates; S. M. Peto, T. Grissell, and Rev. S. King, as Associates.

"On the Economy of working expansively in Crank Engines." By John Watt.

A letter from Mr. Watt was read on the economy produced by working steam in large steam engines expansively, in which the author details the result of some experiments on a high pressure engine, employed for blowing furnaces. The steam cylinder of the engine in question was 38 inches in diameter, the blowing cylinder 122 inches, length of stroke 9 feet, pressure on the piston 41 lbs., and in the boiler 45 lbs. per square inch, the number of strokes about 12 per minute, and the pillar of blast 2½. A large fly-wheel was attached, and on fitting the steam engine with an expansive apparatus and cutting off at half stroke, the performance was greater than at any previous time, with a saving of 25 per cent. of fuel. The author refers this to the fact, that all the moving parts, with the exception of the fly-wheel, are brought to a state of rest at the conclusion of each stroke, and that if the steam be allowed to enter throughout the whole length of the stroke, the piston will have to draw from the fly-wheel momentum sufficient to overcome its own momentum, and to alter the direction of its reciprocating parts; but the steam being cut off so that the momentum be destroyed by the time the piston terminates its stroke, the return stroke will be commenced without checking the unnecessary impetus which exists when the steam is admitted to the end of the stroke. Thus it is observed, that engines working expansively pass the centres more easily than when working full pressure throughout the stroke. The momentum which has to be destroyed is created at the expenditure of more than half a cylinder full of steam; and the checking this motion is also accompanied by a still further waste of steam. Mr. Watt had altered an engine driving rolls for rolling iron, and the result of cutting off at half stroke was here also attended with a saving of 25 per cent. of fuel.

March 5.—The President in the chair.

The following gentlemen were elected:—Thomas Chalmers, Andrew Burn, as Graduates; and John William Lubbock, as an Honorary Member.

"On the Comparison between the power of Locomotive Engines, and the effect produced by that power at different velocities." By Professor Barlow, Hon. M. Inst. C. E.

In this paper the author does not attempt to explain an exact method for computing the power of locomotive engines, but only one tolerably approximate. The method he pursues is this:—"If we know experimentally the number of cubic feet of water evaporated in any given time by an engine, the space passed over in that time, the length of stroke and the capacity of the cylinder, we hence know how many cubic feet of steam have been employed, and, consequently, the mean number of cubic feet of steam produced from one cubic foot of water: hence, again, by experiments that have been made by different writers upon the power of steam, we know the pressure per inch on the piston, and then making due allowance for the resistance of the atmosphere on the piston, the friction of the engine-gear, &c., we have left the force that ought to be effective. And this being reduced to the circumference of the wheel, it should be equal to the resistance opposed by the load, which, on a level plane, consists of axle friction, road resistance, and the resistance of the atmosphere to the engine and carriages. But this is assuming a perfect action to the engine without any waste, which, though much to be desired, is certainly seldom the case." The author then goes on to select some experiments from those made on the North Star and Harvey engines, as reported by Mr. Wood to the Directors of the Great Western Railway. He also gives such columns from Mr. Wood's Tables as are requisite, together with additional columns resulting from the computations above indicated. And after treating upon these at some length, he concludes his paper by making a few observations on the effect of gradients.

"The Description of a Floating Clough." By George Ellis, Associate Inst. C. E.

This machine was used for scouring a channel which leads from the Winestead Drainage and Haven of Patrington into the River Humber. It was constructed in the following manner:—The frame is made of timbers 6 inches by 4, 12 feet long, 9 wide, and 6 deep. This frame is covered with planking, two inches thick, and through the middle of it a culvert is formed, with planks 2 feet 6 inches in width, with a small lifting door at the end. Connected with the bottom and projecting in front are two long beams called feelers, which keep the machine in its course; at the bottom in front are frames of wood, shod with rough iron like the teeth of a saw, and these are connected with racks which can be raised by a lever. At each side of the machine there is a wing which is made to fit the slope of the banks, to dress the mud from the sides and to keep up the water behind the machine.

At high tide the machine is moored in the middle of the channel, the wings are extended and kept so by ropes, and when the tide is at half ebb the plugs are taken out, and the water rises about 2 feet in the machine, which causes it to sink; the plugs are then replaced, and thus it remains till full ebb, when the iron shod frames are let down in front and the tide forces the whole machine, which is like a great dam, gently down the stream, scraping with it all the mud down to the river, where it is emptied, and floated back with the return tide, the whole distance, about 3 miles, is performed in two hours.

A similar machine has appeared in the 2nd vol. of the "Transactions of the Institution of Civil Engineers," p. 181; only the former was used for a drain, and the latter for navigable rivers.

March 12.—The PRESIDENT in the chair.

"A description of the Rhymney Ironworks," accompanied with a "Drawing of the Puddling Forge and Mill," from Mr. Richards.

These works were erected by the author for the Rhymney Iron Company; and he describes the various processes necessary for converting refined metal into finished iron. He states that each furnace receives 4½ cwt. of refined metal as a charge, which is worked into six puddled balls in about a half an hour. These balls are then taken to a shingling hammer, weighing about 4½ tons, with a fall of 20 inches, and the balls are subjected to about twenty-five blows. Instead of this process the balls might be taken to the squeezer, but this method is not so effectual in removing the impurities of the iron; it is then passed to the puddling rolls, where it is gradually reduced to the required size, when it becomes puddled bars. These are then, whilst hot, cut into lengths, and subsequently piled into weights and sizes according to the description of the iron that is about to be rolled. The piles are then brought to a welding heat in heating furnaces, and passed through roughing rolls, till they are reduced sufficiently to go through the finishing rolls, where they are made into bars of the description required. The same operation of shearing, piling, and heating of these bars, and rolling through other rolls forms the railway bars.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

At an ordinary general meeting of the members, held on Monday, the 4th of March, 1839, P. F. Robinson, V. P., in the chair, the following gentleman was elected an associate:—George Ward, of 22, Penton-place, Pentonville.

The report of the Council respecting the adjudication of the medals for the prize essays was read.

Resolved,—That the recommendation of the Council be approved, and that Medals of Merit be awarded to the authors of the papers with the mottoes "Roma fuit," and "Respice ad Palatinum montem vasta rudera."

The letters, bearing the mottoes of the successful candidates, having been opened, the authors appeared to be as follows:—

William Willmer Pocock, Associate of the Essay with the motto "Roma fuit."—Edward Hall, 12, Brown-street, Manchester, of the Essay with the motto "Respice ad Palatinum montem vasta rudera."

The following papers were read:—Description of various specimens of metal sash-bars, manufactured by Mr. Clarke, of Lionel-street, Birmingham; forwarded by Mr. Jones.—Description of a superior quality of crown glass, manufactured by Messrs. Stock and Co., Birmingham.—Description of various sorts of stone used for building purposes in Belgium, by Mons. Serrure, Hon. and Cor. Mem.—Description of double gateway to the city of Pæstum, with a restoration and remarks illustrative of the military architecture of the Greeks, by T. L. Donaldson, Hon. Sec.

Mr. Donaldson read the following extract from a letter he received from Mr. Charles H. Gregory, engaged on the Manchester and Birmingham Railway.

Manchester lies nearly at the north of the red sand-stone district. In the immediate neighbourhood, on the north side, we come into the coal-beds and carboniferous limestone; on the west the sand-stone is continued throughout the greater part of Cheshire to Flint, where we pass through strata of limestone to the clay slate; on the east side, 10 or 12 miles bring us to the borders of Yorkshire and Derbyshire, and to that ridge of moor-hills which has been termed "The Backbone of England;" it is here that the summit-stones are obtained, being a strong grit, and the best building stones for ordinary purposes used in Manchester. The best of the summit stones for strength and durability comes from the Blackstone-Edge Quarries. This stone much resembles the Bramley Fall stone, and will bear nearly as much. The Saddleworth stone is another of the summit stones, but the quarry is not half worked, so that it cannot be so well trusted as the Blackstone Edge. The price of the summit stone at Manchester is from 10*d*. to 1*s*. per foot. Another stone, much used here for Ashlar work, is a red sand stone, obtained at Runcorn, on the Mersey, a few miles from Warrington. The Runcorn stone is rather cheaper than the summit stone (I think it is sold at 6*d*. per foot at the quarries); it works well, but there is a great deal of waste, the stone abounding in clay spots. For cornices, mouldings, &c., where much work is to be put on the stone, the Huddersfield stone is the best suited. This is a very fine sand stone, approaching in texture to the Yorkshire landings—it is very free, and good for tooling; it costs 1*s*. 6*d*. per foot here.

We leave Manchester (on the Manchester and Leeds Railway) by a viaduct, for about 1½ mile in length; for a considerable part of this distance the piers are now up and the imposts laid, waiting for the spring weather before the arches are turned. In the midst of this viaduct there is to be one skew bridge of iron, of about 130 feet span (if I remember rightly).—The next large work along the line is the Stockport Viaduct, about 100 feet high in the highest part, and rather more than one-third of a mile long. The foundations are now being excavated for this work, and it will probably be in active operation in about a month's time.—The viaduct at Congleton will be a still larger work, and is to me more interesting, as I have been actively employed in the preparation of it. The length will be 3,078 feet, the greatest height to the rails 98 feet 6 inches; it consists of 42 arches of 60 feet span, each with piers 10 feet in thickness between them. It will contain about 62,000 cubic yards of brickwork, and 620,000 cubic feet of stone. I do not remember the precise amount at which it is contracted for, but I think it is about £113,000.

Monday, March 18th, 1839, P. F. Robinson, V. P., in the Chair. The meeting proceeded to the ballot for the removal of Sampson Kempthorne, Associate to the class of Fellows, who was declared to be unanimously elected.

A letter was read from the Signor Gaetuxo Beria, of Milan, acknowledging his election as honorary and corresponding member. Also from the S or Atberllolli, of the same place, and from the Signor Klangabe, Secretary of the Archæological Society at Athens.

It was announced by the Secretary that a copy of Professor Phillips's work on Geology, published in Dr. Lardner's Cabinet Cyclopædia, 2 vols., 8vo., would be presented by a member to the most ample and accurate abstract of the course by any associate or student.

The first of a *Course of Six Lectures on the Geology of the South East of England*, was then commenced by G. F. RICHARDSON, Esq., of the British Museum, whose able treatment of the subject was admirably supported by the elegance of his style and the harmony of his delivery. The illustrations were most effective, and among them were a series of drawings of the caves of Adelsberg, near Trieste, which had never before been seen in England.

"Geology," said he, "is a science interesting because it is new, and as Columbus excited the strongest sensations in the old world, by discovering to them the new, so in our days we have, as it were, laid open to us a new creation in the re-discovery of the old. This science has been frequently defined, but never perhaps to sufficient extent, for it is a science which is not restricted to a few objects, but considers the past, the present, and the future, the living and the dead, the whole organic and the inorganic world. It may be divided into dynamical portions, or geology proper, which considers the operation of forces; and palæontology, or the natural history of the antediluvian era."

Geology is a science, which, while too many regard it as merely speculative, is a science of the highest practical utility,—one equally important in mining, agriculture, and the arts. It is by the character of the strata that we determine their mineral deposits, as in granite we find tin, in the transition series lead, and in the alluvial gold; so we have equally pointed out to us the positions, in which, as they are destitute of productions, research would be fruitless. Inattention to these has been too often attended with vexation and loss; and in one instance, within his own experience, the lecturer stated that the late Duchess of Dorset was induced to expend £10,000 in the useless attempt to find coal at Bexhill, in Sussex, although, now, any geologist could have told that the exertion would be as abortive as it is absurd. We regret that, from misconception, Mr. Richardson, in endeavouring to inculcate the utility of a Government school of mines, as on the Continent, stigmatized our present mining operations as the suggestions of avarice and ignorance, for the vilest purposes of jobbery, instead of recognising the wonderful power of that great principle which has enabled Joint Stock Companies to place England in a prouder position, as a mining country, than any of her neighbours, and which, not contented with the native field, has sought a new theatre of exertion across the great Atlantic deep. The importance of geology in determining the productiveness of soils is of paramount utility, and intervenes in all operations in draining; by attending to the fissures in the strata, if they are of a porous nature, we may, by directing branch-channels into them, save more extensive operations; while we can ascertain if the strata be impervious, by observing whether they abound in land-springs. The subject of Artesian wells is one of great interest in this particular district, and it is well deserving of attention in many places, whenever, in seasons of drought, numbers of cattle perish from the want of the great necessary of life. In road-making, in the vicinity of London, we had long pursued an erroneous course, by employing gravel and round pebbles, until, under M'Adam's direction, the use of angular stones was introduced, and new road-materials were furnished from the trap-rocks of Leicestershire.

On the profession, before which this lecture was delivered geology has a particular claim; for is it not from a neglect of its precepts that buildings erected only two centuries ago are severely injured by the weather? This arises from using a calcareous sand-stone, which, imbibing moisture, is decomposed by the agency of the carbonic acid in rain water; while the use of granite is not free from the same defects, the felspar, one of its ingredients, being an equally perishable material: in fact, it is only such stones as siliceous sandstone, which are capable of resisting that insinuating destroyer. The legislature has indeed recognised this connexion of geology with architecture, by sending Mr. de la Beche on a mission through the stone-producing districts of England, to ascertain which possesses the best stone, for the construction of the new Houses of Parliament. The sculptor is also interested in the qualities and durability of his material, and many are both the modern and ancient statues polluted by the iron stain, which spots some of the finest works. The painter cannot disregard this science with impunity; for what can be more improper, than in the representation of some historical event in the undulating scenery of the south of England, as the signing of Magna Charta, or the imprisonment of Charles I., to see it accompanied with the sharp peaks and straggling rocks of the primary or transition strata? A literary friend, a lady of some celebrity, had committed this error; she had described in one of her works the Isle of Sheppey, with the fanciful attributes of chalky cliffs and whitened walls; but, having occasion subsequently to visit it, what was her astonishment to see none of the things she had represented, but only shores bordered with mud! Nor, in its general relations, is geology less attractive than in its physical utility, for most truly does it show us the omnipotence of the Creator, and teaches us to find sermons in stones, and good in every thing. To the architect the whole world offers the contemplation of a kindred work, one mighty temple, reared by Nature to her great Creator: its details beautiful as they are regular; its grandeur towering to the clouds, and its chambers replete with all that can be useful to the favoured people who inhabit it; in truth, a worthy monument of the Great Architect.

In giving a limited sketch of geology, it is impossible to embrace the whole science, and indeed lectures may more truly be regarded as incentives to study, than as supplying the place of study itself. A geologist is indeed called upon to narrate, in the narrow space of an hour, revolutions of centuries, and the history of a million years. He is, in truth, like a traveller carried at railway speed through a delightful country, and has only time to enumerate the objects which he cannot describe.

In nature, as in revelation, all is regular, all is systematic, and every apparent divergence serves only to confirm the wonderful provisions of the whole. The dislocations which occur in strata, so far from being produced by confusion or blind chance, are purposely placed, like magazines, to supply us with the riches of the mineral world; and here we have stored up resources which otherwise would have been sunk far beneath our means of search. The terms used in geology, however difficult they may appear in name, are perfectly simple in their explanation; as, when we use the term *anticlinal strata*, we only express that formation which resembles the ridge made by the roof of a house. Many of these terms have no existence in nature, but are employed, as in other sciences, to assist the imperfection of our mental powers; thus—we say primary, transitive, secondary strata, as in music we use bars to mark the time, without any reference to the existence of such in the execution of the piece. Geology, however, is a science in which, like astronomy, we must doubt the evidence of our senses, and perpetually expect results for which on first impressions we are unprepared; like as in that we are taught that the sun, apparently ever moving, is yet a stationary globe, so here we are told that what was once land is now sea, and that the firm ground on which we stand was floated over by the monsters of the deep; that the hard and ponderous rock was once as soft and yielding as the quicksand; and that the very stones before us in former days walked the wind as things of life. The inquirer into geology finds himself like Aladdin in the cave; at first the rocks seem to close around him and shut out all hope, but no sooner has he gained the talisman of science, than a fairy land of wonder breaks upon his view. To the man of the world no science can be more practically useful, to the philosopher nothing more agreeable, and to the Christian nothing more satisfactory; for here he finds the fleeting existence of man chronicled as surely as in holy writ, and here he sees the eternity of the Great Creator, when he witnesses the successive destruction of rocks that almost seem to outvie time, and powers that seem as they could conquer it.

Monday, March 25th.—H. J. Robinson, Esq., V.P., in the chair.

Mr. Richardson gave his second lecture on Geology, in which he considered the rocks with reference to their zoological relations, and their adaptation to the necessities of mankind. The lecturer commenced by recapitulating the topics of his introductory discourse, and enforcing the definition of geology as a science which requires the investigation of every branch of organic and inorganic nature, which in the extent of its disquisitions is occupied with the past, the present, and the future. He again recalled its moral tendency, the manner in which it proves the perishability of matter, by showing the successive decay of every substance on the surface of the earth, and the powerful lesson which it teaches us of referring everything to its first cause, and looking to the great Creator as alone immutable, eternal, imperishable.

The greater portion of the crust of the earth, and the secondary and tertiary portions in particular, Mr. Richardson showed not only to be derived from the destruction of previous bodies, but absolutely from living beings. These remains are not confined to the gigantic relics which strike every eye, but they are to be traced in those minute organizations which are scarcely recognizable even by the microscope. Piles of rocks, beyond calculation and imagination, are formed by the infusorial insects and the coral tribes, and, as if to show the vastness of his power, it is by means of these tiny labourers that the Almighty has called into existence his most magnificent works. The pebble that we hold in our hands may once have lived in a thousand breathing forms, and seen the history of centuries; and, as Young says,—

" Where is the dust that was not once alive?"

The very rocks that now upheave their crests to heaven, once crawled in earliest forms upon the earth, and from insects which we should crush in the height of our fancied power, a greater Being has devoted to fabricate his nobler monuments. Even the primary rocks themselves have not been supposed to be exempt from the alloy of animal remains; and the observations of the Rev. Mr. Reade, of Clapham, have induced him to suspect their presence in mica and opal of porphyry. In mica he has perceived, by his microscope, annular or ringlike impressions, which he cannot but refer to the remains of infusoria, although, from the constitution of primary rocks, crystalized by heat to their minutest molecules, this result has been doubted by many. To the microscope, however, we must look for the elucidation of this subject, and even when we are far from having availed ourselves of its present powers, we may look forward to a period when it will have attained a greater perfection, while only recently its powers have been augmented 50 per cent.

In the primary rocks no well-defined organic remains appear, and it is not until we came to trilobitic schist that we obtain satisfactory testimony of their presence. This stone derives its name from the trilobite, an animal of the crustaceous tribe, most nearly allied to the king-crab, and which is chiefly remarkable for the beautiful structure of its eye. This organ, which has 3 or 400 lenses, Dr. Buckland, in his " Bridgewater Treatise," has adduced to prove the similarity of constitution between the atmosphere and ocean of the ancient world and that which now exists, proving that it has remained unaltered in its properties in all the immensity of time. The secondary rocks are indeed most important in their zoological character, and here it is that we meet those anomalous animals, the ichthyosaur, or fish-lizard, and its ally the plesiosaur. In the oolite, which is most important for its constructive uses, we find the megalosaur, or great lizard, shells, ammonites and other vestiges of its marine formation. It is from this class of rocks that we obtain Freestone, Bathstone, and Portlandstone. In the Wealden formation which succeeds it we find many interesting features. The Sussex marble is formed almost exclusively of snail shells, such as lived in the great river of which the Weald district was once the bed. This marble affords some most beautiful columns to Chichester Cathedral, and it is the material of which the archbishop's throne at Canterbury is formed. To the same class also belongs Purbeckstone. We now come to the chalk which is the boundary of the secondary formation, and is distinguished by the presence of the spirolimite, a microscopic shell, allied to the nautilus and the argonaut, for the discovery of which we are indebted to that eminent philosopher and amiable man the Marquis of Northampton, President of the Royal Society, who was present at the previous lecture. In the tertiary strata we find vestiges of the marine and freshwater animals which formerly inhabited the site of these deposits, and no district is more interesting than the London clay. In this and in the fresh-water rocks of the Isle of Wight we find the nummulite, so called from its resemblance to a Roman coin, and it is of stone formed of this shell that the great Pyramid of Gizeh is constructed. Strabo noticed the appearance of this shell, and he attributed it to the remains of the lentils on which the workmen fed, and which he supposed, having been thrown on the spot, had been petrified. This nummulitic rock is one of the latest formations, and yet, as if to stamp man a parvenu on the earth of which he boasts himself master, the earliest of his works are but nature's last.

Having thus exhibited the manner in which the zoology of a rock demonstrates its character, the lecturer proceeded to illustrate the application of geology to the practice of construction. He truly observed, that this science, by showing the advantages and defects of strata, became of the highest importance to the architect and the engineer. It would be absurd, he said, for him, to teach architecture to architects; but, while on this subject, he might perhaps be permitted to make one cursory allusion bearing on this subject. In the 14th chapter of Leviticus, from the middle to the end of the chapter, there are some curious provisions, not generally observed, with regard to the leprosy of a house, as derived from defects in its position or construction, and showing the attention which the inspired legislator devoted even to this subject. With regard to the influence of strata upon foundations, he supposed those points to be well known; and as time did not admit a longer detail, he must run cursorily over some few points which he should have wished to have given at greater length. Rocks, he remarked, are divided into two great classes from their origin—the igneous from fire, and the aqueous from water or slate; and the different kinds of useful stone range from the primary strata upwards through every gradation—from primary limestone to slate, sandstone, magnesian limestone, and oolite. The main qualities for a good building stone are firmness and consistency, and one of the best empirical rules by which an architect can judge of the stone of a district is by observing its oldest buildings, which, if affected by the weather, are principally injured on its north and west sides. The best way to ensure the greatest degree of resistance in a stone is to place it in the same way as it is in the quarry, that is, horizontally; and this is particularly necessary in laminated strata and those of the tertiary formation, of which most of the buildings in Paris are constructed. Argillaceous limestong also, which comes soft from the quarry, and hardens afterwards, requires reat care and attention. Stones of unequal colour, spotted, or veined, arenot so strong as those of uniform colour, and should be avoided, as they are dangerous; and sometimes, as in the case of arches, one stone of this description will, from its failure, ruin the whole work. Spots of oxide of iron or of manganese are equally bad omens, as the stones on which they exist are liable to action from the weather. Argillaceous stones generally contain mica, and this is so susceptible of wet, as greatly to deteriorate from their qualities. Brown or black stones generally exfoliate in laminæ, from their ready absorption of moisture, so that they should only be used in places under cover, where they are secure from this dangerous agent. Moisture, indeed, from the compactness of its atoms when frozen, injures stones apparently of the strongest constitutions, and this is the weak side of granites, syenite, porphyry, and breccia, which frequently, from this cause, exhibit fissures. Stones, therefore, which are to be used above the surface, should not be of moist tendency, but such should be reserved for subterranean purposes. The consequence of absorption of moisture, as before observed, is liability to injury from frost; and, to ascertain this susceptibility, one of the simplest methods is to allow a piece of the stone to remain in water, and then to weigh it, to find out the quantity imbibed. Another method recently introduced is to take a small cube of stone, dip it in a solution of some salt, and then to hang it for a few days over the vessel containing the salt, so as to allow the salt to crystallize on its surface; this process is to be repeated for five days, and then, if the stone be good, no sand or fragments of the stone will be discoverable in the solution; but if it be liable to injury from frost, then corners of the cube or sand will be deposited in the vessel over which it hung. Wet stones, when brought from the quarry, should be dried, because it is found that the mortar will not adhere to them, and that if the stone be wet it will always remain so. Stones should also be left for twelve months before they are used, in order to see in what manner they are affected.

Granite formed of mica, felspar, and quartz, is liable, from its first constituent, to destruction by weather, although it is a material susceptible of the highest uses. Not to speak of the many magnificent works formed from this material in Egypt, we have noble specimens in Waterloo Bridge, and the King's Library in the Museum, in which latter four columns of Aberdeen granite cost each 1,500*l.*, or 16,000*l.* for the set. Syenite is composed of the same constituents as granite, with the substitution, however, of hornblende for mica, and derives its name from the city of Syene, in Egypt, by the people of which it was much used. Gneiss is a slaty granite, and is, from this definition, not very useful. Quartz is principally adapted for subterranean localities, and is used for foundations. Porphyry was used most extensively by the Egyptians, and so was the striped stone called serpentine, of which even cups and vases were formed. The volcanic rocks are divided into basaltic and trachitic; the basaltic contain a portion of iron, and are used for fortifications, and also in the Cathedral of Cologne; the trachitic rocks are also used most extensively on the banks of the Rhine, even for the purpose of milestones. Of the white marble of the lias formation—that treasure of the British Museum—the Birth of St. John, by Albert Durer, is executed.

It seems as if, by Divine interposition, the very arrangement of the strata is made conducive to human convenience and advantage; from the primary and transition strata we derive our hardest materials, and from the secondary and tertiary, our limes and cements. All, indeed, leads us upwards to the Deity, through Nature to Nature's God; and our investigation of his glorious works is one of the best acknowledgments we can make of his power and love, and of the manner in which he has devoted the most wonderful agencies to be blessings to us during our stay on earth.

ARCHITECTURAL SOCIETY.

The following donations were announced:—

Milner's Treatise on Ecclesiastical Architecture in England, by H. Roper, Esq.

Chapman's Observations on Canal Navigation, by H. Roper, Esq.

Voyage Pittoresque ———— dans le Province d' Yucatan, par Frederick de Waldeck, by William Tite, Esq., President.

Letter to Lady Duncannon, by Thomas Hopper, Esq.

Sir Edward Cust's Pamphlet, by Thomas Hopper, Esq.

Mr. Brayley delivered a lecture "On the Chemical History of Cements, and of the Artificial Substances employed as Substitutes for Stone," being the third of a course now in progress of delivery.

The Chairman announced "That the next public meeting of the Society would be held on Tuesday evening, the 9th April, when Mr. Brayley would deliver his fourth and concluding lecture. The subject to be "On these physical and chemical properties of Building Stones on which their use essentially depends."

That the meeting to be held on the 23d April would be a public meeting for the introduction of visitors, and that Mr. Jeffreys, the inventor of a new grate for effectually warming rooms, &c. would read a paper "On the Warming and Ventilating of Rooms."

THE MANCHESTER ARCHITECTURAL SOCIETY'S CONVERSAZIONE.

The first conversazione of this society, in the present season, was held on Wednesday evening, the 6th ultimo, when the new rooms of the society, No. 24, Cooper-street, were opened. Mr. Andrew Hall, who had recently been elected president of the society, took the chair, and congratulated the members on their assembling together in their new apartments, under favourable circumstances. Mr. J. W. Hance, honorary secretary, stated that the rooms would, in future, be open from nine in the morning to seven in the evening, for studying from casts; and that the library would be accessible, from seven to nine o'clock, every Wednesday and Saturday evening. He had also great pleasure in adverting to a circumstance, highly gratifying to the society, and honourable to the individual to whom he was about to refer. A letter had been received from Mr. Thomas L. Donaldson, honorary secretary of the Royal Institute of British Architects, stating that the council of that body had awarded their medal to a member of this society, for his successful essay. Mr. Hance then read the following letter, addressed to Mr. Edward Hall (applause):—

"5th March, 1839.

"Sir,—I have the honour to inform you, that, the council having made their report upon the essays sent in for the medal of the institute, at the ordinary meeting, held last evening, the members awarded to you the medal of merit, for the essay bearing the motto,—'*Respice ad Palatinam Montem—vasta rudera.*' I shall communicate to you the day appointed for the distribution of the medals as soon as the council have appointed the time, which will probably be shortly.—Believe me, sir, very faithfully yours,

"THOS. L. DONALDSON, Honorary Secretary."

The subject and title of the essay, as fixed by the British Institute, is "An analytical investigation of the peculiar characteristics, in design and construction, which distinguished Roman from Grecian architecture, with particular reference to ancient Roman examples." Mr. Hance added that Mr. Hall, who was present, was, as they were all aware, a very young man; and he (Mr. Hance) trusted that his merit and success would stimulate others. He hoped that this society would in time be enabled to offer honorary rewards for drawings and essays; the council had wished to do so, but they felt that their exertions must first be directed to settling the society in their new premises. The chairman briefly acknowledged the kind wishes expressed towards his son, of whose success he had only heard a few hours before, on his own return from Ireland. Mr. Hance next expressed the pleasure of the society at the presence, for the first time, of resident artists. It would be seen by the walls that the conversazione was not limited to architectural subjects; and it was intended to place works of art, generally of standard merit, on the walls and tables, without distinction or reserve. He expressed his regret that another series of conversazione had fallen into disuse, and the hope that, with the aid and support of artists and amateurs, those of this society, proposed to be held quarterly, would assume a rank creditable to all parties. In conclusion he expressed the thanks of the society to Mr. Andrew Hall, its president, for his kind interest in and attention to its welfare. The greater part of the evening was agreeably spent by the members and visitors, in looking at the drawings and works of art upon the walls and tables. Mr. R. Tattersall contributed several interiors of halls, library, &c. and designs for a church, and for a club house. Mr. J. W. Hance had drawings of the pump-room at Cheltenham, the hall of the Manchester Royal Institution, a design for a new post-office, exchange, bank, and other public offices (which, it was stated, was about to be published), and a design for a picture gallery. Mr. J. W. Fraser contributed a number of pleasing landscapes in oil, and drawings; Mr. T. W. Atkinson, an interior of Sefton church, and an architectural design. Mr. Horner sent a large oil painting decoration for a room, and there was another very fine decorative piece in a new style. Mr. J. C. Grundy contributed a number of paintings and drawings, amongst which we noticed a fine landscape by Carmichael; and Mr. Agnew also sent some. There was a very neat isometrical view of Hardwick Hall, Derbyshire (a seat of the Duke of Devonshire), contributed by Mr. C. J. Julott. Mr. E. Corbett sent an elevation for a bank at Liverpool. There was a very good full-length portrait in oil, small size, of Mr. C. A. Duval, artist, painted by himself; and we noticed a pretty little oil-painting of a village inn, by Chester. Mr. Calvert and other artists also sent water-colour drawings; and the collection generally was a very pleasing one. On the tables were various portfolios of engravings, illustrated books on art, including Richardson's Illustrations of the Architecture of Elizabeth and James I.; Flaxman's designs; Robert's Spain and Morocco; Stansfield's sketches, &c., &c. Mr. J. E. Bowman placed on the table a number of the photogenic drawings of ferns, lace, &c. and a copy produced by this newly-discovered means, from a small copper-plate engraving. In conclusion, we are happy to state, that every one present at this very agreeable conversazione seemed to be highly gratified with the objects of interest provided for their inspection.—*Manchester Guardian.*

ROYAL SOCIETY.

Feb. 28.—Observations on the Parallel Roads of Glen Roy and of other parts of Lochabar, with an attempt to prove that they are of marine origin. By CHARLES DARWIN, Esq., M.A.

The author premises a brief description of the parallel roads, shelves, or lines, as they have been indefinitely called, which are most conspicuous in Glen Roy and the neighbouring valleys, referring for more detailed accounts to those given by Sir Thomas Dick Lauder, in the Transactions of the Royal Society of Edinburgh, and by Dr. M'Culloch, in those of the Geological Society of London. Both these geologists endeavour to explain the formation of these shelves, on the hypothesis of their resulting from depositions of the margin of lakes, which had formerly existed at those levels. The author however shows that this hypothesis is inadmissible, from the insuperable difficulties opposed to any conceivable mode of the construction and removal, at successive periods, of several barriers of immense size, whether placed at the mouths of the separate glens or at more distant points. He does not, however, propose the alternative that the beaches, if not deposited by lakes, must of necessity have been formed by channels of the sea, because he deems it more satisfactory to prove, from independent phenomena, that a sheet of water, gradually subsiding from the height of the upper shelves to the present level of the sea, occupied for long periods, not only the Glens of Lochabar, but the greater number, if not all, the valleys of that part of Scotland, and that this water must have been that of the sea. It is argued by the author, that the fluctuating element must have been the land, from the ascertained fact of the land rising in one part, and at the same time sinking in another; and therefore, that this change of level in Scotland, attested as it is by marine remains being found at considerable heights both on the eastern and western coasts, implies the elevation of the land, and not the subsidence of the surrounding waters. The author next shows that in all prolonged upward movements of this kind, it might be predicted, both from the analogy of volcanic action and from the occurrence of lines of escarpment, rising one above the other in certain regions, that, in the action of the subterranean impulses, there would be intervals of rest. On the hypothesis that the land was subjected to these conditions, it appears that its surface would have been modelled in a manner exactly similar, even in its minute details, to the existing structure of the valleys in Lochabar. Considering that he has thus established his theory, the author proceeds to remove the objections which might be urged against its truth, derived from the non-extension of the shelves, and the absence of organic remains at great altitudes. He then shows how various details respecting the structure of the Glens of Lochabar, such as the extent of corrosion of the solid rock, the quantity of shingle, the numerous levels at which water must have remained, the forms of the heads of the valley, where the streams divide, and especially their relation with the shelves, and the succession of terraces near the mouth of Glen Spean, are all explicable on the supposition that the valleys had become occupied by arms of a sea which had been subject to tides, and which had gradually subsided during the rising of the land; two conditions which could not be fulfilled in any lake. From the attentive consideration bestowed by the author on these several and independent steps of the argument, he regards the truth of the theory of the marine origin of the parallel roads of Lochabar—a theory of which the foundation-stone may be said to have been laid by the important geological researches of Mr. Lyell, establishing the facts of continents having slowly emerged from beneath the sea—as being sufficiently demonstrated. The author states, in the concluding part of his paper, the following as being the chief points which receive illustration from the examination of the district of Lochabar by Sir Thomas Dick Lauder, Dr. M'Culloch, and himself. It appears that nearly the whole of the water-worn materials in the valleys of this part of Scotland were left, as they now exist, by the slowly retiring waters of the sea; and the principal action of the rivers since that period has been to remove such deposits; and, when this had been effected, to excavate a wall-sided gorge in the solid rock. Throughout this entire district, every main, and most of the lesser inequalities of surface are due, primarily, to the elevating forces, and, secondarily, to the modelling power of successive beach-lines. The ordinary alluvial action has been exceedingly insignificant, and even moderately sized streams have worn much less deeply into the solid rock than might have been anticipated, during the vast period which must have elapsed since the sea was on a level with the upper shelves: even the steep slopes of turf over large spaces, and the bare surface of certain rocks, having been perfectly preserved during the same lapse of time. The elevation of this part of Scotland, to the amount of at least 1,278 feet, was extremely gradual, and was interrupted by long intervals of rest. It took place either during the so-called "erratic block period," or afterwards; and it is probable that the erratic blocks were transported during the quiet formation of the shelves. One of these was found at an altitude of 2,200 feet above the present level of the sea. The most extraordinary fact is, that a large tract of country was elevated to a great height, so equably, that the ancient beach-lines retain the same curvature, or nearly so, which they had when forming the margin of the convex surface of the ancient waters. The inferences drawn by the author from these facts, and which he corroborates by other evidence, are, that a large area must have been uplifted, and that its rise was effected by a slight change in the convex form of the fluid matter on which the crust of the earth rests: and therefore that the fluidity of the former is sufficiently perfect to allow of the atoms moving in obedience to the law of gravitation, and consequently of the operation of that law modified by the centrifugal force: and lastly, that even the disturbing forces do not tend to give to the earth a figure widely different from that of a spheroid in equilibrium.

March 7.—The Marquis of Northampton, President, in the chair.

George Gulliver, Esq., and George Godwin, junior, Esq., were elected Fellows.

The following papers were read:—

1. *Researches in Physical Geology, Third Series,* '*On the Phenomena of Precession and Nutation, assuming the interior of the earth to be a heterogeneous fluid,*' by W. Hopkins, Esq. M.A.

Having, in his last memoir, completed the investigation of the amount of precession and nutation, on the hypothesis of the earth's consisting of a homogeneous fluid mass contained in a homogeneous solid shell, the author here extends the inquiry to the case in which both the interior fluid and external shell are considered as heterogeneous. After giving the details of his analytical investigation, he remarks that he commenced the inquiry in the expectation that the solution of this problem would lead to results different from those previously obtained, on the hypothesis of the earth's entire solidity. This expectation was founded on the great difference existing between the direct action of a force on a solid, and that on a fluid mass, in its tendency to produce a rotatory motion; for, in fact, the disturbing forces of the sun and moon do not tend to produce directly any motion in the interior fluid, in which the rotatory motion causing precession and nutation is produced indirectly by the effect of the same forces on the position of the solid shell. A modification is thus produced in the effects of the centrifugal force, which exactly compensates for the want of any direct effect from the action of the disturbing forces; a compensation which the author considers as scarcely less curious than many others already recognized in the solar system, and by which, amidst many conflicting causes, its harmony and permanence are so beautifully and wonderfully preserved. The solution of the problem obtained by the author destroys the force of an argument, which might have been urged against the hypothesis of central fluidity, founded on the presumed improbability of our being able to account for the phenomena of precession and nutation on this hypothesis, as satisfactorily as on that of internal solidity. The object, however, of physical researches of this kind, is not merely to determine the actual state of the globe, but also to trace its past history, through that succession of ages in which the matter composing it has probably passed gradually through all the stages between a simple elementary state to that in which it has become adapted to the habitation of man. In this point of view the author conceives the problem he proposes is not without value, as demonstrating an important fact in the history of the earth, presuming its solidification to have begun at the surface—namely, the permanence of the inclination of its axis of rotation, from the epoch of the first formation of an exterior crust. This permanence has frequently been insisted on, and is highly important as connected with the speculations of the author on the causes of that change of temperature which has probably taken place in the higher latitudes; all previous proofs of this fact having rested on the assumption of the earth's entire solidity, an assumption which, whatever may be the actual state of our planet, can never be admitted as applicable to it at all past epochs of time, at which it may have been the habitation of animate beings. The author concludes by expressing a hope that he may be enabled to prosecute the inquiry still further, and to bring before the Royal Society, at a future time, the matured results of his speculations.

2. '*On the Male Organs of some of the Cartilaginous Fishes,*' by John Davy, M.D.

In this paper, which is wholly occupied with anatomical details, the author refers to his paper on the torpedo, which was published in the Philosophical Transactions for 1834; and also to Muller's work, 'De Glandularum Secernentium Structura Penitiori,' whose descriptions and views are not in accordance with those given in that paper. In the present memoir he adduces evidence of the accuracy of his former statements, and offers some conjectures respecting the functions of several organs found in cartilaginous fishes, but does not pretend to attach undue importance to his speculations.

March 14.—J. W. Lubbock, Esq., V.P. and Treas., in the chair.

G. W. Featherstonhaugh, Esq. was re-elected; and Clement Tudway Swanston, Esq. was elected a Fellow.

The following papers were read:—

1. '*An Experimental Inquiry into the Formation of Alkaline and Earthy Bodies, with reference to their Presence in Plants, the influence of Carbonic Acid in their Generation, and the equilibrium of this Gas in the Atmosphere;*' by Robert Rigg, Esq. Communicated by the Rev. J. B. Reade.

The object of the author in the present memoir is to show, that the solid materials which compose the residual matter in the analysis of vegetable substances, and which consist of alkaline and earthy bodies, are actually formed during the process of fermentation: whether that process be excited artificially by the addition of a small quantity of yeast to fermentable mixtures, or take place naturally in the course of vegetation, or of spontaneous decomposition. His experiments also tend to show, that this formation of alkaline and earthy bodies is always preceded by the absorption of carbonic acid, whether that acid be naturally formed, or artificially supplied. He finds, also, that different kinds of garden mould, some being calcareous, others siliceous, and others aluminous, exposed in retorts to atmospheres consisting of a mixture of carbonic acid gas and common air, absorbed large quantities of the former, combining with it in such a manner as not to afford any traces of this carbonic acid being disengaged by the action of other acids. He considers the result of this combination to be the formation of an alkaline body, and also of a colouring matter. This combination takes place to a greater extent during the night than during the day; and in general, the absorption of carbonic acid by the soil is greatest in proportion as it is more abundantly produced by the processes of vegetation; and conversely, that it is least at the time when plants decompose this gas, appropriating its basis to the purposes of their own system. Hence, he conceives, that there is established in nature, a remarkable compensating provision, which regulates the quantity of carbonic acid in the atmosphere, and renders its proportion constant.

2. '*Note on the Art of Photography, or the Application of the Chemical Rays of Light to the Purposes of Pictorial Representation,*' by Sir John F. W. Herschel, Bart.

The author states, that his attention was first called to the subject of M. Daguerre's concealed photographic processes, by a note from Capt. Beaufort, dated the 22nd of January last, at which time he was ignorant that it had been considered by Mr. Talbot, or by any one in this country. As an enigma to be solved, a variety of processes at once presented themselves, of which the most promising are the following:—First, the so-called de-oxidising power of the chemical rays in their action on recently-precipitated chloride of silver; secondly, the instant and copious precipitation of a mixture of a solution of muriate of platina and lime-water, by solar light, forming an insoluble compound, which might afterwards be blackened by a variety of agents: thirdly, the reduction of gold in contact with de-oxidising agents: and fourthly, the decomposition of an argentine compound, soluble in water exposed to light, in an atmosphere of peroxide of chlorine, either pure or diluted. Confining his attention, in the present notice, to the employment of chloride of silver, the author inquires into the methods by which the blackened traces can be preserved; which may be effected, he observes, by the application of any liquid capable of dissolving and washing off the unchanged chloride, but of leaving the reduced, or oxide of silver, untouched. These conditions are best fulfilled by the liquid hyposulphites. Pure water will fix the photograph, by washing out the nitrate of silver, but the tint of the picture resulting is brick-red; but the black colour may be restored, by washing it over with a weak solution of hyposulphite of ammonia. The author found that paper impregnated with the chloride of silver was only slightly susceptible to the influence of light; but an accidental observation led him to the discovery of other salts of silver, in which the acid, being more volatile, adheres to the base by a weak affinity, and which impart much greater sensibility to the paper on which they are applied—such as the carbonate the nitrate, and the acetate. The nitrate requires to be perfectly neutral; for the least excess of acid lowers, in a remarkable degree, its susceptibility. In the application of photographic processes to the copying of engravings or drawings, many precautions, and minute attention to a number of apparently trivial, but really important circumstances, are required to insure success. In the first transfers, both light and shadow, as well as right and left, are the reverse of the original; and to operate a second transfer, or by a double inversion to reproduce the original effect, is a matter of infinitely greater difficulty, and in which the author has only recently ascertained the cause of former failures, and the remedy to be applied. It was during the prosecution that these experiments that the author was led to notice some remarkable facts relating to the action of the chemical rays. He ascertained the contrary to the prevailing opinion: the chemical action of light is by no means proportional to the quantity of violet rays transmitted, or even to the general tendency of the tint to the violet end of the spectrum; and his experiments lead to the conclusion, that, in the same manner as media have been ascertained to have relations *sui generis* to the calorific rays, not regulated by their relations to the rays of illumination and of colour, they have also specific relations to the chemical spectrum, different from those they bear to the other kinds of spectra. For the successful prosecution of this curious investigation, the first step must consist in the minute examination of the chemical actions of all the parts of a pure spectrum, not formed by material prisms, and he points out, for that purpose, one formed in Frauenhofer's method, by the interference of the rays of light themselves in passing through gratings, and fixed by the heliostat. He notices a curious phenomenon respecting the action of light on nitrated paper; namely, its great increase of intensity under a certain kind of glass strongly pressed in contact with it—an effect which cannot be explained either by the reflection of light or the presence of moisture, but which may possibly be dependent on the evolution of heat. Twenty-three specimens of photographs made by Sir John Herschel accompany this paper; one a sketch of his telescope at Slough, fixed from its image in a lens, and the rest copies of engravings and drawings, some reverse, or first transfers, and others second transfers, or re-reversed pictures.

GEOLOGICAL SOCIETY.

Feb. 27.—The Rev. Dr. Buckland, President, in the Chair.

The following communications were read:—

1. "*On Impressions of Drops of Rain on Slabs of New Red Sandstone, in the Storeton Quarries, Cheshire, and coeval with the formation of the Strata,*" *by Mr. John Cunningham, of Liverpool.*—In a paper read before the Society on the 3rd of December, an account was given of the impressions of footsteps of several species of animals in the new red sandstone of the Storeton Quarries, about three miles south-west of Liverpool. In examining some of the slabs of stone, extracted at the depth of above thirty feet, Mr. Cunningham observed, that their under surface was densely covered with minute hemispherical projections, or casts in relief of circular pits in the immediately subjacent layers of clay. The origin of these marks, he is of opinion, must be ascribed to showers of rain, which fell upon an argillaceous beach exposed by the retiring tide, and their preservation to the filling up of the indentations by sand. On the same slabs are impressions of feet of small reptiles, which appear to have passed over the clay previously to the shower, since the foot-marks are also indented with circular pits, but to a less degree, and the difference Mr. Cunningham explains, by the pressure of the animal having rendered those portions of the clay less easily acted upon. That rain fell during remote ages of the world, the author stated, no person acquainted with geology will dispute: as, to the destructive and transporting agency of rain-waters many of the sedimentary strata owe their origin. The vast forests also, which grew at a period anterior to the new red sandstone, and are now treasured up in our coal fields, could not have flourished without abundant supplies of atmospheric waters; and, that the effects of drops of rain may be preserved in a solid form, he proved by reference to an account given by Mr. Scrope of a shower which fell upon extremely fine volcanic ashes thrown out by Vesuvius during the eruption of 1822. The drops of rain formed small globules, which hardened into pellets, and accumulated in some places at the foot of a slope, in beds a foot or more in thickness, and were often so agglutinated that it required a sharp blow from a hammer to break the mass.

2. Extracts from two letters addressed to Dr. Buckland: one from Mr. John Taylor, jun., on the occurrence of a slab of sandstone containing impressions of Chirotherium Hercules at the house of Mr. Potts, of Chester; and the other by Sir Philip Egerton, on the peculiarities of the impressions. When the slab was first laid down there was no appearance of the remains which have been gradually developed by the action of the weather. Sir Philip Egerton is of opinion that the weight of the animal compressed the yielding sand near its foot, and that the print being afterwards filled with the same materials, the stone became nearly homogeneous in composition. The effects of the weather would necessarily remove the softer uncompressed portions, but the denser part acted upon by the animal's weight, would resist for a time the same operations, and present in relief the outline of the foot. The slab contains the marks of three hind and two fore-feet, the latter bearing the same proportion in size to the former, as in the other species.

3. "*On the Occurrence of Swallow-holes near Farnham, and on the Drainage of the Country at the Western Extremity of the Hog's-back,*" *by George Long, Esq., communicated by Mr. Lyell.*—Immediately to the north of Farnham, rises a chalk hill, capped by tertiary strata. No perennial main-springs occur on the face of the hill, but the gulleys are, for the greater part of the year, occupied by superficial land-springs, which occasionally become formidable torrents. These rivulets pour down the hill upon the surface of the tertiary clay, until they arrive at the chalk, where they are entirely absorbed in swallow-holes, except during great rains, when a portion of the water flows along channels in the chalk. Seven of these holes, between Clare Park and Farnham Park, were described in detail by Mr. Long. The water absorbed by two of them is supposed to well out in great force at the Bourne mill-stream; and, though soft where it sinks under ground, it is hard when it re-appears. The drainage, described in the second part of the paper, is effected by a stream, which passes through a gap at Runfold, the western extremity of the Hog's-back hill, and flowing northward through the chalk, carries off the surplus waters of a tract bounded on the north by the Hog's-back, and on the south by a semi-circular range of low hills, extending from Seal, on the east by Crooksbury, to Moor Park, on the west. This gap in the chalk has hitherto escaped the observation of geologists, but deserves to be recorded among the apertures through the North Downs.

4. "*A Letter from Capt. Charters to Mr. Lyell, dated Cape Town, Nov.* 12, 1838."—During a very extensive tour through the colony, Captain Charters's attention was particularly drawn to the occurrence of greenstone resting upon the horizontally stratified sandstone, which constitute so large a portion of the country. The localities mentioned in the letter are in the neighbourhood of Fort Beaufort, on the Kaffir frontier, the small town of Cradock on the Great Fish River, the line of route from the Tarka district behind the Winterberg range to Shiloh, and to Colesberg, near the Orange River, and thence by the Schneeberg to Graf Reinet. In some places the trap presented thick deposits, more or less traversed by irregular cracks; and, in others, heaps of weathered or spheroidal masses, resembling transported boulders.

ASIATIC SOCIETY.

Feb. 16.—Sir George Thomas Staunton, Bart., M.P., in the Chair.

Mr. Wilkinson read a paper, "*On the Difference between the European and Indian Methods of making* Steel, *and on the reasons which induced him to ascribe many of the properties of iron, and much of the variety in its quality, to the action of electricity.*" After adverting to the extraordinary discoveries of Professor Ehrenberg, of Berlin, who has shown that the bog iron ore, from which the beautiful Berlin castings are made, is composed of minute animals, that Tripoli powder is of a similar nature, and that the ditches about Berlin abound in such animals, Mr. Wilkinson stated that these wonderful animals had recently been found in England also, and that in localities so near as Hampstead and Highgate. Mr. Wilkinson then entered into a description of the mode of manufacturing iron, and of the process by which it is converted into steel, both in England and India, which differ essentially; the English process being chiefly exposure of the iron to strong heat, in close contact with charcoal; while the natives of India put the iron into crucibles with dried branches of a certain shrub, and green leaves of others. Mr. Wilkinson then adduced arguments corroborative of the opinion, that the different properties of iron and steel depend on currents of electricity, which, however, he admitted were not conclusive; and he expressed his intention of instituting a set of experiments, with a view to ascertain its truth, and its applicability to practical purposes. He hoped shortly to obtain some specimens of Indian steel, and to receive replies to several queries on the subject, sent by him to India through the medium of the Society, which would enable him to proceed with more certainty.

Mr. Heath said, that a copy of Mr. Wilkinson's queries had been sent to him by the Madras government, to whom the Society had transmitted them in 1837; that his labours were at that time too great to admit of his giving close attention to the subject; but that on his voyage home he had written a paper, which he conceived embodied all that was required on the subject, and which he would now read. Mr. Heath's paper entered largely into the nature of the Indian ore, and the operations of the natives in manufacturing it into iron and steel. He said that the ore used was the magnetic oxide of iron combined with quartz, in the proportion of fifty-two of oxide to forty-eight of quartz; that it occurs in the district of Salem, the principal seat of the manufacture, in the form of low hills; and that the quantity exposed above the surface of the country is so great that it was not likely that underground operations would ever be required. It is prepared by stamping, and then separating the quartz by washing or winnowing. The furnace is built of clay alone, from three to five feet high, and pear shaped: the bellows is formed of two goat-skins, with a bamboo nozzle, ending in a clay pipe. The fuel is charcoal, upon which the ore is laid, without flux; the bellows are plied for four hours, when the ore will be found to be reduced: it is taken out, and when yet red hot, cut through with a hatchet, and sold to the blacksmiths, who forge it into bars, and convert it into steel. It is forged by repeated heating and hammering, until it forms an apparently unpromising bar of iron, from which an English manufacturer of steel would turn with contempt, but which the Hindu converts into cast steel of the very best quality. To effect this he cuts it into small pieces, of which he puts a pound, more or less, into a crucible, with dried wood of the *Cassia auriculata*, and a few green leaves of *Asclepias gigantea*. The air is then excluded by a cover of tempered clay rammed down close into the crucible. When dry, about twenty crucibles are built up in a small furnace, covered with charcoal, and heated for two hours and a half, when the process is complete. Mr. Heath observed, that the quality of the steel was excellent; but that the process of smelting was so imperfect, that of seventy-two per cent., of which the oxide is composed, only fifteen per cent. of iron was obtained by the natives. The discovery of steel by the Hindus appeared one of the most astonishing facts in the history of the arts; it seemed too recondite to be the effect of chance, and yet could only be explained by the lights of modern chemistry. In Europe the case was otherwise. In the early times, repeated hammering after refining, appears to have been the only process; and cementation by charcoal was not adopted until chemical investigation had shown that steel was a compound of iron and carbon. Two patents had been taken out within the present century; one for making steel by the application of "any substance containing the carbonaceous principle;" and another, by exposing the iron to the action of carburetted hydrogen gas at high temperatures; and it appears that the Indian process combined the principle of both these methods. The antiquity of the Indian mode was proved by the present of thirty pounds weight of steel, made by Porus, to Alexander the Great; and the ignorance of the Western world was shown as well by this as by the fact that the arms of the warriors of ancient Europe were composed of alloys of copper and tin. The tools by which the Egyptian obelisk and temples of porphyry and syenite were cut, were undoubtedly made of Indian steel. Mr. Heath concluded with observing, that he did not think the Hindu process influenced the quality of the steel; but it enabled the manufacturer to accomplish with very imperfect means that which it would be hopeless for him to attempt by European processes.

SIR CHARLES LEMON'S MINING SCHOOL IN CORNWALL.

It is hardly necessary to repeat the observation that the proposed course of instruction is not undertaken with the view of teaching Mining, for that can only be acquired in the mine itself, and the best opportunities are already afforded in various and extensive works throughout the county. But with respect to those arts and sciences, which, from their close connexion with mining, are most valuable to a Cornishman, equal facilities do not abound, nor are they generally within the reach of that large class of mining agents, engineers, and others, who would be chiefly benefited by them. It is proposed experimentally to supply this deficiency; and to afford facilities for attaining useful scientific and practical knowledge in the midst of the Cornish mining district, on the following plan:—

The principal course will commence early in July, and will comprise separate series of lectures and examinations in Mathematics, Mechanics, Metallurgic Chemistry, and Mineralogy—a detailed programme of this course will be submitted to the public in due time. At present it is only necessary to point out by what steps the student may prepare himself to enter on these studies with the best effect.

Probably two classes will be formed, according to the attainments of the pupils. But, as the professors conducting this course can remain in the county only a few months, it is of the greatest importance that, as far as possible, the students should be prepared at once, to take their places in the higher class.

The subjects taught will comprise *Algebra*; the elements of *Geometry*, which forms the only basis on which an accurate knowledge of planning and drawing sections of mines or machinery can be obtained, and which is indispensable in the execution of many most important works connected with mining.

The Elements of Land and Mine Surveying will be studied with reference to general principles; and the students will also be required to assist in actual surveys, and will be instructed in the construction of *Geological plans and sections*.

RAILWAY SOCIETY.

A private meeting, very numerously attended by the deputations from most of the leading Railway Companies, was held on Saturday last, at the chambers of Messrs. Burke and Venables, in Parliament-street, for the purpose of considering the propriety of forming a society for promoting and advancing the scientific improvement of railways throughout the kingdom, and for protecting generally the interests of railway proprietors.

Mr. George Carr Glyn, the chairman of the London and Brighton and North Midland Railway Companies, was called to the chair, and opened the proceedings by adverting to the great and manifest importance of the proposed society, as affording a means of bringing the united experience and influence of the principal persons connected with railways to bear upon all questions which may arise respecting them.

The honourable chairman further alluded to the very great ignorance which exists among many, even at this day, on the subject of railways, and the consequent prejudices, which prevail against them, and pointed out the great advisability of having some regularly organized association which would be looked up to as an authority on all subjects in which their interests were involved.

The meeting was subsequently addressed by several other gentlemen present, who all concurred in the importance of the proposed association, and dwelt on the advisability of forming, at its outset, a collection of maps, reports, models, and other scientific and statistical details relating to railways, which should be accessible to the several members of the society, and which would in time become a most valuable and interesting museum of reference on matters connected with railways.

Some discussion took place as to the amount of the subscriptions, and the name to be given to the proposed association, viz. whether it should be called the "Railway Society," or the "Railway Institute," but eventually this, with all other matters of detail, was left to a committee of management formed of some of the directors of the principal railway companies present, who were empowered to add to their number, if they should see fit.

Resolutions, embodying the substance of the foregoing remarks, were unanimously passed, and the several persons present, having enrolled their names as the first members of the society, the meeting separated.

MEETINGS OF SCIENTIFIC SOCIETIES FOR APRIL.

Royal Society, Thursday, half-past eight, P. M., 11th, 18th, and 25th.
Society of Antiquaries, Thursday, eight, P. M., 11th, 18th, and 23th.
Institution of Civil Engineers, 25, Great George-street, West, Tuesday, eight, P. M., 23th, and 30th.
Royal Institute of British Architects, 16, Grosvenor-street, Monday, eight, P. M., 8th, and 22th.
Architectural Society, Tuesday, eight, P. M., 9th.
Society of Arts, every Wednesday, half-past seven, P. M., 9th.
Ditto, Illustration, Tuesday, eight, P. M., 9th.
Geological, Wednesday, half-past eight, P. M., 4th and 25th.
Royal Geographical, Monday, nine, P. M. 8th, and 29th.
Graphic, Wednesday, eight, P. M., 25th.

New Locomotive Engine.—We have received a letter from a friend in America calling our attention to a new locomotive engine calculated to ascend an inclined plane, a model of which he has seen. The following is a brief account of it, so far as the inventor will at present allow it to be made public; for it appears he had not procured a patent for it. It is described as a locomotive engine of eight or ten tons weight, cylinder 12 by 18 inches, of the ordinary construction. In ascending or descending inclined planes, the driving wheels are raised from the ordinary track, and the locomotive is partly sustained on small wheels (well represented by the ordinary hubs of a carriage) on raised rails each side of the track two feet high. The invention consists in a mode of gaining adhesion, which can be increased to any extent with very little increase of friction The power being transferred from the large driving wheels to small ones, the velocity will of course (in ascending) depend upon the steepness of the ascent, which will regulate the size of the small wheels. We calculate, according to Pambour, to ascend a plane of 200 feet rise in the mile, at the rate of four miles the hour, with 100 tons burden. The apparatus to gain the adhesion cannot add 300 dollars to the cost of the locomotive; it is never in action except when overcoming inclined planes; will last longer than the locomotive, is simple, easily managed, and not at all liable to get out of order. The expense of the raised rails will depend upon the materials used in their construction, which may be of wood or iron. Two hundred feet in the mile is the maximum of ascent recommended, but by reducing the velocity and load, 400 or more may be overcome. The apparatus is within the locomotive, which, with the raised rails, constitute all that is necessary to overcome the ascent. There will be no time lost in commencing the ascent.—*Scotsman.*

Blasting by the aid of Galvanism.—An experiment was made with complete success with one of Daniel's galvanic batteries, under the superintendence of Colonel Pasley, of the Royal Engineers, at half-past two o'clock last Saturday, off the gun-wharf, Chatham. 85lbs. of powder were exploded in about 10 fathoms of wather, the length of the wire conveying the electric fluid being 500 feet; it caused a most tremendous explosion. Three smaller ones were afterwards tried, but only one succeeded. There was a numerous assemblage of spectators. The Royal George, at Portsmouth, we understand, is to be blown up in a similar manner, and this experiment was preparatory to the attempt.—*Maidstone Journal.*

Iron Houses.—The efficiency of iron to the application of steam-vessels has been so successfully introduced, that we notice an elegant plan of a sea-coast cottage of that description hung up in the Tontine Coffee-room, which seems so admirably adapted that we have no doubt they will soon be in very general use. The plan referred to seems to have six rooms, kitchen, and laundry, and other conveniences, for the small sum of 250*l.*, or if a double house of fourteen rooms, 500*l.* This is not half the price of a common house with similar accommodation, and can be ready to possess in two months. The iron trade of this neighbourhood should each set down one by way of introducing them.—*Glasgow Chronicle.*

March 7.—*Caledonia Canal.*—Select committee appointed "with a view to consider and report to the House, what steps it is advisable to take with respect to the present state of the Caledonian Canal."

March 1.—*Irish Railways.*—Motion made, and question proposed, "That her Majesty be enabled to authorise Exchequer Bills to an amount not exceeding 2,500,000*l.*, to be made out by direction of the Lords Commissioners of the Treasury, and to be by them advanced for the construction of a railway or railways in Ireland, the sum so advanced being secured, and the interest and sinking fund to be secured on the profits of the works, the deficiency, if any, being provided for by an assessment, on the several districts through which such railway or railways may be carried, or what may be benefitted thereby."—Question put, Ayes 144, Noes 100.

LAW PROCEEDINGS.

PAVING ACT.

Marlborough-street.—A matter of some importance to paving boards and proprietors of land was argued on Saturday, 2d ult., before Mr. Conant and Mr. Dyer, the sitting magistrates.

Lady Montfort, the lessee of a mansion in Park-lane, appeared by counsel (Mr. Clarkson) to answer an information laid under Mr. A. Taylor's act, by the trustees of the parish of St. George, Hanover-square, for an alleged violation of the act, in breaking up the pavement to the length of eight inches, whereby her ladyship had incurred a penalty not exceeding 10*l.*

Mr. Clarkson said the question between the parties was one of great public importance. Lady Montfort, in order to have a magisterial decision on the point at issue, had caused to be taken up a portion of the pavement before the house to which she laid claim as private property, and as belonging to the site of the house leased to her.

Mr. Bodkin, on the part of the trustees, said that in 1831, Lady Montfort rebuilt the house, and at that time she applied to the paving board to open a grating before it, but she was refused. Since the refusal, in order to raise the present question, she had broken the ground, and the trustees in consequence had adopted the present proceedings.

Mr. Clarkson said it was true that Lady Montfort had applied to the pavement board for permission to open a grating, and had been refused. But her application was for 18 inches, an extent of ground which he admitted Lady Montfort could not claim. Lady Montfort, in the present instance, had broken the pavement to the extent of eight inches, which she was prepared to prove by her lease was part of the ground belonging to the house.

The lease was then produced, by which it appeared that the extent of the ground in feet and inches was specified. The present mansion occupied the entire space, with the exception of eight inches, which the parish authorities some time back had paved over.

Mr. Bodkin said the parish proved their right by paving the ground in 1831.

Mr. Conant asked who was the freeholder of the ground?

Mr. Clarkson said the freehold was vested in the Dean and Chapter of Westminster. It was true the parish had paved over the eight inches now claimed since 1831, but that act did not vest the proprietorship of the soil in the parish. What answer would it be to the freeholders, because the leaseholder had not chosen to take in the eight inches when rebuilding the house, that the parish had paved the place and taken the soil? Though the parish had paved the ground, the freeholder, he contended, could resume it when he pleased.

Mr. Bodkin said, if it were competent for a person to go back to old documents to prove that at one time a portion of ground belonged to him, what, for instance, was to hinder Lord Grosvenor from resorting to the same course with respect to his property, and to say to the parish, "I had this ground, and I will break up the pavement and carry out a portico in assertion of my rights?"

Mr. Conant said, as lord Grosvenor had been referred to in the way of illustration, he would carry the argument further. Suppose the parish chose to pave before his lordship's house, they might then set up a claim to the ground. This appeared somewhat of the nature of Lady Montfort's case.

Mr. Bodkin said, the question was very important, and the parties were anxious to have the matter reviewed in a solemn way by an appeal to the superior courts.

Mr, Conant said, he thought the trustees were bound to show on what grounds they paved the portion of land in dispute.

Mr. Cunningham, the late surveyor, was called, but he could state nothing more than that he had paved flush up to Lady Montfort's house, in compliance with the orders of the paving board. He could not say whether the eight inches now claimed did not form part of the ground claimed by the freeholder.

Mr. Conant said, the matter for the court to decide was not whether the ground was public or private property; the question was as to the jurisdiction of the act of Parliament, and whether the present proceeding was such an encroachment as subjected the party adjoining it to a penalty. It would have been very material had the surveyor been able to show the ground on which the trustees had ordered him to pave the place, or that the eight inches in question did not form a portion of the private freehold; but the surveyor could do no more than prove that for about eight years he had paved the disputed piece of ground. Now, the time during which the parish had paved the place was too short to give the parish a right to the soil, or to permit them to levy a penalty on an attempt being made to resume an alleged right; for if the parish could claim under such circumstances, then any one might have his property paved over by the parish, and be called upon to pay a penalty if he attempted to take up what the parish had laid down. With this view of the case he must dismiss the information.

STEAM NAVIGATION.

ERICSSON'S STEAM-BOAT PROPELLER.

The experimental iron steam-boat, Robert F. Stockton, constructed for testing Captain Ericsson's propeller, which we noticed some time since, being on the eve of departure for the United States, at the request of a number of scientific gentlemen who were desirous of witnessing her performance, the proprietor consented to another trial being made, and on Saturday, the 9th ultimo, a large party was invited for this purpose. Among those present were Major-General Sir John Burgoyne, Major Robe, of the Royal Engineers, Mr. James Terry, of Dublin, Messrs. Vignolles, Delafield, Reid, Napier, and Thomas; several Swedish naval officers; Captain Stockton, of the United States navy; Mr. Ogden, Consul of the United States at Liverpool; Mr. Young, an American civil engineer, &c., and about thirty other gentlemen were present, and the result of the trial gave universal satisfaction.

One of our correspondents having before described the construction of the new propeller, we will now more particularly direct attention to the effect produced during the trial, which appeared quite conclusive as to the success of this important improvement in steam-navigation. The distance from the West India south-dock, to a point opposite Woolwich church and back, measuring 37,000 feet, was passed in forty-five minutes precisely (twenty-one minutes with, and twenty-four minutes against the tide), the boat towing at the time a heavy city barge on the one side, a large wherry on the other, and another wherry astern. The speed of the engine being repeatedly timed by Mr. Young, it was found to average sixty-six revolutions per minute, or 2,970 during the forty-five minutes. The inventor demonstrated by accurate working drawings, that the spiral planes of the propeller are set at such an angle, that had the resistance of the water been perfect, the progress of the boat could only have been 132 feet at each revolution, or 39,204 feet during the time, instead of 37,000 actually performed, thus showing a loss of less than 6 per cent. Respecting the engines for working the propeller, it was observed, that they may be made much stronger and more compact than ordinary marine engines, in consequence of the power being applied directly to the shaft which works very near the bottom: this for sea-going vessels will be very important, and their original cost must be considerably reduced, as all the paraphernalia of shafts, wheels, wheel-guards, &c., will be dispensed with. We were struck with the great regularity of the motion, not the slightest jar being perceptible. The engines consist of two cylinders sixteen inches in diameter, with eighteen inches stroke, and are worked by steam, of a pressure varying from 35lb. to 55lb., to the square inch; their construction is extremely simple, and evinces a knowledge of steam machinery in the inventor which is calculated to give additional confidence in the success of his propeller in all the varieties of its application for canal, river, or ocean navigation.—*Times.*

Great Western Steam Ship.—A half-yearly general meeting of the proprietors was held in Prince's-street, Bristol, last week. Mr. Maze took the chair. Mr. Claxton read the report, which stated that the company's first ship had disproved all unfavourable auguries, and promptly rewarded the enterprise of the projectors. It was impossible to speak too highly of the qualities of the Great Western steam ship; after having run 35,000 nautical miles, and encountered 36 days of heavy gales, her seams required no caulking, and when she was docked she did not show a wrinkle in her copper. The average of her passages out was 15½ days, and home 13 days; the shortest passage out was 14½ days, and the shortest home 12½. About 1,00) passengers had gone in the ship. After alluding to the great expense necessary to combine speed, security, and enjoyment, it expressed a hope that through the liberality of the American Congress the duty of 2d. per bushel on coals would be given up, and thus a saving of nearly 1,000*l.* a-year would be effected. The company have decided on constructing their next vessel of iron, for which the preparations are far advanced. It appeared from the statement of accounts, that after paying 2,000*l.* for additions to the ship, and insurance to October next, 1,600*l.* for goods damaged in the hurricanes in October last, and upwards of 2,000*l.* being set apart for a reserve fund, there remained from the profits sufficient for a dividend of 5 per cent., making, with the former one of 4 per cent., 9 per cent. for the year. The report was unanimously adopted.

Launch of the Steamer Nicholai.—The ceremony of launching a splendid steam-vessel, named the Nicholai, took place on Saturday, the 16th ult., at Deptford, and, notwithstanding the unsettled state of the weather, attracted a large concourse of spectators. Among those present were Count Lubinski, Count Woronzow, several attachés of the Russian embassy, and other foreigners of distinction, Sir J. Brand, Captain Hayman, Captain Rowland, and many influential individuals connected with steam navigation. The Nicholai, which is 800 tons burden, has been built for the Emperor of Russia, after whom it has been named, and whose bust, said to be an admirable likeness, adorns her figure head. She is the largest steamer belonging to Russia, and intended to ply as a packet between Lubeck and St. Petersburgh. The Nicholai was built in four months after laying her keel. The vessel has been removed to Messrs. Seawards' establishment at Limehouse, for the purpose of having her engines put on board, which are to be of 240 horses power.

The Star, a new iron steam boat, intended for the passage trade between Shields and Newcastle, is reported to be a fine vessel, and draws only 23 inches water. She is the first iron steamer that has been launched from the banks of coaly Tyne.

A splendid little iron steam boat, of about 120 tons burthen, was on Monday, the 18th ultimo, launched from the iron works of Messrs. Summers, Groves, and Day, of Willbrook, near Southampton. She is built for the Lisbon Steam Navigation Company.

Steam Conveyance to America.—Government have entered into a contract for conveying the mails by large and powerful steam-vessels from Liverpool to Halifax, and thence by branch steamers to Boston, and in the summer to Quebec. The mercantile interests, not only in the North American colonies, but also in the United States, will be gratified to learn that, instead of a monthly communication, as formerly, steamers will now be despatched on the 1st and 15th of each month. The enterprising contractor has engaged with those able and scientific builders, Messrs. Wood, at Port Glasgow, to build three ships of 1,000 tons each, in which Mr. Robert Napier is to place engines of 400 horse power. From the past success of Messrs. Wood and Napier we doubt not, when these vessels are on their station, in April, 1840, they will be quite unrivalled; and, moreover, that the acute observation of "Sam Slick," that "the route *via* Halifax is the shortest way to New York," will be verified to demonstration.—*Glasgow Paper.*

Royal Naval Steam Service.—A splendid building, under the name of the "Engine Factory," is nearly completed in Woolwich dock-yard, with a large adjacent mast and timber pond, and a short canal cut for its communication with the great basin, with a cassoon and bridge to allow the steam-boats to be brought up alongside the factory, instead of being sent to the private manufacturers'. The boiler department is not yet, however, organised.

Mediterranean Steam Navigation.—The Austrian government continue to pay assiduous attention to this important branch, and, by a recent regulation, they have obviated the necessity of quarantine, by placing a sworn government officer of health on board each of their steamers,—a regulation which, it is to be hoped, will be adopted by other powers.

Brazilian Steam Navigation.—Two boats of the Brazilian Steam Navigation Company have arrived at Bahia, where they have excited the greatest sensation.

PROGRESS OF RAILWAYS.

EASTERN COUNTIES RAILWAY.

Report of the Engineer to the Directors.

Gentlemen,—In compliance with your instructions, I beg leave to submit the following report as to the state of the works, and the line, commencing at London and terminating at Springfield, a distance of thirty-one miles.

The whole of the London Viaduct, commencing at Farthing-street, within 300 feet of the terminus, has been let to four respectable contractors.

That portion between Devonshire-street and Dog-row, for a length of 31 chains, the whole of the foundations are laid, and the abutments and piers, are nearly all carried springing high, and several of the arches are turned.

The iron-work for the three bridges, Dog-row, Ann-street, and Globe-lane, is in a very forward state.

Nearly the whole of the portion from Dog-row to Winchester-street, a distance of 28 chains, is fenced off; several of the foundations are excavated, concrete forming, and brickwork for the piers and abutments commenced; large quantities of materials are on the ground. A further distance of 11 chains, extending to Bethnal Green Workhouse, is in possession of the contractor, and the house are being pulled down.

From Devonshire-street, eastward, to Angel-lane, at Stratford, the whole of the embankment is formed, with the exception of a small portion adjoining the Viaduct; also small portion at Tredegar-square, in the Fair Field at Old Ford, and east of the river Lea Bridge, in all amounting to less than 30,000 cubic yards on, which is being supplied from three different places, tendering the completion within a fortnight an easy task.

The embankment from the River Lea Bridge to Angel-lane is ballasted, and the permanent way laid.

Westward of Lea Bridge, a considerable portion is ballasted, and the laying of the permanent rails is commenced.

By means of a temporary stage or tipping frame this embankment containing upwards of 270,000 cubic yards, has been formed in less than nine months, nothwithstanding the winter season, and the more than ordinary difficulties presented by the yielding nature of the marsh lands over which it crosses, and which has occasioned a serious subsidence for a distance of nearly half a mile, and which would have rendered the formation of this embankment an extremely difficult, tardy, and expensive operation without the introduction of this useful, and I am happy to add, successful expedient, which has not only enabled us to deposit the large quantity of 231,000 cubic yards out of the above quantity over one tip in so short a space of time, but has been the means of completing the work much under the estimate.

It may be here gratifying to remark, that although the present subsidence of the embankment is within but 15 feet of one of the great reservoirs belonging to the East London Water Works Company, I have succeeded in preventing any injury to it.

The cutting from Angel-lane to the Ilford Valley is opened the whole distance, and the ballasting and permanent way formed, all but twenty chains. The embankment over the Ilford valley has been completed for more than six months; the ballasting and permanent way laid. The cutting east of the valley, with the exception of a small portion in Curtis's field, and the crossing of the Essex turnpike road, at the eighth mile-stone, is open to the tenth mile stone, and the permanent rail laid through Ilford for a distance of half a mile from the valley. About 10 chains east of this cutting, the gullet leading to the Chadwell cutting is open. The cutting from Chadwell to Whalebone-lane is completed, the road ballasted, and the permanent way laid.

The embankment at Whalebone-lane, extending towards Romford, is completed and the permanent way laid for a distance of 60 chains.

In order to expedite the formation of this embankment, a side cutting contiguous to the Barrack field at Romford has been opened. I therefore anticipate that the whole embankment up to Romford will be completed in less than six weeks.

Up to this point, the masonry commencing at the east end of the London Viaduct is complete, consisting of the numerous bridges over the rivers, and over and under the turnpike and occupation roads, amounting in all to forty-three, many of them of considerable magnitude, involving great expense in the construction of their foundations.

Continuing east of Romford, several other important works are completed.

In addition to these works, the station of Angel-lane, Stratford, with the engine-houses, coke-sheds, and water-tanks, and Whalebone-lane and Ilford, are nearly complete.

The whole of the line east of Romford, extending as far as Springfield, two miles from Chelmsford, being 31 miles from the terminus at London, is let to respectable contractors, with the exception of the summit cutting at Brentwood and Mountnessing, and the Shenfield and Mountnessing embankments.

The contracts between Romford and Brentwood have been let nearly six months, and the various cuttings, embankments, and other works at Hare-street, Hare-lodge, Gubbings, Brook-street, and Brentwood, are now in active progress, having been materially retarded by the weather.

The contract drawings from Springfield to Colchester are nearly ready for advertising.

In order to ensure the early completion of the works, six locomotive engines are employed day and night.

Six passenger engines will be ready within one month from the present time when also a sufficient number of first and second class carriages will completed.

A large supply of rails and chairs have been delivered, sufficient for upwards of sixteen miles of double line.

Plans and drawings for a complete London station, constructed in accordance with the experience hitherto gained, have been prepared, ready to proceed with the works when directed, for the entire opening of the line to Shoreditch.

I am Gentlemen, your obedient servant,

JOHN BRAITHWAITE.

BLACKWALL RAILWAY.

The Report of the Engineers to the Directors.

GENTLEMEN,—The whole of the Works on your line of Railway being now contracted for, with the condition that the execution shall be completed by the end of the present year, it affords us great satisfaction to report, that looking to the progress which has been made by Messrs. Webb since the 1st of October when they commenced their contract, and to the character and resources of the gentlemen who have contracted for the remaining portion of the line, we see not the least reason to fear that your expectations will be disappointed in respect of these arrangements.

On taking into account the united amount of these contracts, and adding thereto the cost of the permanent way, not included in them, we feel ourselves justified in stating our conviction, that the anticipated saving to be effected by the alteration of the width and levels of this railway will be fully borne out by the result.

The respective parties who are under engagements to furnish the engines for the working of the line, are actively employed in their construction; at the same time they are also preparing the large drum and spur wheels for winding the rope. We deemed it desirable to delay to the latest period (consistently with the early completion of the works) the specification necessary for the construction of this portion of the machinery, in order that we might avail ourselves of every improvement, which a continued and careful consideration of the subject could suggest.

We have unqualified satisfaction in being able to state, after going into extensive detail on the subject of working by stationary engines, which we have had an opportunity of doing in the course of various enquiries and calculations, that the annual cost of working by the proposed system, will be less by some thousands per annum than the amount assumed in our first report to you. We have now sufficient ground to satisfy our minds that the annual cost of working your line will not exceed £8,000 per annum.

The foundations for nearly one half of the proposed viaduct are now actually completed, and the piers are most of them finished to the springing height, many of the arches are completed, and the centres removed, and we calculate that, from this time, seven arches will be turned weekly in Messrs. Webb's contract, and in the other contracts in the same proportion.

The work, it must be borne in mind, has hitherto been done during the least favourable time of the year, and under one contractor only, but when the energies of two other contractors, with ample resources, shall come into operation, the works will be so accelerated as to leave no doubt of their being successfully terminated by the time specified.

We are, Gentlemen, your very obedient Servants,

(Signed) G. STEPHENSON,

London, 25th February, 1839. GEO. P. BIDDER.

CROYDON RAILWAY.

Report of the Engineer, to the Directors, read at the Half-yearly Meeting, held on the 5th ult.

GENTLEMEN,—Having received your instructions, that I should report to you the state of the works of the London and Croydon Railway at the present time, I have to report as follows:—

The stations at Croydon and Norwood may be considered complete, and fit for passenger traffic.

All the stations along the line are nearly finished, except the erection of two lodges, which will be constructed in a temporary manner for the opening of the line.

With the exception of the cutting at Forest Hill and the dressing of some slopes, all the earthwork along the line is completed; and on the Forest Hill cutting the east side is cut through with the exception of the slip near Owen's-bridge, and the west side remains to be bottomed out, and the slopes dressed down, for a distance of about 10 chains; on the west side of this length the greater portion of the slips occurred in the winter, when we had to encounter great difficulties, but since the weather has become drier, and means have been resorted to to prevent any further extension of the slips, the works have proceeded more rapidly, and the slopes have remained in the finished part in a perfectly substantial state; no slipping worth notice has occurred on any other part of the line.

The station and workshops at New Cross are on the point of completion, and the carriages are about to be delivered there.

The London station will be in a sufficiently forward state by the time the permanent rails are laid on the rest of the line.

All the bridges along the line except one occupation bridge are completed, and of this the arches are turned, and a fortnight's fine weather will enable the contractor to finish it.

The permanent road is being pushed on with all possible vigour consistent with sound workmanship and good drainage. There are employed in this department upwards of 300 men, with an adequate quantity of horses, drivers, locomotive engines, &c.

Of the permanent way there are laid,

6 miles 1 chain of single road complete;
1 .. 23 .. partly complete;
4 .. 75 .. double road ballasted and laid;

so that all required to complete the permanent way throughout will be,

5 miles 67 chains, or 10,282 yards of single line to lay;
2 ... 1 .. or 3,502 to ballast.

The quantity of earthwork remaining to be excavated in the Forest Hill contract, including extra slopes, slips, removal of spoil, clearing up bottom, &c., amounts to about 30,000 yards; but the opening of the road need not be delayed until the whole of this is removed, as more than two-thirds belong to the slopes and slips, not affecting the bottom, and will be moved after the completion of the permanent way.

I am, Gentlemen, your obedient servant,

JOSEPH GIBBS.

THAMES HAVEN DOCK AND RAILWAY.

Extract of Report read at the last Half-yearly Meeting.

Your Directors, at the half-yearly meeting in August last, reported that they had enter d into a contract for the construction of the Dock at Thames Haven; the works have in consequence been proceeded with, to the extent of 400,000 feet o excavation; the contractors have built cottages to house 200 men, and the further progress is only delayed until more land shall be in possession of the Company by an arrangement with the tenant, and the present meeting shall place it in their power to continue. The Directors would advise the shareholders to continue the operations at the Dock, as a valuable basis, and as the surest method of attaining the grand object of the undertaking.

The Directors have made several efforts to come to some definitive terms of agreement with the Directors of the Eastern Counties' Company, for toll; but as the amount demanded for passengers would prevent any traffic on the Thames Haven line, or any profit if carried; and as the Directors of the Eastern Counties' line have declined to make any immediate terms whatever for goods or heavy weights, as coals, &c., which must form a large portion of the traffic of the Thames Haven line; and as it is absolutely essential that a fixed plan should be arranged by which such articles can be secured for the Company; and as it also appears upon the report of your engineer, that two lines of rails upon the Eastern Counties' line will not admit of the anticipated traffic of the Thames Haven line with its own; and would if it could be managed at all, utterly preclude the possibility of slow speed trains, by which means alone a profit can be made by heavy goods, but at which a larger amount will be derived than from passengers; and as they feel also that the inconvenience of one line of road for two companies, places the company in a dependent, uncertain, and unpleasant position, at the will of persons who may be indisposed to them, or anxious to give greater facilities to other parties, which would cause an endless source of litigation and annoyance to the public. Under all the circumstances of the case, your Directors have considered it better to be prepared with, and adopt any integral and direct line into London. To this end your engineer has surveyed and laid down a line of road from Thames Haven to the Minories, where one of the best termini in the metropolis can be made—the position for all purposes being much superior to that of the Eastern Counties, particularly for the traffic on your line. The road is thereby shortened to 25½ miles, and the gradients are so good as to be for all working purposes almost a level. The advantage this would give for the carriage of great weights is highly beneficial, and will enable the Company to carry out the principle they have established of low fares, which, wherever they have been supported by good management, have proved so entirely successful.

MANCHESTER AND BIRMINGHAM RAILWAY.

Report of the Engineer to the Directors.

Gentlemen.—In accordance with your instructions, I submit the following report on the progress and state of the works. Those parts of the line which are contracted for and in progress extend from Fairfield-street, in Manchester, to the south side of Daw Bank, on the Cheshire side of the river Mersey, at Stockport. This distance is divided into five contracts, which are separately noticed as follows, viz.:—

Contract No. 1, or Fairfield-street Contract.—Commenced August 14th, 1838. Time of completion, eighteen months. This contract is 1,155 feet in length, and comprises the first portion of the viaduct by which the railway leaves the depôt in Manchester. It consists chiefly of arches of brickwork, varying in span from 30 to 45 feet, and of one cast-iron arch of 128 feet 9 inches span. The progress hitherto made it consistent with the work being completed within the specified time.

Contract No. 2, or Chancery-lane Contract.—Commenced August 14th, 1838. The time for completion is eighteen months. This contract is 2,136 feet in length and consists of the second portion of the viaduct by which the railway leaves the town of Manchester. The contractor has not yet had possession of all the land, but is expected to have it in the course of a few days hence, and the whole will be completed with ease in the specified time.

Contract No. 3, or Hyde Road Contract, is 1,900 feet, and comprehends the third or last portion of the viaduct issuing from the town of Manchester. It is not yet commenced, by reason of the obstacles which have hitherto prevented the company from obtaining possession of the land; but, as it is expected that the contractor will have possession in the course of a few days, such arrangements will be made as will ensure no delay arising from this unavoidable postponement of operations in this part of your works.

Contract No. 4, or Heaton Norris Contract, extends from the Hyde Road at the south end of No. 3 contract, to near the right bank of the river Mersey at the town of Stockport; its length is four miles twenty-six chains. It also includes the ballasting and laying of the permanent way upon contracts one, two, and three. It dates from September 11th, 1838, and the time of completion is 20 months. The heaviest work on this contract is a cutting of 409,000 cubic yards, the whole of which is to be carried to embankment; and 350,000 yards of this quantity are to be carried in one direction. About 80,000 yards have been already excavated. The contractor is proceeding actively and judiciously; on the 18th of this month, he will commence night work, and he is making such arrangements as will enable him to calculate upon completing the embankment to the end of the third contract by November next, when he will be ready for laying three miles of the permanent way; and there appears to be little doubt of his performing his contract in the specified time, namely, by May, 1840.

Contract No. 5, or Stockport Viaduct Contract, dates from November 18th, 1838. The time for completion is two years. It consists of a viaduct of 22 arches, of 63 feet span each. The first stone of this structure has been laid to-day, and the contractors are making arrangements for proceeding vigorously with their work.

Contract No. 6, or Congleton Viaduct Contract.—This work has just been let, and is to be completed in two years and a half. It consists of forty-two arches, each of sixty feet span. Preparations have commenced by throwing up clay for making about 15,000,000 bricks, during the present year.

This work is that which may be expected to require a longer time for execution than any other on the line; and therefore its being now commenced will facilitate the making of such arrangements in the future lettings, as will tend to bring all the other parts of the railway towards completion nearly at the same period.

I am, Gentlemen, your obedient servant,

Manchester, March 6th, 1839. GEORGE W. BUCK.

BRISTOL AND EXETER RAILWAY COMPANY.

Extract from a Report read at the General Half-yearly Meeting of this Company, held on Tuesday, the 5th ult., at Bristol.

The Directors have the satisfaction of stating, that although the season of the year since the autumnal half-yearly meeting has been necessarily unfavourable to the rapid progress of the works, they are, nevertheless, so far advanced as to warrant a confident hope that the great bulk of what remains to be done, in the construction of the line between Bristol and Bridgewater, will be finished in the course of the present year, and several portions of the line so far completed as to allow of the formation of the permanent way to be commenced before the end of this year, and the remainder proceeded with early in the spring of 1840.

The principal works are comprised in the two first contracts, chiefly at the western extremity of the Ashton-valley. In these extensive progress has been made; and although more might undoubtedly have been done by the contractor, yet it is equally true that the state of the works is such, that as the season advances a considerable force may be advantageously employed, and a very large quantity of work executed during the summer months.

For some distance beyond this point the work is so light as to insure its early completion without difficulty.

At Puriton some interruption has been caused by impediments in the purchase of land; but these difficulties being removed, the facilities in the execution of the work are such, as to preclude any possibility of further delay.

The numerous and urgent representations that have been received, in favour of an immediate prosecution of the works below Bridgewater, afford a gratifying proof of the increased and increasing extent to which the value of the undertaking is appreciated by the inhabitants of the Western Counties. With the sincere desire, however, to accede to the wishes of the shareholders resident in that district, with an unabated conviction of the magnitude and certainty of the advantages to be derived from the extension sought for, and with a fixed determination to adopt as speedily as possible every step that can conduce to the early continuation of the line to Exeter, the Directors are, nevertheless, persuaded that they will most satisfactorily discharge their duty by faithfully adhering to the resolution expressed in former reports, to make expenditure and receipt go hand in hand, by an early opening to Bridgewater.

The construction of the bridge now in progress over the river Parret, may be justly appealed to as the best evidence of their anxiety to reach Taunton; a town of very great importance, less than ten miles beyond the bridge, approached through a fertile and populous district, by a route almost level, and itself the focus of such an extensive traffic in passengers and merchandise, as must at once place the question of revenue beyond the reach of doubt, and enable the Company to complete the entire line to Exeter, without inconvenience to the shareholders.

EDINBURGH AND GLASGOW RAILWAY.

Extract from the Report read at the last Half-yearly Meeting, held at Glasgow.

Your Directors, at a very early period, turned their attention to the letting of the Contracts for the more important works on the line.

The Almond Valley Contract, which comprehends the heaviest work to be executed and which had, at the date of the last general meeting, been just advertised, was shortly afterwards let to Messrs. John Gibb and Son, of Aberdeen, whose long standing and high character, as contractors, afford the best security for its completion within the time prescribed by the Company's Engineer. Your Directors are happy to say, that the expense of this portion of the line, although it embraces the great stone viaduct over the Almond, of 48 arches of 50 feet span each, will, notwithstanding the recent rise in the price of masonry, little, if at all, exceed the proportional amount of the Parliamentary estimate. In consequence of the arrangements previously made with Mr. Hogg, of Newliston, your Directors were able to give Messrs. Gibb and Son immediate access to the ground at the Almond; and these parties have ever since been pushing forward their works with their usual promptitude and vigour. Notwithstanding the unfavourable season of the year, the contractors have already removed a considerable quantity of earth, and sunk two shafts in the Winchburgh Tunnel, and have founded one abutment and several piers of the viaduct on the Almond; they have also laid down a great deal of building material, so as to avail themselves of the earliest improvement of the weather in spring.

Your Directors, after completing the contract for the Almond Valley, next turned their attention to the contracts for the tunnels, &c., in the neighbourhood of Falkirk and of Glasgow. These were advertised to be let in four different lots, and although your Directors experienced difficulty, in two instances, in procuring Contractors, possessing sufficient capital and experience, they have now the satisfaction of reporting, that they are all let on favourable terms, and to parties, of whose ability to complete them, your Directors entertain no doubt.

Other contracts of smaller extent, but embracing 18 miles of the line, have been advertised, and for these your Directors expect there will be a keen competition, as many most respectable contractors have already intimated their desire to offer for them. Before the season is much further advanced, your Directors anticipate that upwards of 26 miles of the line will be let, and in course of execution: and they will proceed with as little delay as possible to have the working plans prepared, and the contracts let for the rest of the line.

Leeds and Bradford Railway.—The report of Messrs. Stephenson and Gooch has been presented to the Provisional Committee. From a copy which has been lying at the Exchange News Room during the last week, we make the following abstract. The engineers propose to make the terminus at the Leeds end upon a piece of vacant ground lying on the south side of Wellington-road, and between that road and the Whitehall-road. From thence the line will cross the river Aire and the Leeds and Liverpool canal, upon an embankment, a little to the west of the Suspension Bridge, then curving round to the west, it passes to the south of Castleton Lodge, and again crossing the canal, passes a little to the west of armly mills. It then takes the low ground between the canal and the river, and passes under the Kirkstall-road, by Kirkstall Bridge, and continuing between the canal and the river leaves Kirkstall Forge to the right. At New Laiths it crosses the river, and leaves New Laiths Grange to the north. It then proceeds to near Rawdon Low Mills, thence on the north side of the river to near Woodhouse Grove, which it leaves on the south and will cross the river and canal, and pass under Birk Hill, by a tunnel of about three quarters of a mile in length. It will then run parallel to and on the south side of the canal to Shipley, where crossing the branch canal it will enter the Bradford valley, and proceedin nearly a direct line to the town. The terminus and depot at Bradford will be in a field on the low side of the quarry of Messrs. Cousen and Thackray, and near to the works of Messrs. Haste and Sons. The length of the line will beabout thirteen miles, and no inclination on the main line will exceed twenty feet per mile. The estimated cost of laying down the railway is 400,000*l.*, exclusive of stations, depots, engines, which, together with all other necessary machinery, will require a further sum of 50,000*l.* Another important feature in the report is the formation of a junction line between the main line and the North Midland, which is intended to cross the turnpike-road near Wellington Bridge, and passing between Messrs. Marshall and Co.'s works and the village of Holbeck, and between Mr. Russell's pottery and the Toll-bar, and thence to the North Midland Railway, a little south of the Leeds pottery. This junction line, about one mile and three quarters in length, will enable passengers, &c. to pass on to the latter railway without the inconvenience and expense of changing conveyance.—*Bradford Observer.*

Preston and Longridge Railway.—We understand that Mr. Wilkie, the principal contractor upon this line of railway, has completed his works; and the Directors are now laying the permanent rails, so that, in all probability, the railway may be opened early in the summer. It is calculated that a saving of 2d. per cubic foot upon the carriage of ashler stone, and 1s. 6d. per ton upon walling stones from Longridge to Preston, will be effected by this means.—*Preston Chronicle.*

Newcastle and North Shields Railway.—The works on the line of the Newcastle and North Shields Railway are now rapidly drawing to a conclusion, and it is expected that the road will be opened to the public during the ensuing spring. Those stupendous erections, the great viaducts over the Ouseburn and Willington Deans, are on the point of completion, and are exciting, as might be expected, the attention and admiration of the neighbourhood and of all strangers. Two grander and more beautiful erections are certainly not to be found in this kingdom. The bridge over Willington Dean is now finished, and from its magnitude forms a most striking object in our local scenery. It is composed of seven arches each of 120 feet span, with two massy buttresses, and is in length 1060 feet. The height of the roadway of the main arch over the small stream which flows beneath is seventy-eight feet. The bridge over the Ouseburn Dean will be finished in a very few weeks. It is composed of five arches of 116 feet span, with two stone arches at each end, to throw the embankment from the breast of the hill. The height of the roadway of this bridge from the bed of the Ouseburn is 108 feet. It is a most magnificent structure, but its more confined situation causes it to be a less prominent object than that over Willington Dean. The public are daily taking more interest in this railroad, and are eagerly anticipating the increased accommodation and comfort it will afford them. The distance, it is confidently expected, will be accomplished within twenty minutes, and it is understood to be the intention of the Company to fix the rates for the conveyance of passengers at as low a point as circumstances will warrant.—*Newcastle Journal.*

York and North Midland Railway.—Since our last notice of the state of the works on this line, considerable advancement has been made. The men still continue to be employed day and night, and the excavation of the rampart is now completed. In addition to those employed in removing the earth, workmen had been busily employed in pulling down the wall that enclosed Messrs. Backhouse's garden. The foundations of the walls for the company's depots, near to the river, have been laid, and the bricklayers are busied in the building of those walls.—*Doncaster Chronicle.*

The London and Brighton Railway.—The works, both at Balcombe and at Clayton, have been stopped for several days, in consequence of the springs being out. There are from 50 to 60 feet of water in the Balcombe shaft, and from 20 to 30 feet in Clayton shaft. Indeed we have heard that a very grave doubt exists whether the line must not be altogether diverted, to avoid these dropsical hills.. A gentleman was recently down from London to view and inspect these spots, who declared that the symptoms were more formidable than those which were the cause of so much expense and delay on the Great Western line—*Brighton Guardian.* There is no truth whatever in the report that the operations on this grand work are likely to be formidably impeded by the springs. It will be recollected that Mr Rastrick noticed, in his report, the water at Balcombe and Clayton, and the mode of getting rid of it. When the headings are run, the water at Balcombe will fall into a brook to the south of the tunnel; that at Clayton will fall into the Clayton brook. Nothing can proceed more satisfactorily than the whole of the works on the line; and it is only from parties who are willing to cry down Brighton and its prosperity that a single word is heard against them.—*Brighton Gazette.*

Doncaster, North Midland, and Goole Railway.—We understand that the project for connecting Goole, Thorne, and Doncaster with the North Midland and the Sheffield and Rotherham Railways, has been received with high prospects of success. It will branch from the North Midland at Kilnhurst, and proceed through or close to Doncaster, extending inwards to the port of Goole. The preliminary steps have already been taken, and the line is now being surveyed under the skilful direction of Mr. Swanwick.—*Derby Reporter.*

Railway Swamped.—By an inundation of the Senne, the Brussels and Vilvorde Railway is covered with water six inches deep, and the travelling is interrupted.

Chester and Crewe Railway.—We learn that Messrs. Jackson and Bean, who completed a portion of the Birmingham and Derby Railway, have undertaken the Bunbury and Wardle contract, in length about ten miles, on the Chester and Crewe line.—*Chester Gazette.*

London and Brighton Railway.—Great exertions have been making lately in order to the completion of about three and a half miles of road on the Shoreham branch of this line. The late heavy rains, however, partially retarded the progress of the works, and the opening was in consequence postponed till Tuesday, 19th ultimo. The contractors will then re-commence active operations at the Hove cutting. The tunnel there will, we understand, be completed in the early part of July.—*Brighton paper.*

Railway Sanctuary.—As the constable of Milford was employed in conveying a man employed on the railway to gaol, on a charge of felony, he managed to slip from the officer, and descended into the Claycroft tunnel, in which he could not be found. The fellow got into a cart, covered himself with earth and rubbish, and was drawn out of the tunnel without being perceived, and made his escape.—*Derby Mercury.*

Breaking in of the Hanwell-Bridge of the Great Western Railway, and Loss of Life.—(From a Correspondent.)—Considerable alarm prevailed on Monday, the 18th ultimo, about 9 o'clock, on the line of the Great Western Railway, to the passengers who were coming to town in the train drawn by the Vulcan engine. On the arrival of the train at the viaduct-bridge which passes over the high road at Hanwell, they were thrown into the utmost consternation by hearing a report resembling that of a heavy cannon, which was supposed to be occasioned by the bridge over which they were in the act of crossing having given way. On making an examination, it was found this supposition was in a great measure correct, as one of its principal supporters, consisting of an iron beam of great dimensions, extending from one pillar of the bridge to the other, had snapped in half, carrying with it in its descent a vast quantity of the material of which the bridge was composed, leaving an open space under a portion of the line. On the next train coming up great delay was occasioned, in consequence of the apprehension that if it passed over the rails would give way, but from the care of the engineers and others, such a result did not take place. Immediate steps were taken to repair the damage, and several of the workmen were employed to shore it up. Whilst so engaged, a massive piece of timber fell from the upper part of the bridge upon one of them, and almost immediately killed him.—*Times.*

ENGINEERING WORKS.

NEW HOUSES OF PARLIAMENT.

The works connected with the embankment for the new Houses are probably the most extensive hydraulic works now in progress, and the coffer-dam is certainly unequalled; drawings and descriptions both of the coffer-dam and river wall were given in our first volume, and we shall now briefly describe what has been done up to the present time.

The coffer dam and other works were contracted for by Messrs. Lee, to be executed under the direction of Messrs. Walker and Burges, Engineers, and Charles Barry, Esq., Architect. The coffer-dam was commenced in the month of October, 1837, and is constructed nearly similar to the drawings and specification before given by us in Vol. I., page 31, with the addition of horizontal struts of whole timber at the back of the brace piles, B, fig. 1 and 2, and abutting against other piles driven just within the inner edge of the foundation of the wall. Considering the great extent of the dam it stands remarkably firm, and is tolerably free from leakage; it was finished on the 24th day of December last, when it was closed, and operations commenced within. For the purpose of pumping out the water, a 10-horse power steam-engine was erected, which is kept at work night and day; at the present time, the water is easily kept under by the aid of two 18-inch pumps, each working 14 three-feet strokes per minute; since the closing of the dam the whole of the silt or mud lying at the bottom of the river within the enclosure has been removed, leaving a fine bed of gravel over the whole surface; the gravel has been excavated for the foundations of the river wall, and nearly the whole of the foundations laid, and the sheet piling protecting the footings completed, likewise a considerable portion of the brickwork to the backing is commenced. The granite intended for the curvilinear facing is in an advanced state, a very large portion of it being already prepared and ready for setting. Too much praise cannot be bestowed on all parties for the activity with which the works have been conducted within the last two months; before another four months elapse, we hope that we shall be able to announce the river wall is completed, and the new buildings ready to be commenced.

The first stone of the foundation was laid on the 5th ultimo, without any ceremony.

WESTMINSTER BRIDGE.

We before noticed a commencement of the works for the repair of Westminster Bridge, in a former number; a dam has since been completed round two of the piers on the Westminster side, and a beginning made with the piling round them.

The great extent of the coffre dam (being no less than 500 feet in circumference), as also the difficulty experienced in driving the piles through a hard crust of gravel which overlays the clay at this place, and the care that must have been taken in doing the work, by so effectually shutting out the water, makes it appear to us truly astonishing that so much has been done in the short period of eight months, especially as all works of this nature depend so very much upon the weather and tides.

Great credit is due to the parties in charge of the work; and, if we may judge from the earnest manner in which they are proceeding, the public will have no cause again to complain of the tardy progress which hitherto marked everything connected with this bridge.

Neither can we omit to state, that upon our late visit, the gratification we experienced in witnessing the very dry state of the work, and although the level at which they are now proceeding is several feet below the bed of the river, there was not the slightest leakage; and we understand that the same has been the case since the completion of the dam.

The plan of operation for protecting the foundation of the piers, from being undermined by the wash of the river, is, by surrounding the caisson upon which the pier is built with sheet-piling, driven as close as it is possible to bring wood and wood together. The piles are driven fourteen feet into the solid ground below the bottom of the stonework; they are twelve inches thick, and the space between the pier and the piles is afterwards filled in solid with concrete, upon which masonry of square stones of large dimensions is laid, the top of the piles being dressed off to a fair and uniform line, and further secured with a strong band or waling of timber, encircling the whole tie, which is held in its place by iron caisson bars, firmly fixed to the main timbers of the caisson.

By this plan very little obstruction will be offered to the current, should any further increase of depth in the river take place, and from what we saw of the care taken to make the joints close, there will not be, in our opinion, the slighest apprehension for the safety of the bridge, should the river deepen three times as much as it has since the removal of London Bridge—a circumstance very unlikely to happen.

In comparing this method of work with endeavouring to accomplish the same object by diving bells (which was the plan till lately followed at this bridge), there cannot be a question which is the best; in one all is done in the dark, or otherwise hid from view; while in the other it is seen as the work progresses; in truth, the last is the only proper course.

THAMES TUNNEL.

Extract from the Report of the Directors at the last General Meeting, held at the London Tavern, 5th March, 1838.

The plan upon which the works have been carried forward consisted of three principal features, viz.:—

1st.—To divert the Navigation from that part of the River immediately over the Mining operations.

2dly.—To gain the command of that part of the River, without interruption, and to be thus enabled to load and cover its bed, both over the Works in progress and in advance of them; and to compress this artificial bed, directly over the Shield, by grounding upon it, at every fall of the tide, a vessel, when ballasted, of about 900 tons burthen.—And,

3dly.—To make alterations in the auxiliary parts of the Shield, still further to add to its security and power.

The brickwork of the Tunnel has been advanced, since the last Meeting, 90 feet, and is now within 60* feet of low water mark; and if the same rate of progress continues, which there is every reason to expect, low water mark will be reached in the course of the autumn.

It will be clear to those who are best acquainted with the work, that when this is accomplished the most hazardous portion of the Tunnel will be completed; and that however novel, and even bold, the work which then remains to be dene, in order to realise the original design, yet its complation becomes comparatively safe and easy, and calculable within a reasonable time.

* Since this Report was read to the General Meeting, Ten feet have been excavated the distance to low water is therefore only 50 feet.

Suspension Bridges.—The largest suspension bridge in this country is that across the Menai Strait, with a span of 560 feet; the next in point of size, is that at Montrose, which is 432 feet in span; we have been much gratified by the inspection of a report and plan of a third which will rival these stupendous works of art, both in magnitude and importance; for while they have but one span each, of the above dimensions, that to which we are alluding projected by that able engineer Mr. J. M. Rendel, will have two of 450 feet each, and a whole length (with the side openings) between the abutments, of 1126 feet. The site of the proposed bridge, is at Newnham, on the Severn in Gloucestershire, where there is at present a ferry, which has the great inconvenience of being entirely navigable only half an hour before and after high water. The great advantages of such a work will be materially felt in the adjacent country, by the coal and other mines of Dean Forest, becoming easier of access, thereby producing a considerable reduction of price, besides the convenience it will secure of a direct route across the Severn to the southward of Gloucester. The various drawings by which the proposed bridge is illustrated are admirably executed, and convey both in point of topographical, geological, and perspective detail, as complete an idea of this magnificent proposed work and its locality as can be expressed by the artist on paper.—*Nautical Magazine.*

The Wreck of the Royal George.—The experiment of blowing up the wreck of the Royal George, at Spithead, by means of 13-inch shells, placed as far into her in different parts as the divers can manage it. To prevent accident to any boat, the explosion will be effected by the rising of the tide operating on a buoy attached to the shells by a log-line.

Steam Dock-yards.—In bringing in the navy estimates, Mr. C. Wood stated, that the government had laid in ample stores—had added one-third to the dock-yards—and had made preparations at Deptford, Woolwich, Portsmouth, and Plymouth.

Overland Indian Mails.—The contract for a carriage conveyance over the desert between Suez and Cairo has been taken by Messrs. Hill and Co., and by the 17th of January, there was to be a carriage for the conveyance of passengers from Cairo to Suez, between which the distance is 90 miles, and the time is about 24 hours.

NEW PATENTS.

LIST OF ENGLISH PATENTS GRANTED BETWEEN THE 23rd FEBRUARY, AND THE 27th MARCH, 1839.

George Augustus Kollman, of the Friary, St. James's Palace, Professor of Music, for "Certain Improvements in the Mechanism, and general Construction of Piano-fortes, being an extension of former letters patent for the term of seven years."—23rd February.

Charles Louis Stanislas Baron Heurteloupp, of Queen Ann-street, for "Certain Improvements in Fire-arms, and in the Balls to be used therewith."—23rd February; 6 months to specify.

Thomas Pratt, of South Hylton, Durham, Mechanic, for "An Improved Capstan and Winch for Purchasing or Raising Ship's Anchors, without the application of a Messenger, in which there is no Fleeting or Surging, or for drawing or working of Coals or other articles, and things out of Coal or other Mines, and also for the drawing and working on Railroads, by drawing Pulleys with Flat or Round Ropes."—23rd February; 6 months.

James Russell, of Handsworth, in the county of Stafford, for "Certain Improvements in Manufacturing Tubes for Gas and other purposes, being an extension for the term of six years, granted to Cornelius Whitehouse."—26th February.

Moses Poole, of Lincoln's Inn, Gentleman, for "Improvements in constructing and applying Boxes to Wheels."—28th February; 6 months.

Moses Poole, of Lincoln's Inn, Gentleman, for "Certain Improvements in Tanning."—28th February; 6 months.

John Leigh, of Manchester, Surgeon, for "An improved Mode of obtaining Carbonate of Lead, commonly called White Lead."—28th February; 6 months.

Richard Whytock, of Edinburgh, Manufacturer, and George Chine, of the same place, Colour Maker, for "Further Improvements in the Process and Apparatus for the Production of Regular Figures or Patterns in Carpets and other Fabrics, in relation to which a patent was granted to the said Richard Whytock, on the 8th September, 1832, and generally in the mode of producing Party Colours on Yarns or Threads, of Worsted, Cotton, Silk, and other fibrous Substances."—1st March; 6 months.

Moritz Platow, of Poland-street, Oxford-street, Engineer, for "Improvements in Pumps or Engines for raising or forcing Liquids."—6th March; 6 months.

John Dickson, of Brook street, Holborn, Engineer, for "Certain Improvements in Rotatory Steam-Engines."—6th March; 6 months.

Auguste Victor Joseph Baron D'Asda, of Millman-street, Bedford Row, for "Improvements in producing or affording Light, which he denominates a Solar Light."—6th March; 6 months.

Walter Hancock, of Stratford, Essex, Engineer, for "Certain Improvements in Steam-boilers and Condensers."—6th March; 6 months.

George Robert D'Harcourt, of Howland-street, Fitzroy-square, gentleman, for "Certain improved artificial Granite, Stone, Marble, or Concrete, in which said invention neither Asphaltic nor Bituminous Substances are used."—6th March; 6 months.

Wm. Vickers, of Firshill, Sheffield, Merchant, for "A Mode of obtaining Tractive Power from Carriage-wheels under certain circumstances."—6th March; 6 months.

John Clark, of Upper Thames-street, London, Engineer, for "A New or Improved Form or Construction of a Leg and Foot for propelling Carriages on Rail or Common Roads, and a new Combination or Arrangement of Machinery for Locomotive Carriages, by means whereof the weight of the Load to be carried is rendered applicable as a part of the Power for moving or propelling the Carriage on which it is supported or rests."—6th March; 6 months.

Charles Schayhault, of Cornhill, London, Gentleman, for "An improved Method of Smelting Copper Ore."—6th March; 6 months.

Orlando Jones, of Rotherfield-street, Islington, Accountant, for "Improvements in the Manufacture of Starch, and the converting of the Refuse arising in or from such Manufacture to divers useful purposes."—6th March; 6 months.

George Holworthy Palmer, of Surrey-square, Old Kent-road, Civil Engineer, and George Bertie Paterson, of Hoxton, Engineer, for "Certain Improvements in Gas Meters."—6th March; 6 months.

Thomas Horton, of Prince's End, Stafford, Boiler-maker, and Thomas Smith, of Horseley Heath, in the same county, Mine Agent, for "Certain Improvements in the making or constructing of Chains for Pits, Shafts, Mines, or other purposes."—6th March; 6 months.

Edward Ford, of Liverpool, Builder, for "Certain Improvements in conducting the Manufacture of Salt Cake, or Sulphate of Soda or Hydrochloric, or other Acids and Alkalies, or other Chemical Processes, wherein Deleterious Vapours are given off, and in the Erection of Furnaces and Works connected therewith."—8th March; 6 months.

Josias Christopher Gamble, of St. Helen's, Lancaster, Manufacturing Chemist, for "Improvements in Apparatus for the Manufacture of Sulphate of Soda, Muriatic Acid, Chlorine and Chlorides."—14th March; 4 months.

Elisha Haydon Collier, late of Boston, in America, but now of Globe Dock Factory, Rotherhithe, Civil Engineer, for "Improved Machinery for Manufacturing Nails."—14th March; 6 months.

Christopher Nickels, of York-road, Lambeth, Manufacturer, for "Improvement in the Modes of Manufacturing of Fabrics from Linen, Woollen, Silk, and other Fibrous Materials."—15th March; 6 months.

Richard Lamb, of David-street, Southwark, Gentleman, for "Improvements in Apparatus for supplying Atmospheric Air in the production of Light and Heat."—16th March; 6 months.

Alexander Francis Campbell, of Great Plumstead, Norfolk, Esquire, and Charles White, of Norwich, Mechanic, for "Certain Improvements in Ploughs."—18th March; 6 months.

Thomas Henry Ryland, of Birmingham, Screw Manufacturer, for an "Improved Manufacture of Screws for Wood, in Iron, Brass, Copper, or any mixed Metals, commonly known as Wood Screws."—18th March; 6 months.

John Ruthven, and Morris West Ruthven, of Edinburgh, Civil Engineers, for "Improvements in Boilers for generating Steam, economizing Fuel, and propelling Vessels by Steam or other Power, and ventilating Vessels, and which may be applied to Mines and Buildings."—20th March; 6 months.

Edward Law, of Downham-road, Kingsland, Gentleman, for "Certain Improvements in evaporating Sea Water, and other Fluids, and in the Manufacture of Salt."—20th March; 6 months.

Joseph Amesbury, of Burton-crescent, Surgeon, for "Certain Apparatus for the support of the Human Body." 20th March; 6 months.

Andrew Smith, of Princes-street, Leicester-square, Engineer, for "Certain Improvements in the Manufacture of Ropes for Cables, and other purposes to which Ropes are applicable."—20th March; 6 months.

George Nelson, of Milverton, in the County of Warwick, Chemist, for a "New or improved Method, or new or improved Methods ot preparing Gelatine, which has the Properties of, or resembles Glue."—23rd March; 6 months.

Fisher Salter, of Hallingsbury, Sussex, Farmer, for an "Improved Machine for winnowing and dressing Corn and other Grain."—23rd March; 6 months.

Edmund Butler Rowley, of Manchester, Surgeon, for "An improved Steam-engine, applicable to Locomotive, Marine, and Stationary Purposes."—26th March; 6 months.

Richard Roberts, of Manchester, Engineer, for "An Improvement or certain Improvements of, in, or applicable to the Mule Billy Jenny Stretching-frame, or any Machine or Machines, however designated or named, used in spinning Cotton, Wool, or other Fibrous Substances, and in which either the Spindles recede from, and approach the Rollers, or other Deliverers of the said fibrous Substances, or in which such Rollers or deliverers recede from, and approach the Spindles, being an extension of former letters patent for the term of seven years."—26th March.

Joseph Leese, Junior, of Manchester, Calico Printer, for "Certain Improvements in the Art of Printing Calicoes, Muslins, and other Woven Fabrics, and in certain Processes connected therewith."—26th March; 6 months.

Henry Montague Grover, of Boveney in the county of Buckingham, Clerk, for "Improvements in Brewing, by the Use of a Material not hitherto so used."—26th March; 6 months.

Elisha Hale, of the United States of America, now of Leadenhall-street, in the city of London, for "Improvements in Umbrellas and Parasols."—27th March; 6 months.

William Newton, of 66, Chancery-lane, in the county of Middlesex, Civil Engineer, for "Certain Improved Machinery for cutting and removing Earth, which Machinery is applicable to the digging of Canals, and the levelling of Ground for Railroads, or ordinary Roads, and similar Earth Works."—27th March; 6 months.

MISCELLANEA.

Fire at Rome.—A letter from Rome of the 8th of February, states that on that day the Palace occupied by Count de Lutzen, the Austrian Ambassador, was almost entirely destroyed by fire.

Bishop Heber's Statue.—The statue of Bishop Heber has arrived safely at Calcutta, and has been deposited in the Cathedral.—*India Gazette.*

St. Germain Railway.—This railway has declared a dividend for the year of seven and half per cent.—*Galignani's Messenger.*

Indian Silver Mines.—Capt. Drummond and an experienced miner have been deputed to the district in the Himmalaya (the immediate range between the D'Hauli and the Gori) where silver is said to exist, to ascertain the fact.—*Asiatic Journal.*

Louvre Exhibition.—The exhibition of the works of living artists opened on the 2nd March, with about 3000 works from 1500 artists.

Danube Canal.—An article dated Bucharest, Jan. 18, repeats that the project for uniting by a canal the Danube and the Black Sea, will be carried into execution in the course of next spring, in virtue of an agreement between England, Austria, and Turkey.—*Times.*

Kilcooley Abbey.—The fine old Gothic mansion of Kilcooley was consumed to ashes last month. It was insured for £13,000.—*Kilkenny Journal.*

Egyptian Antiquities.—The Egyptian government have appointed a board for the preservation of the national antiquities.

Horticultural Society.—The Horticultural Society are now erecting a grand conservatory at Chiswick on a very large scale.

London and Westminster Bank.—The cost of the buildings and fittings is about £60,000.

ERRATA.

In our last number, page 92, column 1, line 30 from the bottom, for "as the effective pressure, and inversely as the density," read "as the *square root of the* effective pressure, and inversely as the *square root of the* density."

Page 93, column 1, line 16 from the bottom, for "will be greater," &c., read "will increase with the elastic force of the steam admitted into the cylinder in a higher ratio than if the elastic force of steam were proportional to its density."

Page 98, column 2, line 3 after engravings, for $G = H\frac{AB}{2}$ read $CH = \frac{AB}{2}$

Page 104, column 2, line 2 after the table, for "sketched, read "stretched."

Page 106, column 2, line 2 of 3rd paragraph, for "hydraulic lime," read "concrete."

Page 116, column 2, line 1, Statue to Mr. Stephenson, for "Robert," read "George."

Page 116, column 2, line 9, Eastern Counties Railway, for "200 yards per day, read "2,000 yards per day."

TO CORRESPONDENTS.

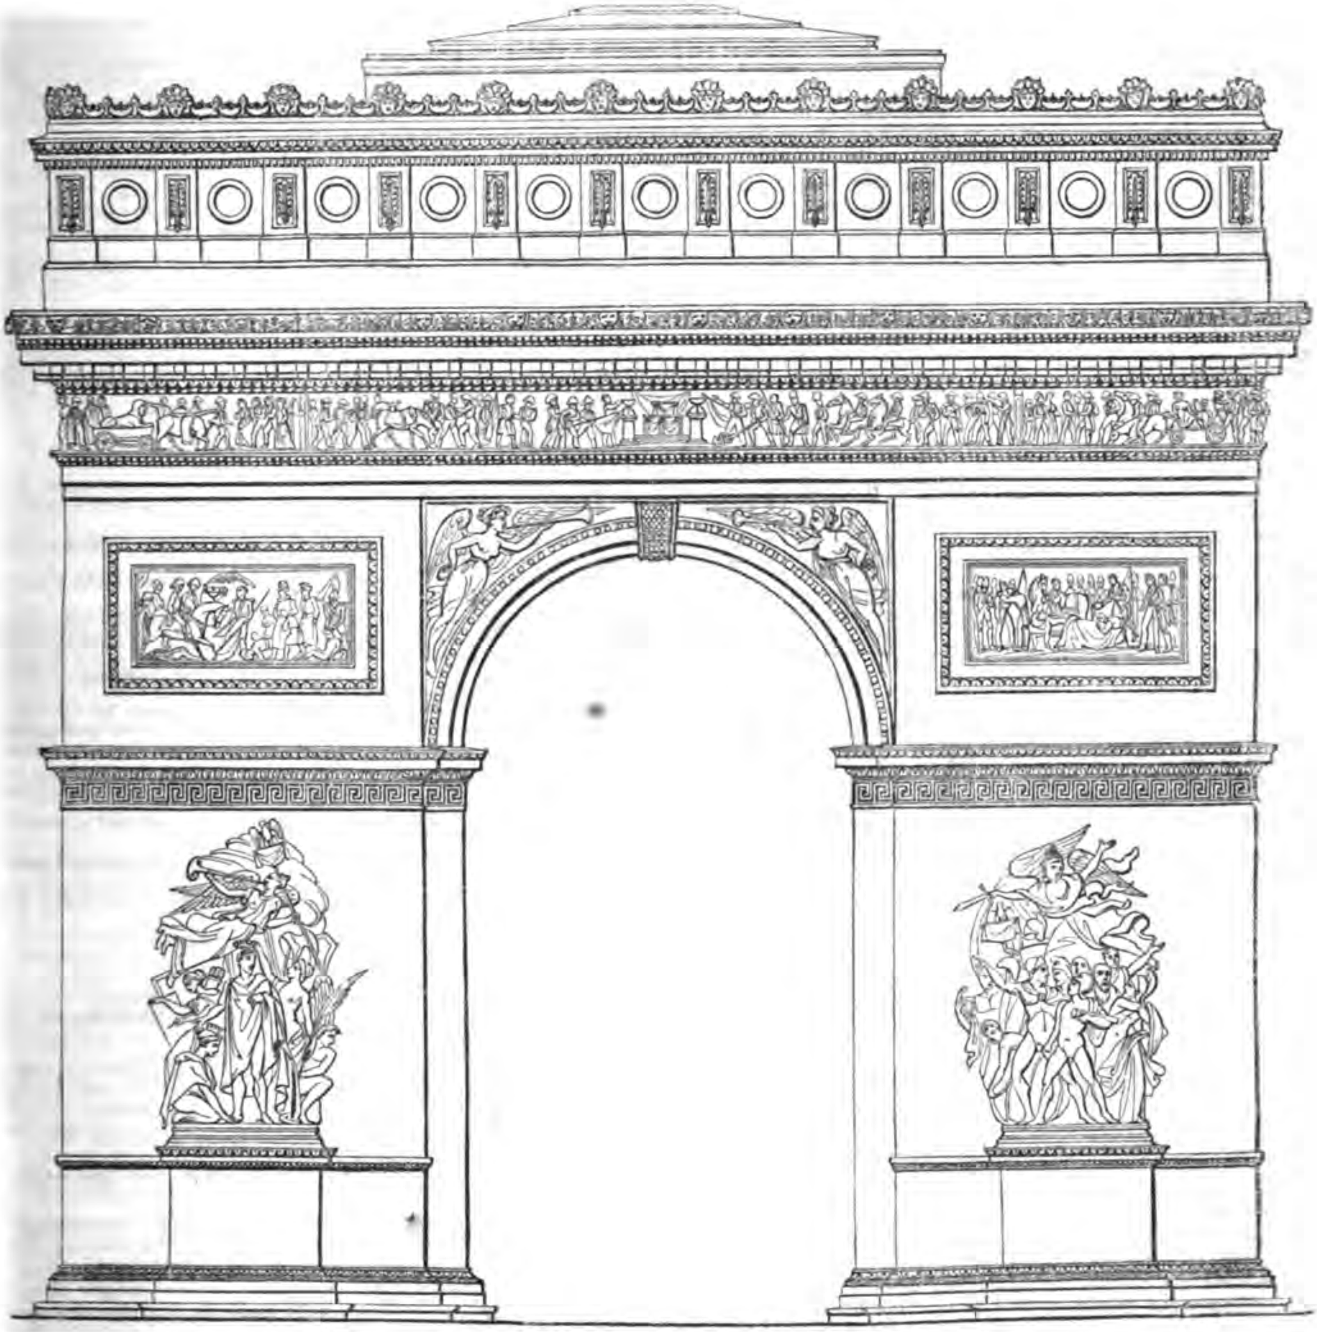
We have been obliged to postpone some of our communications and reviews until next month. We shall feel obliged to correspondents who may send drawings accompanying their communications, that they forward them early in the month.

We must apologise to our architectural friends for a deficiency of engravings connected with architecture. We intended to have given the drawings of the "Arc de l'Etoile," but in consequence of the considerable work in them, our wood engraver could not have them ready for the present number. They will be given in our next.

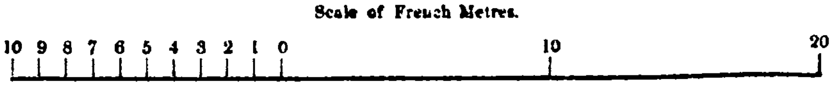
We shall feel obliged to our country correspondents if they will forward us any account of works in progress, or any newspaper containing articles connected with the objects of our Journal.

ARC DE L'ETOILE,

AT PARIS.

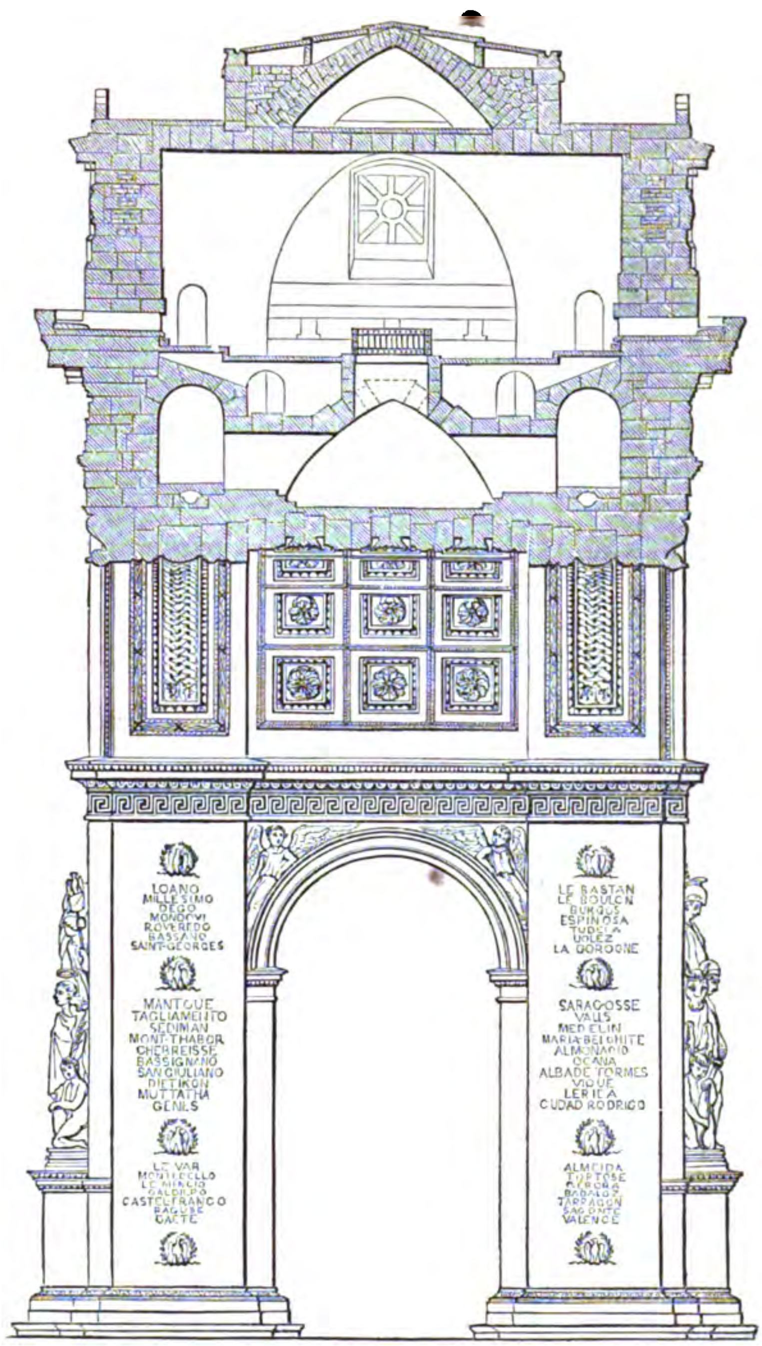


Scale of French Metres.



NOTE.—A French Metre is equal to 3·2809 Feet, or 3 Feet $3\frac{3}{8}$ Inches.

Fig. 2.—SECTION THROUGH THE CENTRE OF THE ARCHWAY.



THE ARC DE L'ETOILE, AT PARIS.

Between the commencement and the completion of this stupendous monumental structure, just thirty years elapsed—in the course of which memorable period, the Napoleon dynasty crumbled away with a celerity equal to that of its rise. Of the many designs for it submitted to the then government, those of Raymond and of Chalgrin obtained the preference. That by the former of these architects, proposed twelve coupled Corinthian columns on each of the sides, supporting a magnificent entablature, on which would have been as many statues symbollical of the different cities that had been taken by the French, and between these, bas-reliefs of the chief victories. The interior would have been divided into four masses on its plan, by the principal archway or vaulting being intersected by the transverse one; and the design further proposed that there should be seven halls in the upper part of the structure; viz., three smaller ones on each side, and a larger one in the direction of the principal arch.

Chalgrin's plan was much more simple, though it resembled the other in its general disposition; namely, in having two intersecting vaults, and consequently an arch on each of its four faces.

Even before it was decided which of the two designs should be ultimately adopted, preparations were made for carrying one or other of them into execution, and the first stone was laid August 15th, 1806. The foundations, which are 8 metres in depth, and 28 in breadth (or a fraction more than 26 and 91 English feet, respectively) and are formed of blocks of Cyclopean masonry, were already far advanced when Raymond, whose leading ideas it had been determined to adopt, resolved rather to have nothing to do with the work, than consent to the alterations it was proposed to make in his designs. He accordingly gave up his appointment as architect, in 1809; nor did he long survive the chagrin he felt on the occasion.

Chalgrin, hitherto only adjunct to the principal architect, now proceeded with the work according to his own ideas, and with such

Fig. 3.—The Ground Plan of one of the Piers.

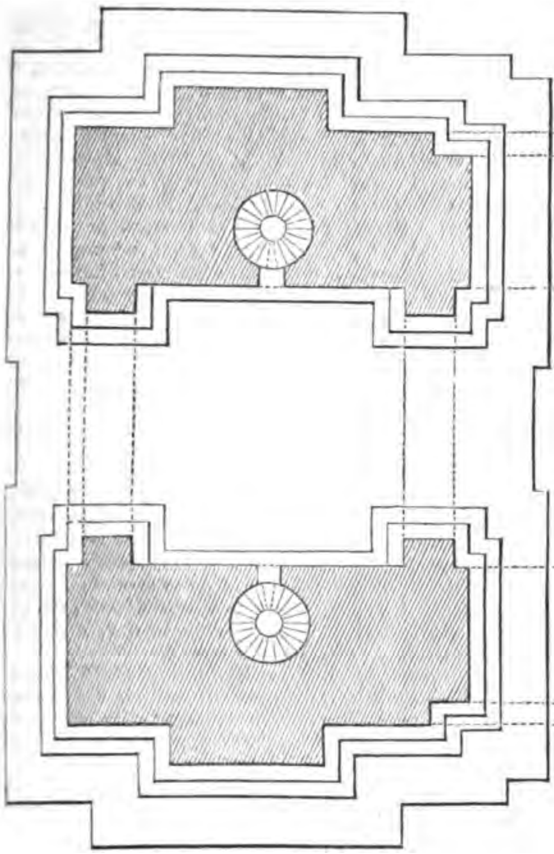


Fig. 4.—Half the Plan of Upper Story.

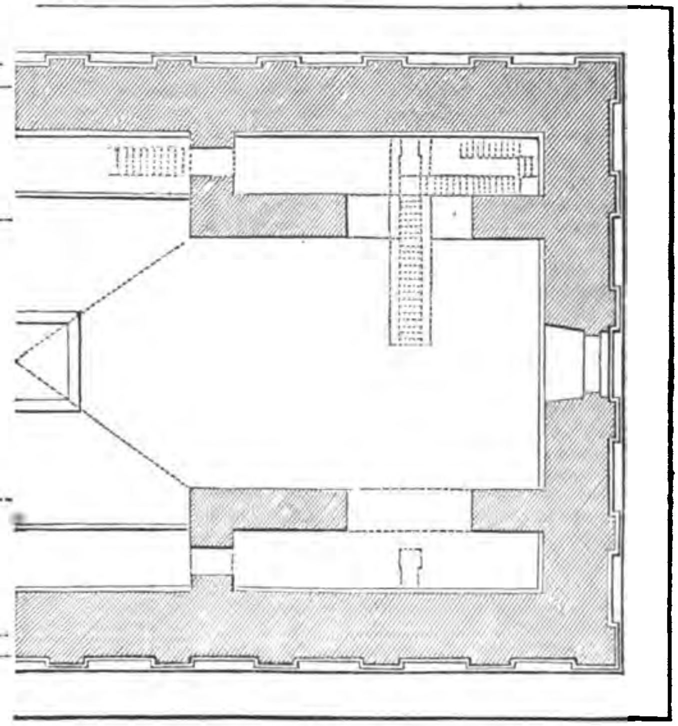


alacrity, that they had reached the height of more than twenty feet above the ground, when, in consequence of Napoleon's union with Maria Louisa, he was commanded to make some alterations in his designs with regard to the subjects of some of the reliefs, &c., but without interfering with the general idea for the monument. On Maria Louisa's entry into Paris, it was temporarily completed by a framework of timber raised upon it, covered with canvass, painted to resemble the decorations; and on this impromptu construction being removed, the works were prosecuted with all possible dispatch. Chalgrin, however, died in January, 1811, and was succeeded by Goust, who continued the edifice conformably with the designs of his predecessor, till 1814, at which time it had been carried up as far as the imposts of the arch. Then came the reverse, whose history may be summed up in the four disastrous words—Moscow, Elba, Waterloo, St. Helena.

After a pause of nine years, it was resolved in 1823 to proceed afresh with the work, but to convert it into a monument of the Duc d'Angouleme's Spanish campaign; and among the alterations in consequence proposed, it was considered expedient to remove the pedestals on each side of the arch to the centre of the piers. Accordingly, both Goust and Huyot offered plans for that purpose; and Huyot's was the one accepted by the committee, consisting of Tournon, Hericourt de Thury, Quatremère de Quincy, and Percier. This was, however, afterwards set aside, and Goust was ordered to proceed according to Chalgrin's plan. But in 1825 he was superseded by Huyot, and he had carried up the building as far as the attic, which he intended to be decorated with thirty statues on lofty pedestals, connected by an open balustrade; when the political events of 1830 interfered, and Louis Philippe ordered that the monument should record all the exploits of the French armies, from 1792 to 1815. Huyot was dismissed, and Blouet, his successor, completed the monument as it now exists. But Chalgrin's idea, which he recommended should be carried into execution, and according to which the whole would have been surmounted by a figure of Victory, in a car drawn by six horses, has not been realised.

Although the reliefs and other sculptures are in themselves the most important features in the monument, which, independently of such decoration, and its colossal vastness, has nothing particularly striking in its design, we shall not enumerate their several subjects, which would after all be a mere catalogue of names. In regard to them, therefore, we will merely state that M. Thiery, a French architect, is engaged upon a large descriptive monograph, in which all the details and ornaments will be fully exhibited together with the constructive details, and the changes that were made from time to time in the works. We must not, however, omit to specify its principal dimensions; which, for the sake of greater convenience, we here give in a tabular form, both in metres and English feet:—

	METRES	FEET	INCHES
Entire Height	49.483	162	4
Breadth	44.820	147	
Depth or Lateral Breadth . .	22.280	73	
Height of Large Arch . .	29.420	96	6
Width of ditto	14.620	47	10
Height of Small or Lateral Arches	18.630	6	1
Width of ditto.	8.440	27	7

According to a return of the Minister of the Interior, made up to December, 1836, the total disbursements from 1806 to 1836 were 10,691,098 francs 91 cent. From this sum deductions must be made for alterations, caused by political changes 876,245 francs 83 cent. and for the temporary canvass erection on the marriage of the Emperor 511,345 francs 29 cent. or 1,387,591 francs 12 cent. Thus the arch property cost 9,303,507 francs 79 cent. (372,140*l.*); of which four millions were spent under the Emperor, three millions under the Restoration, and under Louis Phillippe, three millions. The gas-fittings cost 38,464 francs 50 cent. or 1538*l.*

The best way of estimating the effect of such extraordinary dimensions, is to refer to some well-known object that will furnish a direct comparison in regard to size, and we find such comparison ready made to our purpose, in the second volume of the "Illustrations of the Public Buildings of London," (p.216,) where, speaking of Temple-bar, the Editor remarks that the whole of it, "with another building of the same dimensions above it might be comprised within the opening of the large arch of the Barriére de l'Etoile!" Looking therefore at Temple-bar, we may, without difficulty, form an adequate conception of the vast scale of the French monument, particularly when we take into consideration its dimensions in regard to depth, which are such, that the void of the great arch would contain *eight* Temple-bars, that is, four placed one behind the other, and as many above them. How prodigious then must be the entire mass! Here again we may have recourse to comparison, and when we state that the height of this mass of architecture is only about twenty feet lower than that of the spire of St. Martin's church (measured from the street pavement), and that the clock of the latter would just be on a line with the architrave of the Arc de l'Etoile, something like a feeling of astonishment will be excited.

It would be interesting to delineate this monument, and some of our own edifices drawn to the same scale; and were we to do so with regard to the Strand front of Somerset-house, we should find that even in width, it is less than the edifice at Paris, and that, though composed of an order on a lofty basement, its cornice is not quite so high as the groups of sculpture placed on each side of the arch. Consequently, in this case, we should have to imagine more than another mass equal to the Strand building of Somerset-place, reared above the one we now behold. If we take the Banqueting-house, Whitehall, one of the loftiest of our buildings, exclusive of such structures as steeples and spires, we find that it is not higher than the impost of the arch, which being the case, it is easy to judge how diminutive even the Railway terminus in Euston-square would appear by the side of this colossal pile, the top of its pediment being about six feet lower than the Banqueting-house. It is true we have several façades (among others, that of the Post-office), which, in mere length, greatly surpasses the structure we are speaking of; but they are altogether different in character—display nothing of the same mass, or of the same scale of magnitude, being produced merely by *continuation*, without any amplification of the parts themselves. Here every thing is on the most gigantic scale, the very bas-reliefs in the panels being equal to one entire side of a large room; while each of the four piers formed by the two smaller arches intersecting the large one transversely in the plan, is equal to a very lofty house, with a frontage of 50 feet one way, and 25 the other.

RALPH REDIVIVUS.—No. XVI.

THE PIMLICO LITERARY INSTITUTION, EBURY STREET.

In making choice of this building, for my present article, it is not so much with the intention of confining myself to it for my subject, as with that of taking it as a theme upon which I may enlarge with respect to one peculiarity in it. Very probably some of my readers may have never heard of it before, and will therefore wonder not a little that I should condescend to waste any words upon a piece of such utter obscureness; and among them there may be those who will give me credit for being wicked enough to drag it forth into notice, for no other purpose than that of unsparingly ridiculing some poor abortive attempt at design which every body else would consider to be beneath criticism.

It must be confessed, the building itself has nothing at all in it to arrest the attention of persons in general, more than any thing else of the same kind and size; nor is it at all improbable that many have passed it without even so much as noticing the peculiarity for the sake of which it is that I am chiefly induced to speak of it. In the general elevation there is little remarkable, it being little more than a pleasing composition in the Grecian Doric style;—a distyle in antis, with a lower and narrower lateral porti.n or wing on each side of the loggia. Although, as far as decoration is concerned, these last-mentioned parts contribute little or nothing to the design, they have considerable value in it, both by giving character to it, and by producing an agreeable contrast of solid and void, and light and shade. It is to the back-ground behind the external elevation,—to the inner part of the loggia we must look for that which confers novelty on this small façade, and distinguishes it from every thing else of its kind; namely, the screen or low wall carried up little higher than the doorway placed in it; besides which the light is partially admitted at the sides or ends of the loggia between small square pillars, placed on he level of the top of the screen. Few and simple as they are, these circumstances impart to the whole a newness, a playfulness and picturesqueness of appearance that may be pronounced almost fascinating, when compared with the unvaried sameness that pervades all our imitations of Grecian architecture, and allows of no other diversity than what arises from the order employed, and its accompanying details. It is true, the façade porticos of the Greeks themselves exhibited so very little variety that they may be described as all of them conforming to one common established model, without other distinctions than those attending the columns and entablature, and the greater and lesser number of the former. Yet this constant repetition of one and the same idea merely a little differently modified, was not, I conceive, so much a merit as a defect in Grecian architecture; nor is it any satisfactory argument to the contrary to say, that, considered individually, each example was excellent. We may have too much, even of a good thing: *toujours perdrix* is a most unpalateable dish.

It is owing to this monotony that now its first novelty is worn away, the Grecian style has of late begun to be abandoned for others. Instead of endeavouring to infuse greater variety and freedom into it, our architects have practically abridged its tether still more, and reduced its orders to mere stereotype fac-similies of certain examples; whereas, although adhering almost without exception to one uniform plan, even the Greeks allowed themselves some little liberty in regard to matters of detail: nay, so far are we from aiming at any fresh combinations resulting from plan, that I cannot call to recollection any one portico, where inner columns have been placed behind those in front, for which at least there is sufficient precedent in Grecian buildings to satisfy the most timid and scrupulous. So far then we may be said rather sedulously to shun what is almost the only source of variety, or if not the only, the chief one in Grecian architecture; reducing every design for a portico to a mere line of columns before a wall, with no other difference than what is occasioned by there being windows or not, or by there being either a single door, or a principal and lesser ones. All that is done beyond this consists in occasionally making the portico recede within the building, as well as project from it; of which we have instances in those of the Post-office and the London University. At that point we stop.

One solitary example, however, of a single step further being taken, does now occur to me, and it is that furnished by the interior of the portico of the National Gallery, where there are two columns within the break or recess containing the central doorway; yet, although as far as it goes, this circumstance alone produces considerable richness, it hardly shows itself from without, until we begin to ascend the steps; because, owing to the portico being so elevated, it is almost concealed from the spectator when he is close to it, while seen at a distance all between the outer columns is veiled in obscurity.

With no more than these two instances before us, viz., the National Gallery and the Pimlico Institution, it is easy to perceive what various modifications and combinations might be obtained; the variety attending the former being that given to the horizontal lines or ground-plan, while in the other case, it lies in the section or vertical plan, both which species of variety might be resorted to, wherever a more piquant effect than would be attainable by employing only one of them was aimed at.

In order to render this more intelligible by something like direct exemplification of the principle recommended,—and unless I do so people will hardly be at the pains of giving it any serious consideration—I will here briefly point out one or two of the numerous combinations that may be obtained as soon as we break through the dull and wearisome fashion of placing one uniform plain wall behind columns, whose blankness is interrupted merely by the entrance or entrances. After admitting the screen in its simplest form—in which it presents itself at the Pimlico Institution; the next step would be to bestow some decoration on it, and to place either a statue or large bust in the centre over the doorway. It still remains, however, a simple screen, dividing the lower part of the portico into an inner and an outer one. We must not stop here, or if we do we shall lose not only that variety which serves to distinguish one design for another, but also those contrasts and complex effects which may be brought into a single design. It will be desirable therefore to admit square columns behind those in front, between the lower part of whose shafts the screen would be inserted; another mode would be to employ columns, placing them either immediately before or behind the screen, and occasionally to combine both modes, letting columns be seen beyond it, as well as in front of it; other variations present themselves in regard to the screen itself, since it does not follow that it must needs be of uniform height throughout—for whether it be divided into inter-columns or not, it may rise up in the centre where the entrance is placed, so that its fascia shall there coincide with the cornice of the doorway. Neither is there occasion that such screen should invariably be carried the width of the inner elevation of the portico: on the contrary, it might sometimes be confined to the centre, or vice versa; the doorway, in the latter case, being placed in a wall carried up to the soffit of the general architrave. Light, again, might occasionally be thrown upon the part seen beyond the screen, either from the side or from above; which would certainly greatly enhance the effect, and produce that kind of display of which we have as yet no instance whatever; and if I may be allowed the liberty of pointing out a portico where something of this kind could have been introduced without going at all out of the way in order to obtain it, I would refer to the portico of the Post-office, where had the compartment in which the great door is placed been separated from the hall merely by a screen carried up as high as the consoles against the jambs of that doorway,—which would have been even more economical than the present wall,—the upper part of the hall and its columns would have been seen over it in such manner as to produce a striking architectural scene. In fact, so much novelty, so many combinations, might be thus produced, that although not at all difficult, it would be tiresome to point them out more particularly.

That any one will be induced by what I have said to take these suggestions into deliberate consideration, is what I do not expect: well am I aware that I might all this while just as well have been "whistling jigs to the moon." Most people turn up their noses at "advice gratis,"—architects among the rest: therefore they must go on to the end of the chapter, with their single row of copied columns in front, which constitute their classical porticos. All I have to remark is, that the sooner they come to the end of that very dull chapter, the better.

CANDIDUS'S NOTE-BOOK. FASCICULUS IV.

> I must have liberty
> Withal, as large a charter as the winds,
> To blow on whom I please.

I. Most persons seem to think that they have a right, when building, to commit whatever vagaries they please, and that it is excessively impertinent in any one to impugn their taste, be it ever so absurd. Certainly the legal right cannot be disputed: legislation, which touches every thing else in this country, where freedom consists in the liberty of making some new shackles for ourselves every day, has not as yet laid its hands upon taste. In building, a man has a most unquestionable right to please himself—if he can, whether he so pleases his neighbours or not; yet so has he a right to wear either his own nightcap or his wife's bonnet instead of a hat; and other persons have the right to laugh at him as much as they please in their turn.

II. For an experiment in polychromy on such a scale as should satisfactorily determine how far it is really valuable, how far consistent with good taste or the contrary, we have nothing so suitable as the York Column. In fact, it could not have been more so had the architect expressly intended it to be so finished up, for at present it strikes quite as much by its bareness, and the utter absence of all decoration as by any-thing else. There are several circumstances which recommend it—I might say, plainly point it out as a fitting architectural subject for such purpose: its being insulated in such manner, and its being of such form, that the effect which might be produced could not possibly violently interfere with any thing else: further, its being precisely the kind of structure to ornament which may be applied unsparingly, with the greatest propriety, or, rather, one which absolutely demands it. Yet, although I am of opinion that the experiment might be made with perfect safety as to the result, by no means would I advise that it should be a hap-hazard one: on the contrary, if it was intended that it should succeed, the utmost study should be given to it beforehand. A model, at least ten or twelve feet high, ought to be prepared,—one capable of showing the minutest details of every piece of ornament; and this should not only exhibit the precise colours, but the same pigments which are employed in polychromy. So, then, I actually propose that the poor York Column should not be whitewashed—as some have fancied Westminster Abbey ought to be—but daubed over of as many colours as a Harlequin's jacket displays, by way of introducing the outlandish architectural fashion termed polychromy? To be sure I do;—though, of course, the "daubing" and the "Harlequin's jacket," would be re-echoed from all sides against such a scheme. It is hardly worth while to discuss how far painting and daubing are one and the same operation; besides which, it might lead to some excessively *odorous* comparisons; but, as for the Harlequin's jacket, I enter my solemn protest against *that* comparison, which, were I to fling it any where I should fling at some of Turner's blue and brimstone pictures—daubings, I had almost said. No, I am of opinion that greys and warm neutral tints, with an inter mixture of light bronze-colour, sparingly relieved by touches here and there of different brilliant hues, would be most suitable; if properly managed would produce soberness without dullness, and sufficient energy and vivacity, without either crudeness or garrish glare. The positive colours ought perhaps to be applied to the grounds of the ornaments, rather than the ornaments themselves, in such manner as that these latter would appear a rich broidery of figures, foliage, and other embellishments, through whose interstices differently coloured surfaces would appear. As to the arrangement of the ornaments, they should be in horizontal zones, whether with plain spaces between them or not; but certainly not in a continuous spiral from top to bottom. My project is a very excellent and a very feasible one, and would certainly be realised to-morrow, were I but lucky enough to pick up Fortunatus' wishing-cap to-night.

III. If there be any truth at all in any of the representations I have seen of Abbotsford, it is but a sad sample of Sir Walter Scott's taste, being a most Brummagem piece of architecture and antiquarianism, hardly a whit superior to Strawberry Hill. In the print he gives of the house, Dibdin makes it a complete architectural scarecrow, such a motley and beggarly jumble of odds and ends, that its look is any thing but inspiring. It is wonderfully anti-poetical in the fancy it exhibits, so much so, that one would imagine it to have been built by some retired cheesemonger, or other vulgarian of that grade. Had such been the case, its ugliness would have been a by-word to all the world. Now, if the public insist upon deifying Sir Walter, well and good; but as for Abbotsford, we may surely be allowed to give the taste shown in it, if not the house itself, to the devil.

IV. The author of the "Original" has some very peculiar notions on the subject of dining-rooms; one or two to which I cordially assent, others from which I as cordially differ. I admire the perfect good sense with which he is satirical at the expense of those would-be-thought genteel people who make the giving a dinner an affair of fidget and fussiness, and thereby often entertain their good-natured friends very far more than they intend to do. From the very first you perceive the extraordinary state of things: all is masquerade, except the whole absurdity of the business—which stares you in the face without any disguise. But this is a subject I must turn over to Boz—who, I presume, is capable of doing it justice; and who, for aught I can tell, may have excercised his talent upon it already—for were I to allow myself to run on upon it, there would be no space for any thing else in this number of the Journal. But all this is merely a *scappata*.

Agreeing with Mr. Walker, that dining-rooms in London are in general very tasteless and uninspiring, I do not enter into his notions for rendering them otherwise; neither do I at all approve of attempting to establish rules, which however suitable they may be in some cases—or even the majority of them—may prove quite the reverse in others. The only rule that ought invariably to be adhered to is to provide a side-board alcove; for without this, instead of appearing to have been originally intended for its purpose, the room will appear to be merely made use of for dining in, for want of one better adapted to the purpose. Although preferable to none at all, a mere shallow recess for the side-board is little better than an apology for one. The recess ought to be deeper than the side-board itself, so as to have the appearance of being a space added to the room, capable of containing, besides the side-board itself, whatever it may be convenient to have at hand during the time of dinner. If this be attended to there will always be a certain degree of character and effect independently of any thing else; besides which, within a deep alcove there can be a door through which servants can go in and out with less interruption to those at table than otherwise; and if the recess be wider within than towards the room, so that such door be more or less concealed from view, all the better. But whatever others may think of it, I certainly do not at all approve of the worthy magistrate's whimsical idea of a 'quiet little kitchen' immediately adjoining the dining-room, and communicating with it by an entrance close to the side-board, closed during the process of dinner by a *curtain only!* I have no objection to his fixing the number of eight as the maximum for a comfortable dinner-party, if merely because that regulation would effectually prevent the misfortune of there being thirteen at table; neither do I quarrel with him for recommending the least possible number of attendants, it being anything but agreeable to have a regiment of flunkies crowding the room, and reconnoitring the company during the whole of their feeding-time. On the other hand, I certainly see no reason whatever for the arbitrary rule which would restrict the width of the room to what is just sufficient to allow the attendants to pass round the table without jostling against each other; in other words, the room ought, according to Mr. Walker, to be invariably a very narrow one.

This is absurd enough: and, in fact, all restrictions and positive rules in regard to colour, decoration, and other matters of a similar kind, are not only useless, but worse than useless; because were they attended to they would put every dining-room into a standard uniform, which is anything but desirable for there is at present far more monotony and sameness than one would wish to meet with. We rather want variety; and there is certainly ample scope for it. The only rule which ought to be received as applicable in all cases, without exception, is that EVERY THING OUGHT TO BE CONSISTENT THROUGHOUT, TO BE IN EXCELLENT TASTE, AND TO PRODUCE AS MUCH EFFECT AS THE ACTUAL DESIGN WILL ADMIT OF. Instead of fettering the artist, and putting his ideas on a Procrustean bed, this rule leaves him at perfect liberty. So far from being required to be invariably sober, modest, chaste, or whatever else of the kind we style it, a dining-room may be as splendid as any other apartment in a house; with this difference, that its splendour must differ in kind from that of the drawing-room and boudoirs. In fact, sumptuousness, rather than the contrary, ought, in many cases, to be the prevailing character, especially where there is a prodigal display of plate. Nor by sumptuousness do I mean gaudiness: *tout au contraire*, the former may be made to exclude the latter. Let there be, for instance, in order to give something like a positive and tangible example, a deep alcove—semicircular perhaps in plan—lined with draperies of purple velvet, to relieve the gold and silver plate on the side-board. Give this alcove a double screen of white marble or scagliola columns in front, between which would be placed lofty candelabra. The walls might be incrusted with scagliola of a darker tint than the shafts of the columns. The window draperies would of course match those of the alcove, at least in material, supposing a different colour to be selected for them;—ceiling of an architectural design, either simply white and gold, or relieved by colours in its lacunaria;—for ornamental furniture against the walls, we would have marble pedestals alternately supporting lesser candelabra, and gilt or alabaster vases filled with a profusion of flowers—but mind, artificial ones. Now I conceive that if properly arranged, so as to avoid all appearance of crowding together more than the space would allow, the kind of effect might be produced which would not at all be out of character for a dining-room, namely, the *Festal*. As for Mr. Walker's nice quiet little kitchen, I will take the liberty of shoving that under the dining-table.

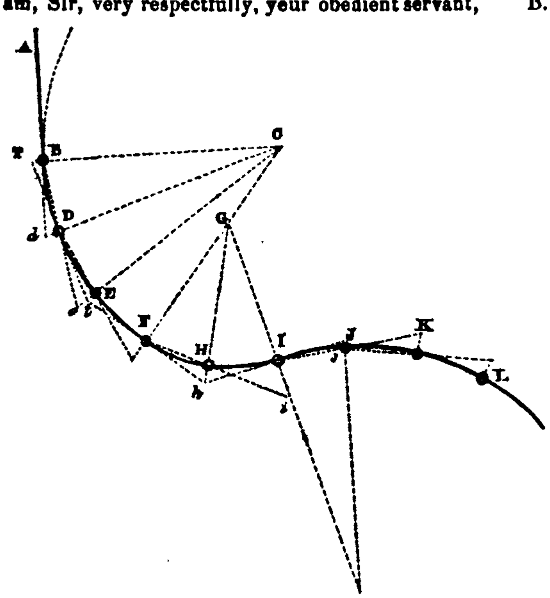
RAILWAY CURVES.

SIR,—Like your correspondents in the journals for January and March, I have been employed in making out Railway Curves; but in a country extremely unfavourable to the formation of railways, both as respects gradients and curves, and where, consequently, inclinations of one in 200 or 300, and curves of one quarter mile radii, are looked on as favourable. On sharp curves, you must be aware, it is necessary to elevate the outer or longer side, one, two, three, or even more inches, above the other, in order to assist the carriages in travelling round them. In short, without such a practice, curves of short radius would be impassable. But as the one rail must be raised above the level of the other gradually, and as gradually descend to the level of the same, the difference of level must be the greatest in the centre of the curve, and therefore the tendency of the carriages to fly off the rails, will, so far as it is affected by these means, be *least* towards the *centre of the curve*; or, in other words, *to make that tendency uniform throughout, the curve must be made sharpest at its centre*, and therefore leave the straight line at a larger radius than it afterwards assumes; as recommended by your first correspondent: but, as in curves of a mile or two radius, this reason does not obtain, I must agree with your subsequent correspondent on the subject, that, in general, the practice under discussion would be not only useless but injurious.

By the raising the outer rail of a curve above the inner, I know of a railway curve (of the ordinary 4 feet 8½ inch gauge) of only 5 chains radius, which is readily passable by locomotive and train; and a curve of about 1 ¾ chains radius on the same railway round which (though certainly with considerable difficulty) heavy waggons are daily pulled by horses.

I know nothing of the modes *usually adopted* on laying out railway curves, therefore, for what I know, what follows may be unworthy of notice on account of novelty; but, for the sake of your junior readers, may possibly be worthy of insertion in your widely extending journal.

I am, Sir, very respectfully, your obedient servant, B. W. T.



1.—To mark out a curve of a certain given radius.

Let AB be the straight line of a railway, B the point where the curve is intended to commence. BC, DC, &c. radii of the curve to be described, D d the deviation from the straight line at the end of any convenient length B d, then $\overline{C d}^2$ or $(CD + Dd)^2 = CB^2 + Bd^2$ or $CD + Dd = \sqrt{CB^2 + Bd^2}$ *i.e.* $Dd = \sqrt{CB^2 + Bd^2} - CB$, produce BD to e, making $De = Bd$, and draw TDt a tangent to the curve at the point D, then the triangle TDB will be = and similar to the triangle DBd, and the angle TDB is = the angle eDt being vertical; also $TD = tD$ and CB, CD, &c., being very great in comparison with BD, DE, &c., the triangles DtE, Det may be considered practically equal and similar, and therefore $Et = te = Dd$ or $Ee = 2Dd$, which may be found by the above formula, where CB is the radius of the proposed curve, and Bd, any convenient length between the several points B, D, E, &c., is to be found.

The rule in words at length may be expressed as follows:—Add together the square of the radius and the square of the distance apart of the points to be found in the proposed curve; take the square root of their sum, and take from it their radius: the result will be the amount of deviation from the straight line in the given length—which will give the first point of the curve; after which the deviations must be doubled, to render the curve uniform.

2—To change from a greater to a smaller radius, or vice versa.

Suppose at the point F the curve changes its radius, having now the shorter radius FG, it is evident the curves BDEF and FHI, should have a common tangent at F, which tangent may be found (on the ground) by taking $Et = \frac{1}{2} Ee$, and tF will be the common tangent, then the direction of the tangent tFh being found, the amount of deviation (hH) for the length Fh and radius GH may be found as before; then by producing FH to i, and making the deviation Ii double Hh, another point I of the curve is found. In practice Ii &c. may be measured at right angles to FHi, &c., the figures of course, being very much distorted; thereby rendering the angle HiI, which in practice might be taken as a right angle.

3.—To describe an S curve.

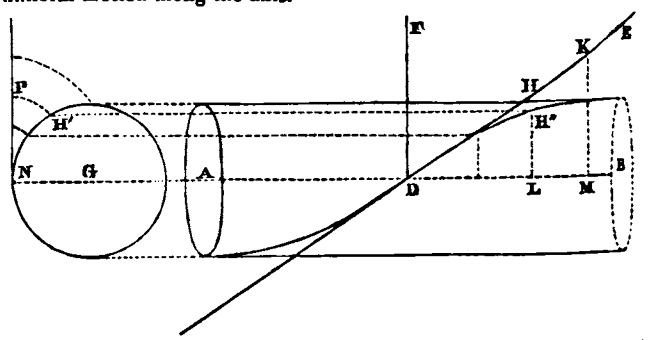
Suppose I to be the point at which the curve changes; then the curves FHI and IJK must have a common tangent at I, which can be found as before; also the deviation Jj, which being doubled, any number of points, as K, L, may be found.

SKEW ARCHES.

SIR—The usual method of obtaining the spiral courses, in drawings of skew arches, is productive of much labour.

I have been led to believe that the following plan is much simpler, more expeditious, and consequently easier of comprehension; and although the same idea may possibly have occurred to others, it may not be so generally known as to be entirely unacceptable.

A spiral is defined as being a line traced upon the surface of a cylinder, by the extremity of a revolving radius, which radius has also a uniform motion along the axis.



Let AB, fig 1, be a cylinder, and DE any line making an acute angle with the axis, it is evident that the line DE, is the locus of a point having a uniform motion, in each of the directions DB, DF, and if the line DE be wrapped round the cylinder, it will still possess the same property, only that the motion in the direction DF, will be transformed to a motion round the cylinder, and the line will thus become a spiral.

I have said this in order to show, as clearly as possible, that a straight line, when wrapped round a cylinder, produces a curve conforming to the definition of a true spiral, and will now proceed to explain the simplest method I have found of projecting this curve.

If a piece of paper, having a straight edge, represented by the line DE, be rolled round a cylinder, it will be found that all the points H, K, &c. will approach the cylinder, in vertical planes perpendicular to the axis, the edges of which planes are represented by the lines LH, MK.

Hence it will be seen, that to ascertain the position of any point H, when the line DE is wrapped round the cylinder, we have only to wrap round the line LH; this may easily be done by drawing an end view G, of the cylinder, and taking NP equal to LH, finding NH' the length of the curve equal to NP,* and projecting the point H' to H'', we obtain the position that H will occupy upon the cylinder. In the same manner all the points in the curve may be found.

We now come to the practical application.

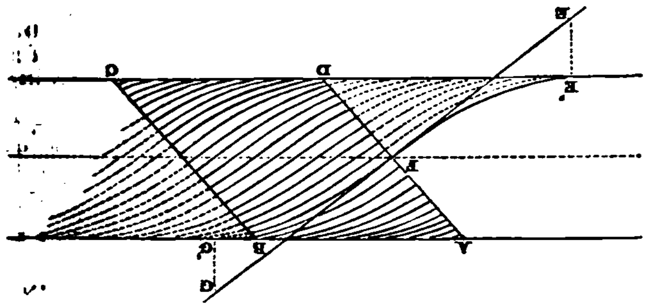


Fig. 2.—Let ABCD denote the outlines of the plan of the soffit of a skew arch, and let EFG be drawn making the proper angle† with the face.

Then by the plan I have just described, the line EG may be wrapped round the cylinder, and E' FG' the curve generated, will represent one of the spiral courses. Now each of the courses of a skew arch would, if produced, wrap itself round the cylinder, and present a curve similar to E' FG', hence every one of the courses of the arch will be a portion of this curve; if, then, a mould be cut to the curve E' FG', it is evident that by setting on the proper distances, along the lines AG' E'C, and applying the mould to the corresponding points, all the courses may be drawn, as shown on the figure, with little trouble.

I believe the common practice is to project each of these joints on the soffit separately; where the arch is brick, and each course shown, this is a work of much labour.

The same principle, with a little modification, is applicable to the other views of the arch, more particularly to the outline of the developement of the soffit, only that in this case the operation is unrolling instead of rolling the line.

In case any may not understand the preceding explanations, I would recommend those who feel interested in the matter to try the experiments with the paper and wooden roller, and they will quickly perceive the principle.

B. & G. Railway-office, Worcester. Your's obediently, H. Spencer.

PLYMOUTH BREAKWATER.

A communication from Sir John Rennie *to* T. L. Donaldson, *Esq.*, Hon. Sec., *read before the Institute of British Architects*, April 11th, 1839.

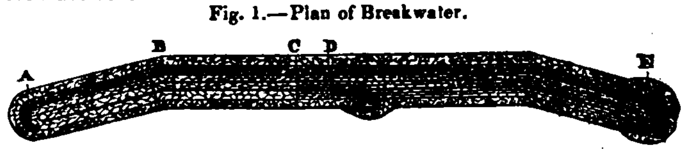
Dear Sir,—I have the greatest pleasure in complying with your request, relative to the construction of the Breakwater in Plymouth Sound, and I shall always be extremely happy to forward the views of the the Royal Institute of British Architects in any way which may be considered most conducive to the welfare of that valuable society, in which you take such a laudable interest, and only regret that your application of yesterday had not been communicated to me earlier, in order that I might have been enabled to render the following account more complete, and more worthy of the society; and as I have written this chiefly from memory as far as the shortness of the time would allow, I trust that every allowance will be made for any omission, as I am about publishing a work upon Harbours, in which the subject will be more fully explained hereafter: and I entirely agree with you, that although strictly speaking, a work like the Breakwater may not generally come within the range of civil architecture as now practised; nevertheless it is to be hoped that the study of it may be found not altogether unprofitable; the more so, as Vitruvius, the earliest founder of the art, includes a knowledge of these kind of works among the necessary acquirements of the architects. I shall now, therefore, proceed to the description of the work in question.

* This may be done by calculation, but measurement by compasses is near enough for practical purposes.

† This line would be at right angles to the face, on the surface halfway between the soffit and crown. (See Mr. Fox's Pamphlet on Skew Arches.)

Plymouth Sound, from its extent, its depth of water, the numerous creeks and rivers which discharge themselves into its bosom, and its proximity to the Atlantic Ocean, had long pointed itself out as one of the principal stations for the British navy; and at an early period of our history, Devonport was selected as the chief port for fitting out vessels of war for the western portion of the kingdom; and although on account of the exposed nature of Plymouth Sound, a certain degree of inconvenience was more or less experienced during the infancy of the British navy, nevertheless, it never became so apparent until the tremendous conflict of the last war, when it became absolutely necessary for self defence to increase our fleet to that extent, that more than ordinary accommodation became necessary; it was then that the danger and inconvenience of the Sound became most apparent, and imperiously called for a remedy; various ideas had been suggested, and numerous plans proposed to obviate the existing evils, until at last the Admiralty applied to the late Mr. Rennie, my father, who proposed to erect a detached or isolated breakwater in the centre of the Sound, which, after a great deal of discussion and opposition, was finally approved of, adopted, and ordered to be carried into effect; and the first stone was accordingly deposited in the summer of 1812. The reasons for adopting the isolated or detached Breakwater were; first, because this part of the Sound was already obstructed, and to a considerable extent rendered unnavigable by the Panther, Shovel, and Tucker rocks: secondly, by placing it in the centre of the Sound, there would be an entrance at each end available for vessels to take advantage of either an easterly or westerly wind, which would considerably facilitate their entrance or departure to or from port: thirdly, by having two entrances there would be a greater facility for the reception, and discharge of the tidal and fresh waters, and thus maintain a more general and equal circulation of the current throughout the estuary and its various receptacles, and prevent the deposit and accumulation of sedimentary matter, with which the waters are more or less charged; and thus, whilst protection against storms would be gained, the depth would still be maintained, which constitutes one, if not the most difficult problem in the construction of harbours. The correctness of Mr. Rennie's decision has been fully corroborated by the result, for, contrary to general anticipation, the depth of the Sound has not been found to decrease, but rather to augment; as otherwise, although the embankment of several marshes over which the tide used formerly to flow, and thus to contribute and augment the scour or backwater, might reasonably have been supposed to have produced a different result, and should if possible have been avoided.

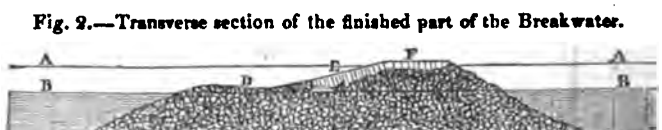
Fig. 1.—Plan of Breakwater.



Scale of yards, each divison 100 yards.

The span between A B, or eastern arm, is about 10 feet above low water spring-tide: B to C is finished with rubble;—C to D is to be finished with masonry;—D to E is finished with masonry.

Fig. 2.—Transverse section of the finished part of the Breakwater.



Scale of feet, each division 10 feet.

A A, High water spring-tides;—BB, Low water spring-tides;—CC, Original bottom, varying from 40 to 45 feet below low water mark;—D, The Foreshore;—E, Sea slope;—F, Top 45 feet wide.

The first stone was deposited August 12, 1812,

Quantity of stone deposited to April 3. 1830	.	2.603.979 Tons.
Ditto from do. to January 22. 1833	. .	611,423 ,,
Ditto from do. to March 31, 1838	.	68,311 ,,
Total	.	3,283,713

By referring to the plan, it will be seen that the Breakwater is composed of three arms, the centre being 1,000 yards, and the two outer arms 350 yards each, and inclines at an angle of 20 degrees to the main arm, and comprehending a total length of 1,700 yards at top, or 1,770 yards, or one mile, at the low water line. The exterior slope or inclination taken below the line of low water has been left for the sea to form, and is found to be at from three to four feet horizontal to one foot perpendicular, and in parts rather steeper, but from low water upwards, which has been set artifically, it is five horizontal to one perpendicular. The inner slope or that next to the land is nearly two feet horizontal to one foot perpendicular from the base to the top, which is two feet above high water of spring tides, and forty-five feet wide, rising one foot additional towards the centre. In addition to the sea slope above described, by referring to the drawings, it will be seen that there is an exterior berne or foreshore thirty feet wide, at the extremity of the east end, fifty feet wide in the centre, and seventy feet wide at the extreme west end. This foreshore, it will be seen, rises from the toe or base of the outer slope to about five feet above low water at its outer extremity, and serves to break the waves before arriving at the main body of the work, and thus diminish their force, and at the same time to prevent the recoil or back stroke of the wave from undermining the toe or base of the slope, and thus making a breach in the body of the work, which at times might otherwise occur to a certain extent. Towards the centre of the inner slope or face of the Breakwater (see fig. 1.), it will be seen, that there is a small jetty with a double returned head, for the purpose of enabling boats to land under protection. At the western extremity it will be seen that there is a circular head 570 feet diameter, upon which there is to be constructed hereafter a lighthouse, so designed as to throw a complete light over the entrance, at the same time to point out the anchorage, so that vessels entering at night may come to their moorings with the greatest facility, without fear of running foul of any ships which may already be there. The general depth where the Breakwater is placed varies from thirty-six to sixty feet at low water of spring tides, which generally rise about eighteen feet, and neaps twelve to fourteen feet. The eastern entrance is half-a-mile wide, and varies from six to seven fathoms at low water, and the western, which is the principal entrance, is about half-a-mile wide, and varies from seven to nine fathoms deep at low water spring tides, and the anchorage, where there is fine holding-ground, varies from eight to nine fathoms at low water spring tides.

The heaviest and most frequent gales come from the southward and westward, and the wind prevails chiefly from the latter quarter about nine months out of the twelve; and during gales from this quarter, which are very severe, exposed as it is to the uninterrupted reach of the Atlantic and Bay of Biscay, with such a range of sea and such a depth of water, it may readily be conceived that the sea must necessarily be very heavy, and require a corresponding degree of strength to counteract its disasterous effects.

The great mass or body of the work is composed of limestone brought from the quarries of Overton, lying at the mouth of the river Lary, called Catwater, about four miles distant. The stone is raised in various sized blocks, from one quarter to ten tons and upwards in weight, which are thrown promiscuously into the sea as they are raised from the quarry, in the line of the Breakwater, taking care that the greatest proportion of the large blocks are thrown upon the outer or sea slope, and that the whole, large and small, are so mixed together, that the mass may be rendered as solid as possible. In addition to the smallar class of rubble abovementioned, quarry rubbish and lime screenings are thrown down from time to time in order to fill up the smaller cavities. You must observe, that during the progress of a work of this nature, to a certain extent, storms are extremely beneficial, for they serve to wedge and consolidate the whole mass together, much more effectually and in much shorter time than human art could perform; and indeed it is desirable not to hurry until the work, as it proceeds, has been consolidated by the sea in the manner above described,—for until this has been effected and sufficient time allowed, it is in vain to attempt, successfully, the erection of any superstructure. As I have already observed, the work commenced in 1812, and continued with considerable activity until 1824, during which period scarcely any storms of consequence occurred, and the great mass of the work had been completed below low-water mark, and about half of the superstructure from the eastern end towards the centre had been carried to the full height above high water, and, judging from what had passed, the able and excellent superintendent, the late Mr. Wheatley, one of the most experienced officers in the navy, concluded, that it was necessary to incur the expense of an outer slope of 5 to 1 as originally proposed, and considered necessary by the late Mr. Rennie. The great storm, however, of Nov., 1824, completely established the accuracy of Mr. Rennie's calculations, for the sea increased the outer slope from 3 a 5 to 1, and transferred with the greatest nicety the superfluous rubble from the outer to the inner slope; the area of the one was nearly equal to the area of the other, making the requisite allowance that the former had become more consolidated by time than the latter. In proportion as the work advanced, it was found that the sea became much more heavy towards the western end, and consequently rendered a more solid description of work necessary; I therefore recommended that the surface should be cased with masonry and a foreshore on the sea-side, encreasing in substance and strength as it approached the west end, where the whole from low water to the top is composed of solid masonry, dowelled, joggled, dovetailed and cramped together, and the foreshore to be regularly set as far as practicable, and using the diving-bell to found the lower courses below low water. I also recommended that air or vent-holes should be made on the surface of the casing where requisite, to enable the air compressed by the waves to escape and prevent it from blowing up the covering; although it was found by Mr. Stewart, the present intelligent and experienced resident superintendent, that where sufficient time had been given for the rubble below to become consolidated by the sea, and the masonry casing had been carried up solid from low water, that the vent-holes were unnecessary. By referring to the drawings, you will observe that the stones coloured grey represent granite, which being obtained in larger blocks than the limestone, being more tough and not so brittle, has been found to resist the shake of the waves much more effectually. The lower, or footing granite courses, upon which the rest of the superficial casing abuts, are laid horizontally on their beds, the better to resist any lateral thrust which might otherwise result from sliding; the same may be observed of the middle, or bonding course, which is also of granite. The whole of the three granite courses are dove-tailed together, as well as being lewised and bolted to each other, so that they may resist effectually every shock to which they are peculiarly liable.

The mortar for the masonry is composed of one part Italian pozzolano, one part aberthaw, or Plymouth lime, mixed up with two parts of fine sharp clean fresh water sand, the whole being thoroughly mixed together, triturated under a mortar mill, and worked up with as little water as possible; this mortar very soon sets, and in a short time becomes as hard as stone. The exterior beds and joints for a few inches inwards are pointed with the best Roman cement, which has the property of setting directly, which is encreased by using warm water, but then it has the disadvantage of being easily broken and not uniting again, the other being decidedly preferable as soon as it has set. I also recommended that a mass of concrete, composed of similar materials as the mortar above described, only using five parts of sand, more or less, according to the position, should be used in the interior of the work to bed the blocks upon, near the level of low water; this kind of concrete I have been in the habit of using for many years past in various maritime works with great success, and even below low water, where, if protected and used in masses together so as to prevent the waves from acting upon it until some time after it has been deposited, soon becomes very solid and durable.

The loose rubble blocks are transported and deposited in their position in the following manner:—after having been worked in the quarries they are transported by railways to the quay side, they are put on board of vessels built expressly for the purpose. These vessels are about sixty tons burthen and upwards, and have two railways laid parallel to each, which traverse the hold of the vessel from stem to stern, which can be made to open entirely—as the railways approach the stern-port they form an inclined plane, the last part of which is made to revolve upon an axle, with a check to prevent the truck from going overboard with the stone; on the deck of the vessel there are fixed powerful crabs or windlasses. The blocks of stone, together with the trucks, are put on board the vessel, ranged in parallel rows on the railways before described. The vessel then takes her departure for her station at the Breakwater, the whole of which has been previously marked out with a sufficient number of buoys; and upon her arrival at the particular spot where stone is required, she is immediately moored to one of the buoys in question. The crew then commence their labours of discharge by heaving up the trucks containing the blocks of stone, by means of the windlasses on deck; and when the truck arrives at the termination of the inclined plane at the stern of the vessel, its own weight tilts it over, the block of stone is discharged into the sea in its proper place, and the truck remains; it is then placed upon the deck of the vessel, and there left; and in like manner each block is successively discharged, until the whole cargo has been disposed of: this operation, which is extremely simple, is very soon completed, seldom occupying above a quarter of an hour or twenty minutes; the vessel then returns to the quarry for another cargo, and, according to the state of the wind and weather, will make several voyages a day. At times steam-tugs are used to take them to their stations, which saves a good deal of time; but as the wind blows from the westward during a greater portion of the year, they generally sail back to the quarries. In order to ascertain the state of the work below low-water, frequent sections are taken on the line of the buoys before-mentioned at about every ten yards, and a regular register and journal is kept of the whole proceeding, so that the actual state of the work at any one period can be ascertained with accuracy.

The work has now been in operation nearly twenty-six years, but the great bulk or mass of the work, which renders the Sound a well protected roadstead, was completed ten or twelve years ago. The operations are now chiefly confined to the west end, where they are employed upon making the solid masonry foundation for the lighthouse, which is a work requiring a good deal of nicety and time to complete, particularly the foundation courses, which are to be laid by the diving-bell: but on account of the swell which so frequently prevails there, many days elapse when it cannot be used, so that the Breakwater, with the exception of this part, may be said to be almost completed. The original estimate of the late Mr. Rennie for the rubble alone, without the masonry, casing, or lighthouse, was, I think, 1,150,000*l.*, and these two latter works have been estimated at from 250 to 300,000*l.* more, so that the whole will not exceed 1,500,000*l.*; which I trust will be allowed as coming very near to the original calculations, considering the difficulty of works of this nature, exposed as they necessarily are to the vicissitudes of the elements, which render them peculiarly liable to casualties.

For the above short account, I trust that I have fully complied with your wishes as far as the short period of notice you have given would allow. I believe that I have not omitted any very material point, although you are fully aware that there is a great deal of detail which could not be included in such a necessarily confined account—it is of less importance now, as it will be included in my work previously referred to. The accompanying drawings, from which the work has been executed with some slight modifications according to circumstances combined with the above descriptions, will, I think, render the whole subject sufficiently intelligible.

Believe me very sincerely,

London, April 6, 1839. JOHN RENNIE.

A TREATISE ON RESERVOIR LOCKS.

BY J. A. ROEBLING, CIVIL ENGINEER.

(*From the American Railroad Journal.*)

By the term reservoir locks, is understood locks connected with reservoirs which receive and reserve a certain portion of the lockage water for the purpose of floating a vessel from one level to another, and which reserved portion of water is let into the lock-chamber again when another boat is passing the lock. As the reservoirs are alternately drawing and discharging a certain portion of the water, it is obvious that they may be so located as to use a far less quantity of water for passing vessels through the lock than is commonly wanted.

These preceding remarks will be sufficient to attract the attention of engineers, and lead to the suggestion that this kind of lock is of the greatest importance in a country where the summer season is generally dry, and where the want of a sufficient supply of water for lockage often interferes with navigation; further, that by means of these locks expense will be saved, and that a canal may be constructed, and kept navigable, where in the other case sufficient water could not be furnished for supplying common locks of ordinary lifts. An eminent engineer in England, where this subject is at present treated with much interest, lately claimed to be the inventor of these locks, but without any right. As far as the writer of this is informed, but one lock of the kind in question has ever been constructed until this day. This lock was built in France, under the reign of King Louis XIV., by an eminent engineer at that time. M. Belidor, in his "Architectura Hydraulica," gives a brief account, and a cross-section of that lock, which has about twenty feet lift, and stands at the point of junction of two canals. The level of one canal lies twenty feet above the level of the other, and the lower canal is supplied with the necessary water by the upper one. The ground at the junction, in the direction of the lower canal, drops down at once, and offered a favourable opportunity for the construction of a high lift-lock, with reservoirs. The head of that lock is constructed in two offsets, with two upper gates to divide the pressure of the water against the gates. This lock answers the purpose in every respect, and draws not quite seven feet water from the upper level, for passing a boat through the chamber. About three minutes of time more are required, when the two reservoirs are used, than when not, for the passing of a boat, and there is no more stamping of the boats during the passage than in a lock of seven feet lift, as the head of the water-pressure is never above seven feet.

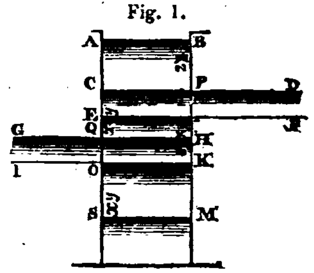
The first locks of this kind, in this country, are now being constructed on the Sandy and Beaver Canal, under the direction of Mr. E. H. Gill, Chief Engineer on that line, who by this improvement will considerably add to the already well established credit which that work greatly deserves, for the superior construction of its splendid locks and dams, and, in fact, for the solidity of all the works. Mr. E. H. Gill occasioned the writer to examine into the nature of this object to establish its theory, and demonstrate formulæ for computing the best dimensions of the reservoirs, the location of the communicating culverts and valves, and the water saved. He afterwards experimented with a model, to see how the theory agreed with the reality, and satisfied himself in every respect as to the practicability and the utility of reservoirs.

As the saving of water depends on the number of reservoirs attached to a lock, their areal extension, and on the placing of the culverts and valves, this matter must be rightly understood, and all dimensions must be fairly calculated, which calculations, however, are very easily performed. I offer here a general demonstration of the theory of this object, which for its plainness will easily be understood.

The number of reservoirs attached to one lock, may be one, two, three, four, and even more; a greater number than four seldom will be required, and found applicable: in most cases two reservoirs will answer the purpose. But there may be locations found where the ground offers sufficient room, and suits well for the construction of four reservoirs, two on each side of the lock, and where by these means a very great saving of water will be obtained.

The annexed drawing, fig. 4, shows the cross-section of a lock of fourteen feet lift, with a reservoir of 5,400 superficial square feet, on each side. The diagrams 1, 2, and 3, are likewise to represent cross-sections of the lock-chamber and reservoirs on each side. By the linear shadings are represented the different stages which the water will alternately occupy in the chamber, and in the reservoirs. The lines A B and S M represent the upper level, and the lower level, in all the diagrams; and by the lift of the lock, is to be understood the elevation of the upper level A B above the lower level S M. These two levels are supposed to be always permanent, and not to be altered.

Fig. 1.



To make the case more simple, it is supposed that each reservoir is to be as long as the lock-chamber is in the clear, and twice as wide, so that the area of each reservoir be equal to twice the area of the chamber. Let the required height which the water will occupy in the upper reservoir, be denoted by the letter x; the height of water in the lower reservoir, be denoted by y.

By examining the first diagram, any one will admit the following suppositions:—

1. When the valve of the upper reservoir is opened a quantity of water A B C P of the chamber will enter the reservoir and will flow in. till the water surface in the chamber and reservoir, C P and P D, form one level. Now, suppose this reservoir shut, and the valve of the lower reservoir opened, the quantity of water marked by C P Q H will escape and enter the lower reservoir, till the water surface is sunk to an equal level G Q H. After the lower reservoir is shut, there remains a quantity of water in the chamber, marked by the letters Q H S M, which lies above the lower level, and of course must be drawn off into the lower canal, in order to clear out the boat.

2. Now, take the case reversed; when a boat is to pass from the lower level to the upper level. After the boat has entered the chamber and the lower gates are shut, open the paddle of the lower reservoir, and draw the reserved water into the chamber. All dimensions being right, this quantity of water should exactly fill out the space S M O K, so that the top water line, O K, and the bottom of the reservoir, I O, be in one level, and no water remains in the reservoir above that level. The boat will now be raised to the level of O K. After the lower reservoir has discharged itself, shut it, and open the paddle of the upper reservoir, and draw off its reserved content of water. This quantity of water should exactly occupy that space in the lock chamber marked by E N O K, so that no water remains in the reservoir above the level of N F, representing the bottom of the upper reservoir. To raise the boat to the level of the upper canal, a quantity of water A B E N is yet required, which must be drawn from the upper level into the chamber, after the valve of the upper reservoir is shut up.

In the first case, that quantity of water which has actually been drawn from the upper level, is marked by the lines S M O K, the quantity of water saved is marked by A B Q H.

N

In the second case, the quantity of water actually spent, is marked A B E N; and the quantity saved is marked S M E N. As the area of each reservoir is supposed to be equal to twice the area of the chamber, the space which a certain quantity of water occupies in the chamber will be twice as high, or deep, as the space required for the same quantity of water in one of the reservoirs. Hence it follows, that

$$BP = 2\,PN = NK = 2x$$

and $CQ = 2\,QO = OS = 2y$

The whole lift A S, or

$$L = AC + CQ + QO + OS$$

or $L = 2x + 2y + y + 2y = 2x + 5y$

and likewise is $L = BP + PN + NK + KM$

or $L = 2x + x + 2x + 2y = 5x + 2y$

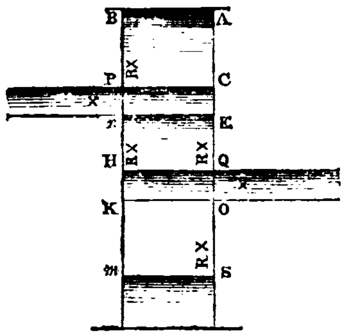
Hence $2x + 5y = 5x + 2y$

or $3y = 3x$

consequently $y = x$

The quantity and stage of water in each reservoir are therefore required to be equal.

Fig. 2.



Let the ratio which indicates how many times the area of the lock-chamber is contained in the area of each reservoir, be denoted by the letter R, so that when the area of the chamber is equal to 90 × 15 = 1350 square feet, let the area of each reservoir be expressed by R × 1350 square feet.

By examining the diagram fig. 2, it follows now, as a matter of course, that $OS = Rx = Km = Kn = QC = PB = AC$

By adding the different altitudes, which constitute the lift, we find

$$L = Rx + x + Rx + Rx = 3Rx + x = (3\,R + 1)x$$

an therefore, $x = \dfrac{L}{3\,R + 1}$

which expression gives the stage of water in the reservoirs, provided there are two. Without any further examination we can employ the following expressions as formulæ for the other required dimensions:—

1. The elevation of the bottom of the lower reservoir above the lower canal level, or $OS = Rx = \dfrac{R.\,L}{3\,R + 1}$
1. The elevation of top-water line of the lower reservoir above the lower canal level, $QS\ (R + 1)x = \dfrac{(R + 1)\,L}{3\,R + 1}$
3. The elevation of the bottom of the upper reservoir above the lower canal level, or $NM = 2\,Rx = \dfrac{2\,R.\,L}{3\,R + 1}$
4. The water saved, marked by the space MSEN, or $BAHQ = AQ = MN = 2\,Rx = \dfrac{2\,R.\,L}{3\,R + 1}$
5. The water used is marked by MSQH or $ABEN = SQ = BN = (R + 1)x = \dfrac{R + 1)\,L}{3\,R + 1}$

By examining the formula No. 4 for the water saved

$$\frac{2\,R\,L}{3\,R + 1}$$

we find that the saving increases with the ratio R, though not as fast. When we suppose $R = \infty$, that is, the area of each reservoir to be infinitely great, so that x, or the stage of water in each reservoir, will be almost reduced to nothing, the formula will then be

$$\frac{2\,RL}{3\,R + 1} = \frac{2\,\infty\,L}{3\,\infty + 1}$$

As the quantity 1 does not increase an infinitely great quantity,

it follows, $\dfrac{2\,\infty\,L}{3\,\infty + 1} = \dfrac{2\,\infty\,L}{3\,\infty} = \dfrac{2\,L}{3} = \dfrac{2}{3}\,L$

The greatest saving of water by two reservoirs is therefore equal to two-thirds of the lift of the lock. However, this much can never be gained in reality, though we can come near to it, without extending the reservoir too much, which would imply other inconveniences, as increase of cost, loss of time, and loss of water by greater evaporation.

The foregoing result of the maximum of water-saving will become also visible by mere examination of the diagrams, fig. 2. We see that when the stage of water in the reservoirs, or $x = PN = QO$, becomes, by being spread over an infinitely great surface, reduced to an infinitely small height, the points P and N, and Q and O, will be brought so near together, that they may be regarded as being reduced to the single points N and O, and therefore is

$$SO = OE = EA = \tfrac{1}{3}L$$

and the water saved $= SE$ or $BH = \tfrac{2}{3}\,L.$

For a given lift L = 14 feet, and R = 4, or the area of each of the two reservoirs to be equal to 5400 square feet, where the lock-chamber is supposed to be 90 × 15 in the clear, we find

$x = \dfrac{L}{3\,R + 1} = \dfrac{14}{3 \times 4 + 1} = \dfrac{14}{13}$	= 1·077 feet
The elevation $OS = Rx = 4 \times 1{\cdot}077$	= 4·308
The elevation $NM = 2Rx$	= 8·616
Water saved $= 2Rx$	= 8·616
Water used $= (R + 1)\,x$	= 5·385

By means of two reservoirs of 5400 square feet area each, a boat may therefore pass a lock of 14 feet lift, and not use more than 5·385 feet water, drawn from the upper level, where formerly, without reservoirs, a body of water of 14 feet height had to be used.

The following table shows how the quantity of water saved increases with the area of the reservoirs, supposing two reservoirs attached to the lock:—

For $R = \frac{1}{4}$ the water saved, or	$\dfrac{2\,R.\,L}{3\,R + 1}$ =	$\dfrac{2.\,\frac{1}{4}.\,L}{3.\,\frac{1}{4} + 1}$	=	0.285 L
$R = \frac{1}{2}$	„	„	„	0.400 L
$R = \frac{3}{4}$	„	„	„	0.461 L
$R = 1$	„	„	„	0.500 L
$R = 1\frac{1}{2}$	„	„	„	0.545 L
$R = 2$	„	„	„	0.571 L
$R = 3$	„	„	„	0.600 L
$R = 4$	„	„	„	0.615 L
$R = 5$	„	„	„	0.625 L
$R = 10$	„	„	„	0.644 L
$R = 100$	„	„	„	0.664 L
$R = 1000$	„	„	„	0.6664 L
$R = \infty$	„	„	„	0.6666...L

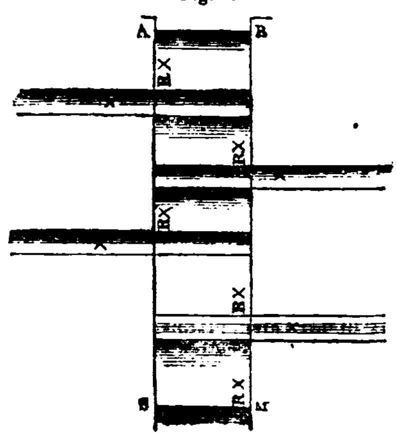
When only one reservoir is attached to the lock, the formulæ for all the required dimensions will be found:—

1. The water stage in the reservoir, or $x = \dfrac{L}{2\,R + 1}$
2. The elevation of the bottom of the reservoir above the lower level, is expressed by $Rx = \dfrac{R.\,L}{2\,R + 1}$
3. The height of the water saved is $= Rx = \dfrac{R.\,L}{2\,R + 1}$
4. The height of the water saved is $= (R + 1)\,x = \dfrac{(R + 1)\,L}{2\,R + 1}$
5. The maximum of water saved by one reservoir is found

$$= \frac{\infty}{2\,\infty + 1} \times L = \frac{\infty}{2\,\infty} \times L = \tfrac{1}{2}\,L$$

By means of one reservoir, therefore, nearly one-half of the lockage water may be saved in reality.

Fig. 3.



When four reservoirs are attached to the lock, as diagram fig. 3 shows, we find the lift

$$L = Rx + x + Rx + Rx + Rx + Rx = (5R + 1)x$$

and therefore $$x = \frac{L}{5R+1}$$

1. The elevation of the bottom of the lowest or the first reservoir above the lower level $= Rx = \frac{R.L}{5R+1}$

2. The elevation of the bottom of the second reservoir above the lower level $= 2\,Rx = \frac{2.R.L}{5R+1}$

3. The elevation of the bottom of the third reservoir above the lower level $= 3\,Rx = \frac{3.R.L}{5R+1}$

4. The elevation of the bottom of the fourth reservoir above the lower level $= 4\,Rx = \frac{4.R.L}{5R+1}$

5 The water saved is $= 4\,Rx = \frac{4\,R\,L}{5R+1}$

6. The water used is $= (R+1)x = \frac{(R+1)\cdot L}{5R+1}$

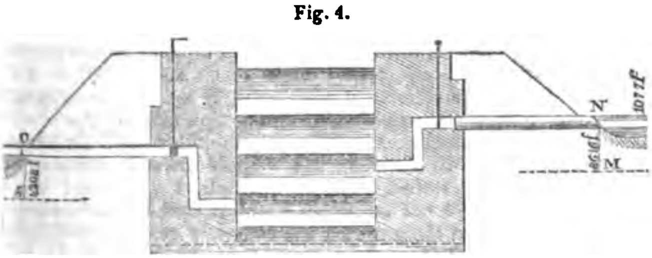
7. The maximum of water saved is represented by

$$\frac{4\,R.L}{5R+1} = \frac{4\,\infty}{5\,\infty+1}\,L = \frac{4\,\infty}{5\,\infty}\,L \qquad = \tfrac{4}{5}\,L$$

This demonstration shows that by means of four reservoirs attached to one lock, nearly four-fifths of the lockage-water that is wanted by a common lock, may be saved.

The annexed drawing, fig. 4, represents a cross-section of a lock of fourteen feet lift, connected with two reservoirs; each reservoir to have 5,400 supeficial square feet area. It is immaterial how the bottom of the reservoirs is formed, and it is necessary to have it below the level of the culverts, in order to prevent the dirt from being raised and carried into the lock-chamber. The bottom of each reservoir should be at least one foot below the mouth of the culvert, or lower, so that at least one foot of water remains in each reservoir, after the reserved water is discharged. The main object in constructing the culverts is, therefore, to have the points N and O, or the highest point in the bottom of the culverts so fixed above the lower canal level, that their elevation answers the expressions given by the foregoing formulæ.

Fig. 4.



The culverts in the lock-wall embankment are represented in the drawing to be of wood. The culverts in the wall itself must be constructed either in the form of rectangular syphons, or straight linear inclined, so that the mouth of the culvert of the lower reservoir opens into the lock-chamber, below the lower canal level; and the culvert of the upper reservoir enters the lock-chamber at an elevation equal to $2Rx$, above the former culvert. The reservoirs may be formed either by excavation or embankment, as the ground suits best. Where the natural ground is pretty level and square to the centre line, and the lock-walls are to be raised about one half their height above the natural ground at the middle of the lock, it requires but very little excavation and embankment to form the reservoirs. It often occurs that a depression in the ground, or a natural basin, near the lock, can be used to great advantage as a reservoir, requiring nothing but a little more culvert. Where there are two reservoirs, they must be located either, one on each side of the lock, or both on one side, as the ground suits best. In the latter case, the two reservoirs must be separated by a dam, either formed by excavation or embankment. The bottom of the reservoirs, and their side slopes should be covered with coarse gravel or slaty material, if such material can be had conveniently, in order to keep the water more fresh and clean.

The paddles are best placed in the upper parts of the culverts, as represented in the drawing, in order to prevent a great pressure of the water from the reservoirs towards the lock-chamber, and to keep the water safely shut up. The paddles should fit very close, and move in iron frames.

Whenever the supply of water is plentiful, the boats may pass the locks without using the reservoirs for saving a little more time. However, the excess of time which is required by using the reservoirs, is very trifling, and the passage can be effected with far less inconvenience and injury to the boats and locks, when the reservoirs are used, than when not. The objections which any engineer has against high lift locks, will be entirely removed by the construction of reservoirs. Reservoir-locks will be found very useful on slack-water navigation, where it is a great object to reduce the number of dams. If in such a case the river bank on the side of the lock offers no favourable opportunity, and not sufficient room, without removing great obstacles, as solid rock, &c. for the location of the reservoirs, the required width can always be obtained by shifting the lock a little more into the river, and by omitting the lock embankment. A bridge built along the lock-wall over the reservoir, will serve for a tow-path in this case. The attendance of a reservoir-lock requires no more skill than a common lock, as the state of water in the reservoirs and the chamber regulates itself, and the lock-keeper has nothing more to observe than to open the paddles, and to shut them as soon as the water-level gets settled. When the upper and lower levels are raised in time of a flood, the water will then occupy a different state in the reservoirs, and the contemplated saving of water will not be obtained exactly. In such a case, however, to save water is no great object, and the reservoirs will prove just as useful in all other respects.

THE NELSON MONUMENT.

Mr. Editor,—The unexpected decision of the Committee, to re-open the competition, unfettered by premiums, not only awakens the hope that now men who rank highest in the scale of art will deem it a prize worthy of their practised arms, and enter the lists with an earnest desire to distinguish themselves as artists and as Englishmen, but gives the public and the professions breathing-time, so that the soreness of the one, and the asperity of the other may be softened down.

I am quite old enough to recollect, that in the hey-day of exultation after the victory of Waterloo, the House of Commons came to something like, if not exactly, a vote that a large sum of money should be devoted to the erection of a public monument to commemorate it; and I am quite certain that desings for Nelson and Wellington monuments were advertised for in 1817. I know that designs were sent in, that they were kept some weeks, that artists were then desired to take them away, with an intimation that they might again be sent in, some three months afterward: and I apprehend you will find, upon inquiry, that the preminms were adjudged to Mr. Smirke and Mr. Wilkins. Why they were not executed your informant knoweth not, but mayhap those gentlemen will favour the public (if what I state be fact) with a view of them. If I mistake not, Mr. Flaxman proposed, as a fit monument, a colossal statue of Britannia, and published a pamphlet descriptive of the design, and of the mode in which he would construct it. These things are desirable to be known, and seen if it be practicable, that the public may ascertain whether art has receded or progressed since that day. Even did it no other service, it would caution critics to be more sparing of their censure, when such a man as Flaxman failed. But whether this can be done or not, in the absence of properly qualified persons, to undertake the task, will you allow one, who may rank as something intermediate between an amateur and an artist, and who has again and again, however feebly, considered the subject, quietly to state the difficulties which occur to him, that, if his opinions be well founded, the competing artists may not be spirit-broken by unfair and ignorant censure. I will first take the peculiarities which attend this competition. The Committee have never stated what kind of monument they think best fitted for the purpose. This alone is sufficient to paralyse the efforts of the most talented; for who can bring his mind efficiently to bear upon a subject which he is almost absolutely certain is but a will-o'-wisp? Sculptor and architect, each must fear that the sister art may be preferred, and consequently all labour bestowed upon the other will be thrown away. In emphatic, though common language, each feels that he is "working a dead horse." I do in my heart believe that few of the Committee can tell what they want, and am quite certain that not one of them can carry out his own ideas, so as even to satisfy himself: how then can it be expected that artists can remotely guess at what may perchance be something likely to suit their fancy?—Sooth to say, sir, I fear the selection is vastly like that of a lady in a cap-shop. Another difficulty is created by the situation which is pointed out for its erection. At first view it seems exceedingly easy to design a monument to be-set up in Trafalgar-square; but we first have to consider what is to be done with the ground, which falls from north to south some eleven feet at one end, and only about four feet at the other: and next, how a space about three hundred and ninety feet by two hundred and ten is to be laid out, so as, along with the monument itself, to grow into an appropriate picture; each feature bearing its part in the scene: and, supposing all this satisfactorily adjusted, we arrive at the questions, "What kind of monument is fitted for the site?"—"In what architectural style ought it to be?" or, if sculpture should be considered fitter, "Should it be broad and low, or should it be narrow and high?" The answers will be something like these—If narrow and high, the National Gallery will be cut in two—illustrating, it is true, one of Nelson's favourite manœuvres of breaking the enemy's line, but doing no great service to the building; and if broad and low, it so happens that even a height of fifteen or twenty feet would cut off about two-thirds of the portico of the Gallery; for if you stand upon the southern footpath, you will find that the trifling ridge of the ground shortens all persons walking on the footway at the Gallery, by the length of their legs. Then, as to architectural style: I have seen it suggested that it should assimilate with the surrounding buildings. Pray with which? There are but three buildings which can be said to have any style:—St. Martin's Church, the National Gallery, and Northumberland House;—the last is out of the picture, and consequently need not be cared for. The Gallery, whatever it may be in itself, is quite unfit to be worked up to in a naval monument; and St. Martin's Church need not be much heeded, for no style can injure that. Artists may erect whatever they please, that structure stands alone in its integrity, calmly scorning all the egotistical attempts around it. The questions, then, as to what style? and what kind of monument is fittest? can only be answered by going into a very difficult enquiry, involving a consideration of the distinct capabilities of architecture and sculpture, or of both combined; and how far they can be made to speak a widely understood language. There are certain simple forms prevalent among many nations, which, whether derived from the practice of one original stock, or inherent in the human mind, bring with them melancholy ideas. We, as it were, instinctively know a tomb; we feel that denotes a place of sculpture, and we reverence it as such:—but beyond that, it has no power of expression. To denote whether it be raised to commemorate a male or female, architecture has no resource but to call in the aid of sculpture.

There are certain other forms, which, although approximating to the sepulchral, yet appear to designate, not that human remains have there been interred, but that they have been set up in memorial of some event; but the architectural form conveys no idea to the mind of the event which is denoted, if sculpture have not, by her chisel, given to it a tongue. And there are other forms which, by their simplicity, solidity, and calmness, appear evidently intended as sacred places appropriated to the worship of the Deity. Architecture can erect temples, memorial stones, and tombs, with little risk of her meaning being misunderstood; the forbidding gloom of a prison, or the festive gaiety of a banquetting-room, can be characterized by her to some certain extent; but how, as some seem to expect, she is so forcibly to depict the qualities of the human soul, that all men are at once to understand the structure commemorates a hero, is far beyond my comprehension—it is in fact beyond her power. From the stone of Bethel set up by Jacob, from the obelisks raised by the Egyptian kings, down to the loveliest conceptions of Grecian art, and thence onward to the military columns of the Romans, and of the Place Vendome, all have required either the aid of inscription, or of sculpture, or of tradition, to point out what they mean; and where these have failed, as in the case of the Egyptian obelisks, there we stand gazing in utter ignorance. To come closer home.—Does the Monument on Fish-street-hill, divested of its sculpture and inscription, by aught in its aspect tell us that it memorializes the burning of London? What does the column in Waterloo-place tell us? What do all the columns and monumental structures over all England, set up in commemoration of Nelson, tell us of his character? The column of skulls piled up by the Tartar chief, unequivocally spake of an enormous slaughter; the projected Russian column of cannons and mortars might be supposed in some way to denote a victory, yet even these are not, strictly speaking, architecture; they partake more of the character of sculpture in its most barbarous form. But by what magic genius has architecture been made "trumpet-tongued," to tell of Nelson, the energetic, the fearless, the affectionate, the open-hearted, the generous, the devoted, the heroic? We may indeed be told of breadth, and height, and strength, and massiveness, as calculated to denote the warrior chief; but alas for the National Gallery if any one of these demons be conjured up, and woe to the paltry sum which is said to be available for the purpose. Sculpture has a more extended range, and greater power than her sister art, for she can call in the expression of the human form, and add explanatory embellishments in her own pictorial language; but even her power is limited, and needs written language to tell the whole tale. It is in her power to erect a statue, which, without being much beyond the human size, nay, it may even be very much below it, shall impress the beholder with the most sublime ideas of the being it represents. It is in her power to compose a group of statues, which shall, with the most impassioned eloquence, spell-bind the soul. It is in her power, by a well-conceived line of relievo, to carry out the whole of a continuous history; she, like Painting, can, to a vast extent, realize the poet's seraph-song, and bid the dumb stone start into life; but, notwithstanding all this her strength, there is a limit to her resources—she has one source of weakness, and that, I fear, will render all her art unavailing if she attempt to erect an isolated monument. All her works are necessarily and in themselves only embellishments, are only appurtenances: however firmly cramped to a building, they form no part of it; however deeply rooted in the earth, they are still nothing but moveables; but, independent of this, they are not calculated to be viewed from more than one, two, or three points advantageously. Owing indeed to the absolute perfection of all the Almighty's works, any correct imitation of the naked human figure, or of any animal, singly and in itself, must be beautiful, view it from any point; but when brought together in a group, so as to tell a story, the insufficiency of art is manifest. Sculpture, in fact, can only make pictures in stone, wood, or other material; those pictures, when so placed, as that the spectator can only see them in front or a few degrees sidewise, especially if within a building, and the quantity, colour, and direction of the light, be skilfully adjusted, may be made to produce the most wonderful effect; but, in an isolated monument, and that in the open air, it is altogether different. However well-composed the grouping, however grandly conceived the attitudes, and however admirably calculated to convey the artist's meaning, all its effect is likely to be marred, even if it be not made absolutely ridiculous, by the spectator taking it in flank, or viewing it from behind. It is in vain to say that the spectator ought not so to do. In its very nature an isolated monument should be calculated to look well from any and from every station; and therefore, if I be right in my showing, a group of sculpture only is not available for the Nelson monument.

If so, I apprehend the conclusion will be that the proposed erection must either be a statue (not a monument) more or less colossal, standing on a pedestal or block, more or less high, and more or less embellished, and those embellishments, made by the artist, to bear an important part in his picture; or an architectural monument, decorated with such sculpture as may be necessary, clearly and fully, and yet without confusion, to tell, as far as art can make it tell, the wherefore of its erection.

The mere statue would, in itself, be no insuperably difficult task. It must be colossal, or in a space of some five hundred feet in width, from house to house it will be lost; it ought to be calm and dignified, and especially no violent action ought to be attempted, or it will be ridiculous. An architectural monument is by no means so easily to be composed: it will require more ability than falls to the share of most men, so to unite architecture with sculpture, that neither shall unduly predominate, but both distinctly and forcibly assist in forming a fit basis for the hero's statue, for such, after all, I apprehend it must be. The object will not be attained unless that be the leading or ultimate feature, and the great art will consist in gradually leading the eye upwards until it rest upon that main object, without being distracted in its progress by intrusive ornament, and without finding the structure broken into steps as it were, and not forming one integral work, but so many separate pieces piled upon each other; or, should the artist deem a comparatively low erection more appropriate, it must not be so broad as to stretch beyond the field of distinct vision. If, however, breadth be deemed desirable, then can it be little more than a series of terrace steps, else will the National Gallery be destroyed. If height be deemed requisite, and it be made square, polygonal, or circular, it will either resemble a pedestal or a church-tower, or castle-turret, and no profusion of decoration can divest it of one or other of those characters, unless, indeed, it be made so high as to be columnar; and much I think that any desire to make it an architectural object must content itself with the columnar form. As to the kind of column, I apprehend that only the Ionic is inappropriate, for that is not calculated to stand alone, its fronts and flanks being dissimilar. Much has been said against Corinthian columns, but I think with very little justice or good taste. It is true that the substitution of the Jupiter Stator column for the Doric of Fish-street Hill, is no design at all, any cabinet-maker's apprentice could have done as well; but I think it may be possible even to make a Corinthian column form a very appropriate object, yet it must be ably treated, and made to seem what it really will be, nothing more than a standard to support a statue. Concluding then that the proposed memorial must either be a column surmounted by a statue, or a statue standing upon a block, or an architectural pedestal, the fit style of decoration is next to be considered.

A column of any order admits of but little ornament except upon its pedestal, and even there it is not peculiarly fitted to show advantageously. Mayhap the spiral reliefs on the Trajan column are the fittest for a military structure; but, independent of the cost, they could not be made very distinctly visible at more than a hundred feet in height, and in a London atmosphere not so high as that for any long period. But any attempt to surround the base of a column with either standing or sitting figures must end in its appearing at a distance, like an illumination candle stuck in clay. It is a ridiculous comparison I allow, but I cannot divest myself of it. The base of a statue will, if I think rightly, be capable of much and very appropriate decoration. I would certainly eschew all Neptunes, Britannias, and Victories; all very well in themselves, but much too common-place for such a work. Should groups of statues, or pannels, or other recipients of bassi-relievi be introduced, I strongly think that the great art will be, as much as possible, to make them, as it were, grow out of the masonry, in suchwise as to appear an integral portion of the pile; so that, although they might indeed be removed without injury to the stability, yet still that taking them away should detract from the completeness of the work. There should be no flutter, no pinnacling in the outline; all should be in calm and dignified repose; and the whole mass be such as that, while at a distance its harmonious proportion should delight, upon a nearer view its sculpture should be instructive and interesting, and upon the closest inspection found to be wrought in the highest style of art.

If I have rightly read the relics of ancient art, such was their principle. The same correct principle will, upon careful consideration, be found to prevail throughout styles, in many respects as wide asunder as the antipodes; but wherever it has prevailed there will grandeur and beauty be found combined.

I feel the subject has led me far beyond my original expectation, so far indeed that I fear few will care to follow it; but if they do, I think it will be felt that of all difficult tasks the composition of an isolated monument is incalculably the most difficult, and that it will be extremely unfair harshly to censure failure in such an attempt.

It is to be recollected that all competitions are in themselves tasks; that in such a competition as this the mind is, as it were, overwhelmed with the greatness of the character of Nelson, and overreaches itself in striving to grasp at an imaginary vigour of expression. It is also to be borne in mind, that if such men as Nelson and Wellington arise but with centuries between them, artists equal to the task of commemorating their deeds are of similarly rare growth. The enrapt spirits of Homer, or Æschylus, or Milton, might shadow forth their achievements; the mighty genius of Flaxman could almost soar a kindred flight, but even he failed in commemorating Nelson, marvellous as were his compositions on other subjects. Even if, in this second competition, not one of the designs should be fitted for the purpose, it will ill become critics to censure the failure so harshly and unfeelingly as has been done. They, as authors, must be aware that the happiest thought does not come for the seeking, that it is often the lightning glance from heaven, darting when least expected; and common charity should teach them forbearance from unmerited insult. I have already said that I do not believe any one of the committee can carry out his own ideas of what Nelson's monument ought to be, even if he be able to form any idea at all. I fearlessly say the same of others, and would advise them to think so, at least until they have fairly set to work and wrought out such a design as shall far excel those of the men they sneer at.

I know my own weakness, my own inability, and can therefore make large allowances for failure in a task so difficult; still do I not despair of the genius of English art, and shall most cordially delight in the success of any of my countrymen.

I have the honour, Sir, to be
Your constant subscriber,
OMEGA.

THE ROYAL EXCHANGE.

Sir,—The system pursued of late years in the management of architectural competitions, has been attended with manifold evils, and, beyond all doubt, fraught with gross and palpable injustice. Hastily and inconsiderately commenced—under the control of persons unfitted to sit in judgment on the various designs referred to their decision, they have in too many instances been attended by results, injurious to the best interests of Art,—unfair and unjust to its professors—and unfavorable to the public at large.

In making these remarks, I do not of course, intend to attack the principles upon which competitions are based,—properly conducted, their tendency is unquestionably, not only to call out the talent and genius of the experienced artist; but to rouse a spirit of emulation in the young professor, and encourage that rising merit, which without such a stimulus would remain undeveloped, and without such a means of exercise, unknown and unappreciated. But the thing which I wish most anxiously to press on the attention of the profession at large, through the medium of your columns, is mainly this,—The extreme defectiveness of the present system; the total want of security, which there is under its operation, that fairness and impartiality will be strictly observed towards all, and the urgent necessity which consequently exists for a searching and efficient remedy.

It would be needless to go into any lengthened proof of this assertion; the voice of public opinion has frequently been most unequivocally expressed in denunciation of the present mode of conducting architectural competitions; and, to mention no others, the whole proceedings connected with the new Houses of Parliament, speak with sufficient clearness to all, by way of warning. Upon that point, however, it is not my intention to enlarge; and I only make the allusion in order that architects may gather from the recollections and experience of the *past* a valuable lesson for their guidance and direction for the *future*.

Architects have been invited to send in plans for re-building the Royal Exchange, and as a preliminary, they are compelled to pay one pound to obtain the requisite instructions. I pass over the unreasonableness of this demand, which makes all the competing architects, except the successful three, actually pay one pound, in order to have the opportunity of embarking their time, talents, and labour, on what *must* prove to them *unrequited exertion*. I have more important considerations to urge, of paramount and leading interest, to all who intend to compete for the proposed edifice.

And I ask them plainly, what guarantee have they, that the present competition will be conducted on the principles of fair dealing, impartiality, and justice? On what grounds are they convinced (for the act of entering the competition shows that they have that conviction) that it is the intention of those upon whom devolves the duty of adjudication, to go into a strict and searching examination of their designs; making their decision according to *merit, and merit alone;* and selecting only those, which while they conform to the instructions, are distinguished alike by the beauty of the exterior *facade* and the convenience of the internal arrangement. I say, deliberately, that at present, there exists no such guarantee, either in the wording of the published advertisement, or the printed instructions of the Gresham Committee: and yet, unless architects can obtain from the authorised parties some pledge more explicit—some statement more distinct—some promise more definite, it is really madness in any one who values his time, station, or character, to embark in so uncertain a venture, when, perhaps after having spent months of concentrated effort, together with a vast amount of anxiety, fatigue, and money, in getting up his designs, he may be coolly superseded, by some favoured rival; who, without being able to lay claim to any extraordinary degree of talent, yet possesses a larger amount of personal interest and local influence.

What then is the duty of architects at this juncture as professors of a liberal art, and men of spirit and independence? Undoubtedly it is to bestir themselves, and act with unanimity and firmness.

Should they accept the present indefinite invitation, which contains no guarantee beyond that which the Parliament House Competition included, and which will probably—unless something be done,—be productive of dissatisfaction to all parties concerned, and disappointment to the public; they will have none but themselves to blame, in having, contrary to repeated advice, and with all the experience of former competitions before their eyes, tamely submitted and acquiesced in the terms proposed, when by the adoption of a more vigorous course of conduct, they might have effected an altogether different result.

In a report upon public competitions, lately published by the Royal Institute of British Architects,—every architect is recommended, individually, to address in writing to the Secretary, or other authorised party, the most searching inquiries upon every doubtful or indistinct point, and not to rest satisfied with any answer which fails to place everything necessary to be known, in the clearest point of view. This mode, however, seems open to many serious objections,—as it would not only give the Secretary of the Gresham Committee a great deal of trouble to answer the innumerable queries that would be put to him by individuals: but also, being in all cases strictly private, no information would thereby be afforded to the profession generally, of the intentions of the Committee,—which information, if it could be obtained, might be a *bonâ fide* pledge on their part, of their determination to act with strict fairness and impartiality.

Let then the architects—as the only alternative—convene a public meeting; let the leading members of the profession attend: let them delegate a certain number of their most influential men to request of the Gresham Committee, a fuller and more minute explanation of their intentions in reference to the Exchange Competition; let them inquire who are to be the judges?—Whether a strict adherence to the instructions is a necessary preliminary on the part of the architects, to secure his plan, *an inspection?*—Whether all designs, which cannot be executed for the sums estimated, shall be laid aside?—Whether a public exhibition shall *precede* as well as *follow* the decision of the judges?—And, whether the author of the chosen design shall be allowed to superintend the erection of the work, provided his standing in the profession, and experience as an architect, entitles him so doing? And, till these inquiries are *satisfactorily answered*, let it be the *unanimous* resolution of the Architects of England, that *they will not enter into the present competition—that they will not lend it their sanction—nor give it the benefit of their talents and support.* And if they thus act firmly and unitedly, a better system of things will be ultimately adopted, and the cause of truth and justice must eventually triumph.

In conclusion, I have only to add, that I feel quite assured, that some such proceeding as this, would not only tend to raise British artists in the estimation of the public—and secure, in a great measure, a fair and free competition—but would also induce many of the leading architects to contribute, who at present—being fearful of unfair dealing—have no such intention; and would moreover be the means of obtaining a design for the Royal Exchange, worthy of the metropolis it is to adorn, and an honour to the taste and genius of the age.

I remain, Sir, your obedient servant, and constant reader,

April, 1839. AN ARCHITECT.

FLOATING HARBOURS OF REFUGE.

SIR—I do not recollect that I have seen any observations in your interesting work relative to the principle of floating harbours or breakwaters, and I am led to notice the subject from having read with great pleasure the article by Hyde Clarke, Esq. C. E., upon Isolated Harbours of Refuge, in your last number.

No question can exist upon the advantages of natural harbours as described to be at the island of St. Michael, and I am induced to think that observations made upon Porto do Ilheo, led Admiral Sartorius to think of making a floating harbour at Terceira, upon which he corresponded with the patentee of the floating breakwaters, but which his expedition from the Azores most probably prevented his attempting to carry into execution. The principle of harbours of refuge is advantageous in proportion to the practicability of carrying the protections they afford into deep water. The construction of masonry, or the accumulation of stones, is expensive in a progressive proportion to the depth of water—hence the saving attending floating substances secured so as to form harbours in deep waters must be very great.

The successful experiments which were tried in 1824—though discountenanced by the Admiralty on account of the apprehension that they were favourable to smuggling—demonstrated that no objection ought to be raised against a floating harbour, if composed of rafts situated in a position where they could never ground. Julius Cæsar found out their advantage when he employed them, as described in his Commentaries, as follows:—

"Cæsar sat down, on the 9th of March, before Brundusium, with six legions, three of which were composed of veteran soldiers, and the rest of new levies drawn together on his march. He had sent Domitian's troops directly from Corfinium towards Sicily, not caring to bring them near Pompey's quarters. The Consuls had sailed on the 4th with thirty cohorts, and there were still twenty in the town with Pompey. Nor was it certainly known whether he continued there for want of shipping to transport his troops, or with the design to keep possession of Brundusium, that he might be master of the whole Adriatic Sea, the farthest parts of Italy, and the country of Greece, in order to make war on both sides the gulf. Cæsar having lost all hopes of an accommodation, and fearing that it was his intention to keep footing in Italy, resolved to push the war with vigour, and to deprive him of the advantages he might reap from the port of Brundusium. The following works were contrived by him for this purpose. He carried on a mole on each side of the haven where the entrance was narrowest, and the water shallow. But as this undertaking could not be carried quite across the port by reason of the great depth of the sea, he prepared double floats of timber, thirty feet square, which were each secured by four anchors, to enable them to resist the fury of the waves. These, which were to extend all the way between the two moles, were covered over with earth and fascines, that the soldiers might pass and repass with ease, and have firm footing to defend them. The front and sides were armed with a parapet of hurdles, and every fourth float had a tower of two stories, the better to keep the enemy's ships at a distance, and to guard the work from fire and the shocks of vessels."

I have not the advantage of having seen the Port of Brindisi, but the extract sufficiently explains the nature of the works. There are numerous positions on our coast which are well suited to such an operation, and if a harbour were constructed with stone jetties in the shallow water, and floating breakwaters moored seaward, there can be little doubt of the purpose being effected.

I have the honour to be, sir,

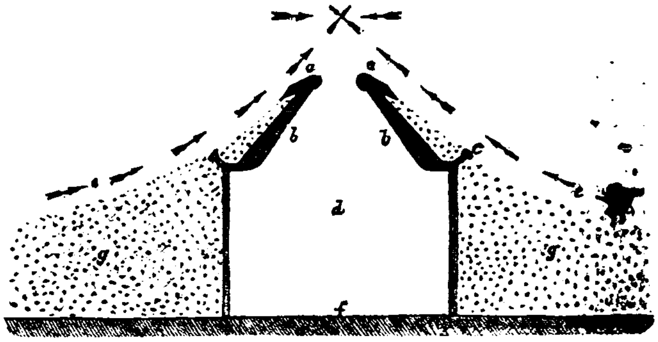
Your humble servant,

AN ARCHITECT.

[The employment of floating harbours is very important, and by means of Mitchell's screw moorings might be applied in many positions.—EDITOR.]

HARBOURS OF REFUGE.

The counter run. The true run of the tide.



The Line of Coast on Shore.

aa, The horn-work.—*bb*, Pier-heads.—*cc*, Jetties.—*d*, Harbour.—*ee*, Bays. —*f*, Quay.—*gg*, Beach or Shingle.

SIR,—Seeing by the public papers that the Lords of the Treasury have sanctioned the constructing of Harbours of Refuge for her Majesty's smaller vessels of the Royal Navy, against the easterly gales on the coast of Essex, Suffolk, and Norfolk, in these works of the government, it is not intended to prevent private companies from making inner basins or inland harbours.

I have sent you a Plan, which I shall feel obliged if you can find room for in your next Journal: it is entirely new, and adapted principally for a coast which is composed of beach or shingle, and their construction would be about half the cost of harbours as they are now built. By this plan you will perceive that it is in the formation of the Pier-heads which locks up a body of beach or shingle against their sides, and causes the tide to be embayed by whichever pier it sets against; this, with the run of the true tide, would propel all the surplus beach or shingle which was in motion several fathoms out seaward beyond the pier-heads, and prevent any bar forming at its entrance or around it; a large body of beach, &c., will be accumulated at the foot of both sides of the harbour, and form the best barrier in protecting it. These harbours of refuge would be very beneficial around our coast, for the protection of our seamen, ships, and commerce; and an encouragement to our fisheries, independent of the protection it would give, or afford, to her Majesty's steam-vessels.

I am, Sir, your humble servant,

W. KINGSFORD.

Buckland, near Dover,
April 10, 1839.

BRITTON'S DICTIONARY.

SIR,—There is a homely proverb, which says, "the proof of the pudding lies in the eating," and it applies exceedingly well to Britton's Dictionary of Architecture, for whatever commendation the book may have obtained as soon as it comes to be fairly tested it will be found most egregiously deficient and defective, nor least of all so where information is most wanted, and where there was, consequently, ample opportunity to supply what previous works of the same kind had neglected to do. Undoubtedly it was perfectly optional on the part of the compiler to limit its plan as he pleased, or as might best suit his own convenience, however he might, by so doing, lessen its usefulness; still, whatever he had once adopted, he ought to have considered himself bound to adhere to consistently throughout. Now this, most assuredly, he has not done with regard to terms connected with classical architecture; since, besides being very insufficient and unsatisfactory in themselves; what there are, amount to no more than a meagre sprinkling of them, and precisely of those of which a mere explanation will hardly be sought by any one. It avails not to say that this Dictionary is intended to elucidate chiefly the architecture of the middle ages, such excuse being altogether nugatory, and almost equivalent to saying that the other terms—at least such of them as occur, are brought in, not because at all called for by the professed object of the book, but merely to swell it out, and to induce persons, upon a hasty inspection of it to imagine that it is far more copious and complete than its title gives it credit for being.

What, however, I most strongly protest against is the disingenuous and even trumpery artifice, for I can give it no better name, of pretending to give the corresponding terms in other languages, but invariably omitting them in the case of strictly technical words, whose meanings are seldom to be ascertained from consulting French, Italian, or other dictionaries; whereas had they been uniformly introduced, and also indexed, so that their English meanings might be instantly ascertained, the Dictionary would have been really useful for reference; even in reading foreign architectural books. What is not the least surprising is that these omissions extend even to such terms as belong peculiarly to Gothic architecture, for instance, "corbel," "hood-moulding," "mullion," "pendant," "spandrel," "transom," "tracery," in fact to almost all the terms of that class, although more especially required, because for the foreign ones which answer to them, it is almost useless to look in dictionaries. I lately met with the German terms "Dobel," "Glaspfalz," and several others (of which I may at some other time, perhaps, send you a list, as some of your correspondents may possibly be able to explain them) they evidently refer to parts of Gothic windows, but what may be their precise meaning I cannot say, nor does Britton's Dictionary afford me the slightest clue, for in vain have I there referred to all the English terms, with which the ones above-mentioned are at all likely to correspond.

On the other hand, of what use is it, I ask, to give the French, Italian, &c., of such general terms as "architect," "house," and a hundred others, which the commonest dictionaries supply, and for which no man, who at all understands the language in which they occur, can have occasion to refer to a dictionary at all. The truth is all that Mr. Britton has done in this respect amounts to more than idle, and I may add, exceedingly silly parade, since nearly all the foreign words are more or less disfigured by blunders that convict Mr. Britton; of being utterly ignorant of the languages themselves, some of these blunders may be errors of the press, but then it is evident that he was unable to detect them, because an author's attention is always more particularly directed to such matters as foreign words or quotations, it being there that compositors are most likely to make mistakes. In addition to blunders of the above kind, which are so numerous, as to be on that account alone quite disgraceful, there are others which prove more completely that he compiled without the least understanding what he was copying. Should he ever have any German or French readers how will they stare at finding "raum," and "chambre," given as the words respectively answering to our English one of room. A Frenchman would, I conceive, more frequently than not employ the term "piece;" certainly in speaking of a building architecturally, while if a German were to make use of the term "raum," he would not be understood at all. The above is far from being a solitary instance of the kind, but it will serve to show what reliance is to be put upon a dictionary, the compiler of which speaks, in his preface, so '*d'haut en bas*,' of other works, of which he has, nevertheless, availed himself so largely, that to them he is indebted for almost all that is of any value in it.

ARGUS.

ROYAL EXCHANGE.

"The Joint Gresham Committee beg to inform Architects who are desirous of submitting Designs for the intended Royal Exchange, that they may obtain a Lithographic Plan of the intended Site, with other particulars, upon payment of *one pound*, at the office of the Surveyor to the Committee, Mercers' Hall, London."

A very great delay has certainly taken place asoto the progress of the Exchange itself, but the several committees, in their laudable anxiety to keep the public amused, have either by themselves or their friends, appropriated the site to a temporary shrine of Pasquin. Lately, some wag amused himself with a caricature representing the site to be let, until wanted, for a Royal Exchange; but now we are indebted to the joint Gresham Committee for a much better burlesque.

At the head of our article will be found the announcement on what terms architects can obtain the necessary information; and that for the modest disbursement of a sovereign, they can have *a lithographed plan of the site, and the printed particulars*. The modesty of these terms cannot be sufficiently lauded, for we doubt if even any printseller could have contemplated such profits of more than cent. per cent. At any rate, for 50*l*. a thousand copies of the plan might have been struck off, and as many of the proposals; and supposing all these to have been applied for, still it would have made but 30*l*. The Gresham Committee, however, "a poor but honest man, my Lord" could not afford the expenditure of such a sum, and still less could it resist the temptation of pocketing the difference from the two or three hundred competitors.

The paltry meanness of such a shabby imposition is as contemptible as it is dishonest, and it is equally a gross dereliction of public duty, and an offence against the conventional laws of common courtesy. Do not the members of the Gresham Committee know, that instead of conferring a favour that they are certainly cutailing a heavy expense upon ninety-nine out of a hundred competitors? or can they consider themselves as acting with common justice towards persons who are already exposed to a heavy outlay? Many individual architects will be put to a much greater expense than the Gresham Committee merely in preparing their drawings, independently of the loss of time consequent upon their attention to them. There are sacrifices made it is true for a personal object, but still as certainly conducive to public advantage, and almost as incontestibly productive of individual loss.

The commodities supplied for this nefarious bargain are admirably in keeping with its other details, and are as remarkable for their incompleteness as they are for their worthless character. There are no sections of the streets or sewers in the neighbourhood, so as to show the depth necessary to go for foundations, and no information as to the comparative heights of the neighbouring buildings, which must exercise an important influence on the design. To an architect in the country these must be serious impediments, and the very formation of the site is beset with sufficient obstacles not to require the intervention of more. The Globe Insurance-office, however new, ought to come down, so as to leave the site unrestricted to its present bag-like appearance. It may be very doubtful also, whether the site selected for the perspective view is positively the best, and whether it might not have been preferable to have made the elevation fronting the Bank the principal façade.

We regret to see that this print-shop is set up in a place where last of all we should have expected to see it. It is melancholy that one of the most respectable members of the profession, also a Vice-President of the Architectural Society, should have allowed himself to be made the medium in furthering such an insult and an imposition. It was his duty towards the profession, so far from fostering such a job, at once to have resisted it, and to have denounced to the Committee such a barefaced insult to his brethren.

We think that there is a laxity in the operations of the Royal Institute of British Architects, or, taking such an interest in competition as they assume to do, they should have been more active with regard to this edifice. Uniting among themselves many of the most eminent architects of the empire, they ought to take a decided part in the regulations of competitions, on which, by the bye, their last report is by no means satisfactory. To exercise a beneficial influence on public opinion they must be more decided; and one of the best steps they could take on the occasion of a competition, would be to send a deputation to the Managing Committee to effect a proper arrangement of the manner and terms of competition.

Below, we give a copy of the regulations of the Gresham Committee, and at our office may be seen a copy of the plan from which any member of the profession is at liberty to take a tracing. It will always be our endeavour to resist proceedings injurious to the profession, from whatever quarter they come; and we call upon our readers to show an equally strong opposition to an attempt at imposition so barefaced and so iniquitous.

Resolutions of the Gresham Committee, as Instructions to the Architects.

1. That architects be invited to offer designs for the re-building of the Royal Exchange in general competition, and that premiums be offered for three designs adjudged by the committee to be the best.

2. That the lithographic plan shows the site approved of by the Lords of her Majesty's Treasury, and that a copy of such plan, with the resolutions and instructions, be given, on the payment of *one pound*, to any architects wishing to furnish designs, on his applying at the office of the Gresham Trust, Mercers' Hall.

3. That the new building be of the Grecian, Roman, or Italian style of architecture, having each front of stone of a hard and durable quality,

4. That the designs offered by the several candidates must all be drawn to the same scale, viz., ten feet to one inch and a half, exhibiting the plans of each story, with an elevation of each front, and longitudinal and transverse sections, together with an interior elevation. That a copy of the lithographic plan be also sent by each candidate, drawn in Indian ink, to the same scale as the designs, and showing correctly the outline of the proposed building, the site thereof tinted red, and of all adjacent buildings, in Indian ink; that all the drawings sent by each candidate shall be tinted with brown Indian ink only, and that no perspective drawings of the design shall be received, except two, which shall be taken from the situations specified on the lithographic plan to be delivered to the parties.

5. That no model, sketch, perspective, or coloured drawing (save two such perspective drawings as are described in the previous resolution) shall be received.

6. That a specification be required to accompany each design, giving a general description of the building, and such other information as cannot be clearly shown on the drawings, stating also what stone or other materials are proposed for use in the different parts of the building, and specifying particularly the estimated expense of carrying the designs into execution in the most substantial and complete manner in every respect for occupation, the expense not to exceed 150,000*l*.

7. That no seal, motto, or other distinguishing mark be attached to any of the drawings or specifications, and that any drawing or other paper having such mark shall be rejected.

8. That the designs be delivered at the office of the Gresham Trust, at Mercers' Hall, on or before the 1st of August next; that each design have a number attached to it on delivery, and that a corresponding ticket and number be given to the person delivering the same.

9. That a sealed letter be delivered with each design, containing the name and address of the candidate, the same to be returned unopened to unsuccessful parties.

10. That for the design to which the Committee shall award the first premium the sum of 300*l*. shall be given; that for the second design the sum of 200*l*.; and for the third the sum of 100*l*. The successful competitor to whom the first premium is awarded shall not be considered as having necessarily a claim to be entrusted with the execution of the work; but if not so employed, and his designs are carried into execution, a further sum of 500*l*. shall be paid to him—the Committee retaining possession of all the drawings for which the premiums have been given.

11. That if reasonable doubts should arise in the minds of the committee as to the practicability of carrying into execution the successful design for the amount of the estimated expense of the building, the committee shall be at liberty to call upon the party to give sufficient and satisfactory proof of the accuracy of the calculations, and to withhold the premium and reject the designs unless such proof be furnished.

12. That the following further instructions be adhered to by the architects in preparing their design:—

First—That no part of the several fronts is to be advanced before the line shown in the lithographic plan, and coloured red, the same being considered as the extreme projection of the stone-work at the level of the pavement.

Second—That the basement of the building be appropriated to vaults, cellars, strong rooms, &c.

Third—That the ground-floor be appropriated to shops or offices, so far as the same can be adapted to the design.

Fourth—That each part of the building proposed to be held as a distinct tenement is to be completely separated by brickwork or other materials equally fireproof from every adjoining part, on either side, or above or beneath it.

Fifth—That the area or space for the meeting of the merchants and others be about 20,000 superficial feet, of which about 7,000 be open.

13. That the statement annexed hereto of the proposed dimensions of the rooms and offices, &c., required, be adhered to in the designs; but as the several measurements which have been given are stated with a view of affording a general guidance to the architects in preparing their plans, not restricting them to the precise dimensions given, the architects will be at liberty to suggest such forms for each room, office, &c., as may appear to them most convenient, observing that the superficial areas should not be less than the sizes specified. They are also to provide in the remaining portion of the building as many additional offices as possible, to be let as distinct tenements.

The following rooms and offices are required:—

	ft.		ft.		ft.		ft.
One room	125	by	40	Two rooms .... each	19	by	14
One do.	60	by	16	One room	60	by	30
One do.	94	by	60	One do.	40	by	20
One do.	38	by	32	Two rooms ..... each	19	by	15

In addition to the above, not necessarily on the same story, one room, a kitchen, and a bar, containing together about 2,300 superficial feet.

The above is exclusive of a staircase, or staircases, lobbies, landings, water-closets, urinals, washing-rooms, walls, and partitions; also strong rooms on the basement.

The following rooms and offices are further required:—

	ft.		ft.		ft.		ft.
*One room	50	by	24	One room	30	by	20
*One do.	10	by	10	One do.	16	by	20
*One do.	15	by	20	One do.	15	by	20
*One do.	21	by	20	Four rooms ...... each	13-6	by	13
*One do.	15	by	12	*One room	10	by	10
*One do.	40	by	25	One do.	16	by	20
One do.	15	by	20	*One do.	17-6	by	20
One do.	15	by	20	One kitchen	12	by	10
One do.	20	by	20	One room	15	by	12
One do.	28	by	20	*One do.	25	by	10

Those marked * not necessarily on the same story.

The above is exclusive of a staircase or staircases, lobbies, landings, water-closets, urinals, washing-rooms, walls, and partitions; also strong rooms on the basement.

The following rooms and offices are further required:—

	ft.		ft.		ft.		ft.
One room	50	by	30	One room	30	by	21
One ditto	21	by	20	One ditto	40	by	21
Two ditto .... each	30	by	21	One ditto	21	by	20
One ditto	35	by	21	One ditto	21	by	18

In addition, three waiting-rooms, water-closets, and washing-rooms.

The above is exclusive of a staircase, or staircases, lobbies, landings, urinals, walls, and partitions; also strong rooms on the basement.

14. All designs will be excluded from the competition which are not in strict conformity with the preceding instructions in every respect.

N. B.—The architect of the Gresham Trust and his partner do not intend sending in any design.

RAILWAY, CANAL, AND ROAD TRAVELLING IN FRANCE.

The current estimates of the French Board of Works, which amounted to 40,000,000f. (1,600,000*l*.) in 1831, were raised to 45,000,000f. (1,800,000*l*. in 1837. This very considerable sum is devoted to the maintenance of the roads, bridges, and canals. An engineering overseer, who is attached to the administration of each department, directs and manages the works to which the money is applied. Besides these current estimates, a law, passed in 1833, gave rise to a vote of extraordinary supplies for public works, which provides for the more important repairs, the completion of undertakings still unfinished, and the construction of new lines of communication. This additional vote, which has been increased by similar laws, passed in the years 1835, 1836, 1837. and 1838, has now reached as large a sum as 350,000,000f. (14,000,000*l*. sterling.) Out of this fund the Chambers have granted 27,000,000f. for the improvement of harbours; 64,000,000f. for the amelioration of the river navigation; 63,000,000f. for the completion of canals began in 1832; to which has been added a vote of 85,000,000f. for a lateral canal to Garonne, between Toulouse and Bordeaux, and a junction canal between the Maine and the Rhine; lastly, the high roads have obtained a grant of 107,000,000f. The *conseils-generaux* in the various departments have voted for the extension of the departmental roads not less than 60,000,000f. When the works now undertaken, and in progress, are finished, there will be in France nearly 8,000 leagues of high roads of the first class *(routes royales)*, 8,500 leagues of high roads of the second class *(routes departmentales)*, and 850 leagues of canals. An unbroken line of internal navigation will be opened from Havre to Marseilles, and from Strasburgh to Havre. The principal deficiency in the means of communication in France is celerity. The steam-boats have great difficulty in ascending against the stream of the larger rivers. The only canal on which the system of fly-boats has been borrowed from the Scotch and English canals, or, at least, borrowed with success, is the Canal du Midi, from Toulouse to Cette. The mails, indeed, are transported at an average speed of three leagues an hour. The use of the telegraph is confined to the business of the Government. The railroads which have been executed, up to the present time, are inconsiderable, and the railroads at this moment in execution are for very short distances, their whole united length not exceeding forty four leagues.

CALEDONIAN CANAL.

Copy of MR. WALKER'S *Report to the Board of Treasury.*

Instructions.—In compliance with the instructions contained in your letter of the 28th December 1837, after the accident to the lock at Fort Augustus, I proceeded without delay to the Caledonian Canal early in January; and, after passing through the Crinan Canal in company with Mr. John Gibb, who had met me by desire of the Commissioners, I surveyed the line of the Caledonian Canal with Mr. Gibb and Mr. May, the resident engineer and superintendent of the canal. While upon the survey I wrote two letters to Mr Spearman, to inform him my opinion that no immediate danger of magnitude was to be dreaded from the state of the works at the west end of Loch Lochy, or from the accident at the Fort Augustus Locks, to repair which, in a temporary way, orders were given. These repairs have since been executed, so that the recess wall that gave way is now as secure as the other parts of the lock for the purposes of the present limited traffic. I also requested Mr. May to take such measurements and surveys, as might enable an estimate to be made of the works that appeared to me necessary for the repair or for the completion and improvement of the canal, and to make certain inquiries as to the extent and nature of trade by which the canal, if completed or improved, might be used, to enable me to report more fully to the Lords Commissioners of the Treasury on all the points of your letter.

Since my return from the north, I have been in constant communication with Mr May, who has notwithstanding the extreme severity of the weather, been most diligent and persevering in his surveys. On these being completed, we met in Edinburgh, and went into details of measurements and estimates. It is now my duty to report my opinion on the various points, with estimates, dividing the consideration, as directed by you, into two heads; viz.

"1st. The repair of the lock injured by the late accident, and such further works as may be necessary to avert inundation.

"2d. The improvement of the canal, by rebuilding what may be appetended to be defective in its original construction, altering the depth, procuring tow-vessels, and other measures not urgent, however important."

I shall adhere to this division as closely as I can, premising that the two subjects are so connected and so blended with each other, that it will be very difficult to draw the line between them.

On the 8th February I also received from Mr. Spearman instructions to report such information as I had in my recent survey collected on the subject of the navigation of the Crinan Canal; and, in conversations with that gentleman, I have been requested not to confine my report strictly to the points above stated, but to embrace any information respecting the Caledonian or Crinan Canal which I might be in possession of, and which I might think likely to be useful, when the general question of the canal should come to be considered by their Lordships.

The general history of the Caledonian Canal, with its objects, difficulties and defects, are very ably stated in Mr. May's report of 1st November 1837, addressed to Mr. Smith, secretary to the Commissioners, and in Mr. Smith's letter to the Chancellor of the Exchequer, dated 22d December 1837. These are most important and useful documents, the facts of which I found fully confirmed by my survey. The principal defects there referred to are, however, chiefly in the original scheme and construction of the canal, which have therefore, with the danger attending them, existed from the time of the canal being opened. I name this as a reason against any very sudden alarm; although I fully agree in the necessity for prompt measures of security, in which the canal is certainly defective, probably from the great excess of cost above the estimates, the consequent loss of time, and the difficulty of obtaining funds for the purpose previous to its being opened, all of which are fully stated in Mr. May's report.

SURVEY FIRST DIVISION.

West End Culverts.—Beginning from the west end, the first danger arises from the culverts made between the Bannavie Locks and Gairlochy, a reach of six miles, to carry the mountain floods under the canal into the river Lochy. The masonry of these is certainly very rough, but they are altogether in a better state than I expected from Mr. May's report, the leakage through the work being very small and partial, when, however, the serious effects of a failure in one of these culverts, which would empty the reach of water, is considered, their perfect security, as the locks at present are, is most important.

Gairlochy Lock.—At the head of the reach is Gairlochy Lock, which has the important office of keeping up the waters of Loch Lochy. This lake contains an area of 6,000 acres, the water of which was raised 12 feet above its natural level for the purpose of the canal; in its ordinary state it is 6 to 7 feet, and in times of great floods 10 to 12 feet, above the present level of the canal in the reach below. If at this time any of the culverts were to give way, so as to empty the reach, an addition of 16 feet would be added to the pressure upon the gates of Gairlochy Lock, making a vertical head of 26 to 28 feet, which would, to say the least, place them in danger, and if they should then give way, the contents of the lake, for a depth of 27 feet, would be discharged upon the valley of the Lochy, the general surface of which is much below the level of the canal. The destruction of the canal works, and of property, and perhaps life, would be very great, and therefore the importance of securing the culverts, particularly as the works of the Gairlochy Lock are by no means in the best state. But my decided opinion, in which Mr. May agrees, is, that the renewal ofthe culverts would be but a partial remedy, and that complete security cannot be obtained here but by another lock at the entrance of the lock to the eastward of the present lock. By this means also the trade of the canal, which, with one lock is liable to be entirely stopped by any accident that would prevent the working of any one of the gates, would be secured. As things now are, a ship or steam-vessel coming up to the lock with any way upon her, and striking the gates, might produce this stoppage of the canal for a considerable time, and incur danger, as the dependence must then be upon one pair of gates. Considering all circumstances, I think it fortunate that this has not happened ere this time. I was delayed some time in my passage through the Crinan Canal by a steam-boat having, in the course of the preceding day, run against and seriously damaged one of the gates: a similar accident to one of the Gairlochy gates might have very serious consequences. When at Gairlochy, I advised Mr. May, as a temporary precaution, to stretch a strong chain across the lock at each end; this has to be lowered to enable vessels to pass, but, when drawn up, stops the vessel before she gets to the gates. The estimate of this lock, with the dams and other works, is 15,950*l.* If executed, the culverts in the reach below may, with a little repair, be left in, as the failure of one of them would then be confined to the discharge of the water in the reach of six miles.

Waste Weir for Loch Oich.—A better provision for letting off the flood waters of Loch Oich is the second work required for preventing danger from inundation. In the flood of November 1834, the water rose 7 feet 3 inches above the 20 feet water-mark of the canal, or 15 inches above the gates of Aberchalder Lock at the east end of the lake. An extension of the length of the waste weir, and widening the passage for the waters under it, is all that will be required; and then the present weir can be raised, so as to prevent the waste of water through it in droughts. The expense of this will be 1,287*l.*

Fort Augustus Locks are next in order. The masonry of the five locks is in general very bad, but only the lower lock comes strictly under the present consideration. To repair it, a dam will be requisite against Loch Ness, the sill of the lower lock being 15 to 20 feet under the water of the lake, and then the opportunity should be taken to repair the second lock also. I calculate on taking down to the bottom and rebuilding the recess walls, renewing the segments and other works, which will amount to 7,590*l.*

I think the above are all that come under the head of preventing damage or inundation, without reference to the mere stoppage of the canal, which would be the consequence of a failure at any of the Fort Augustus Locks, and from which, owing to the defective masonry having strained and injured the gates none of them are by any means secure.

The collected amount of the first division is 24,827*l.*

In the above, and in all that follows, I have calculated upon the available and standard depth of water being only 17 feet, which is less by 3 feet than the original design. To obtain 20 feet would be a work of enormous magnitude, difficulties and expense, and would much increase danger, without by any means a compensating advantage. A laden vessel of 38 feet beam (the available width of the locks) does not draw more than 18 feet, and 17 feet is sufficient depth for a ship of 400 to 500 tons,* and few, if any ships in the Baltic or American trade exceed this size.

SECOND DIVISION.

Finishing Canal and remedying Defects.—With the expenditure of 24,827*l.*, for averting inundation, and for the repair of Fort Augustus Lock, the canal will still be left in a very unfinished state, liable to stoppages, inconvenient for business, portions very leaky, and many of its works much out of repair. All these, however, come more properly under the second head, of "finishing the canal, and remedying what is defective in the original construction," which come now to be considered. These, though not urgent as respects security to the country, are most of them essential if the canal is to be kept open, and to prevent still greater expense, which will be the effect if the repairs be delayed. With the present disadvantages, imperfections and want of convenience, it is rather to be wondered that there should have been even the trade there has been; and the fact of there having been even a small trade, certainly goes to prove what there would be if the canal were finished, and convenience given.

In explaining the particulars of the works required, it is so very difficult to separate repairing and finishing from improvements, that the better way may be to state the articles in detail, as I have taken them, with the estimate of each: this will also afford information as to what is the nature and extent of the repairs, and what appear to me to be required in the way of improvements, to render the Caledonian Canal complete and convenient for as great a trade as can be carried on upon it.

The repairs, improvements and machinery as detailed,† amount to 104,490*l.*, and with this expenditure I consider that the canal will be complete and proper for work as originally proposed, and combining additional safety, but with the difference of 17 feet in lieu of 20 feet depth.

Steam Tugs.—As yet I have included nothing for steam-tugs, which, although no part of the original plan, appear to me quite indispensable for the proper working of the canal, as respects either the accommodation to trade, or the probable chance of a return for the great expense incurred in its construction.

PRESENT DIFFICULTIES.

Lakes.—One of the temptations to make a canal at all, and particularly of this great size, from Loch Eil to the Beauly Frith, was the apparent facility afforded by the three lakes, which lie in almost a continuous line, and are for the most part of ample width and depth; viz., Loch Lochy, 10 miles; Loch Oich, 4 miles; and Loch Ness, 23½ miles; together 37½ miles; thus leaving of the whole length of 60½ miles only 23 miles of canal to make. That the cost of making the canal has been much reduced, probably more than half, by the lakes, cannot be doubted; but it is equally apparent, as fully stated in Messrs. May and Smith's reports, that they are now great hindrances to the passage of vessels. From lying in the trough or hollow between two ranges of mountains, the wind blows always parallel to the line of the canal, so as necessarily to be a foul wind in one direction. From the rocky nature of the banks, and their crooked irregular shape, tracking through the lakes is impossible. The width of Loch Lochy and Loch Ness is sufficient for vessels of about 100 tons to work when once fairly in the lakes, but there is a great difficulty in warping against a strong head wind to reach this, and great danger also from the rocky shores in case of a vessel missing stays. Therefore, working or tacking through the lakes is seldom attempted, and the consequence is, that the passage of 60 miles, which, were tracking practicable for the whole length, might be accomplished generally in three to four days, often takes as many weeks; even a month is not unusual, and cases of five weeks have been known. The evil is increased by the westerly winds which prevail for eight or nine months of the year, and are opposed to the direction of what ought to be the greatest trade on the canal. To prevent passage of vessels proceeding from the east to the west end, which the is delay, sometimes three or four months, of going through the Pentland Frith and round Cape Wrath during the westerly winds, was one of the principal objects of the canal, which is thus in a great measure defeated. When I was upon my survey, several vessels were waiting for a change of wind at the east end of Loch Oich, and another number at the east end of Loch Ness, none of them above 135 tons burthen. A very few hours of a steam-tug would have set the whole at liberty. The approaches to the canal from the estuaries at each end are subject to the same inconvenience.

The want of Depth in the canal and portions of the locks is another great

* The late alteration in the measuring for register has tended to reduce the depth of British ships built since the passing of the Register Act.

† The report contains a detailed estimate, which we have here omitted, in consequence of the great length of the report, but we will endeavour to give it in the next Journal.—EDITOR.

drawback upon the use of the canal. This arises partly from the excavation of the canal never having been completed, partly from the weirs at the ends of the locks not being sufficient to support the depth of water, and partly from the great leakage in parts of the canal. Mr. May states that 11 feet in the navigable parts of Loch Oich, and 12 feet in portions of the canal connected with Loch Ness and Loch Lochy, is the depth after a continued drought. Last winter was an extreme case, and as the canal was shut up by the ice, there was no practical evil from the above cause. The water in Loch Oich on that occasion sunk to 5 feet, and Loch Ness to 11 feet, which evidently shows the want of a weir to support the water. I have already named that the reach above Muirtown Locks requires the discharge of 10 sluices, which is 24,000 cubic feet per minute, to supply the leakage of the banks: so great a leakage is perhaps unknown in any other canal navigation; it forms no mean river of itself as it flows by the side of the river Ness, claiming an equality even in ordinary times, and in short water time the leakage much exceeds the river. The sinking of Loch Ness lessens the supply for this leakage, and the canal sinks in consequence. This diminution of depth is objectionable, also by bringing the ships in contact with the rough banks, and injuring the sides, particularly of large vessels, if coppered.

Notwithstanding all these disadvantages, Mr. May states that the delay in going round the northern coast is sometimes such, that there have been cases of vessels having come south and gone through the canal after trying for weeks in vain to make the roundabout passage. This, however, and that there is any trade in the canal, is proof, not of the canal being good or convenient, which certainly it is not, but that the other passages, the shortest of which is 200 miles longer than the canal, are from their length, and the dangerous navigation, most desirable to be avoided; and the fair inference from this alone is, that if the canal were in a good working state, a much greater proportion of the trade between the two sides of the island and Ireland would use it.

Trade upon Canal.—The average of tonnage passing through the canal, exclusive of steam-boats and local traffic, has been about 25,000 tons per annum, without much increase or diminution, during the last ten years: its increase has been checked by various unseasonable interruptions during that period, caused by the imperfect and unfinished condition of the works, similar to what recently occurred at Fort Augustus.

From the accounts collected by Mr. May of the trade of several ports it would appear that the present traffic on the canal is not probably 2½ per cent. of the whole trade going through the Pentland Frith; and, from what has been seen, the canal is not capable, in its present state, of receiving vessels of any considerable tonnage, which, indeed, never attempt it. During the last seven years, only one vessel of 240 tons has made the passage.

Revenue.—The gross receipts of the canal have not exceeded £2,500 since the rates were reduced from a halfpenny to a farthing per ton per mile; the expense of repairs, working, and superintendence, have exceeded £3,000, an amount which is considerable for the trade done; but it is to be observed, that the expense is increased by the bad repair and unfinished state of the works, that the canal works are made for a trade of much larger vessels, and that the expense of them is almost the same as if such vessels, to ten times the present number, were to pass. If the works were finished and put into good repair the expense would undoubtedly be lessened.

If, therefore, the canal is to be kept open at all, I think there is no doubt as to the propriety and policy of doing the repairs and finishing, which it has been seen amount to £129,317, great as this sum is; and I have as little doubt that the effect would be very much to increase the trade, probably beyond what at present there is an idea of.

Steam Tugs.—After all the finishing and repairs are done, still the heavy disadvantage of the lakes will remain, and vessels must wait, as now, for a perfect calm or a fair wind. Indeed, the larger the vessel, the more this objection operates, and the only complete remedy for it, as respects either the accommodation to trade, or the probability of a return for the great expense incurred in the construction of the Canal, is the using of steam-tugs; so much so, that did we not know of the Canal having been projected, and even begun, before steam navigation was introduced, it would be difficult to suppose that steam tracking was not in contemplation, so defective and imperfect is the Canal without it, owing to the lakes, which are, on the contrary, great advantages with it. To make the establishment proper, I think three steam-vessels should be calculated on for the Canal, viz., one for Loch Lochy of 40 horses power, for Loch Oich of 40 horses power, and one for Loch Ness of 50 horses power. Two of these might be sufficient, but not so well as three; and in case of one of them being out of repair, the third would be useful to take its place. The expense of these, with coal-sheds upon the Canal, may be taken at 7,200*l.*; the expense of supporting and working them, supposing they are kept pretty fully at work, Mr. May estimates (from the experience of which he has furnished me with the details) at 1,000*l.* each per annum, which would be a very large addition to the ordinary current expenditure. To do full justice to the navigation, and add to the certainty of despatch, there ought also to be a steamer in the Murray Frith, to bring vessels from Fort George to the eastern entrance, and from Corran Ferry, or even the Sound of Mull, to the western entrance. This would require an additional capital of 6,000*l.*, and incur an addition of 2,000*l.* to the annual outlay, but the accommodation would be most complete.

Gross Amount.—The amount for steam tug-boats, with 10 per cent. for contingencies, added to the repairs and improvements before stated, make a gross amount of 143,837*l.*, or in round numbers 150,000*l.*, for putting the Canal in complete repair, making it proper for all vessels of 38 feet beam and 17 feet draught, providing machinery and utensils, and also a complete establishment of steam-tugs. Probably a less number of steam-tugs might do for a trial, and would be extremely useful; but I have thought better, in this as in the other items, to take what I consider a full amount. With these improvements and additions, the passage from Fort George to the Sound of Mull might generally be depended on to be made within four days, and certainly, even in foul weather, within a week.

Discontinuing Canal Passage.—And now the question presents itself, what, under present circumstances, is best to be done? Ought the navigation of the Canal to be discontinued? If so, this might be done either by keeping up the works, or destroying them. The former would require nearly the same establishment for preservation, and watching for the security of the country, as with the trade; part of the repair I have calculated on must be done, and an annual repair afterwards would be indispensable, all without any income. The other plan, viz., the permanently stopping up or destroying of the works, would require dams and outlets to be made, permanent bridges to be built, the locks filled up or fenced, other works done, and compensations to be made, which it is extremely difficult to calculate, and which, as Mr. May states, might equal in amount the expense of a proper repair, to say nothing of the public inconvenience and the breach of faith which such a proceeding might involve. Might, then, the works necessary to prevent inundation and the minor repairs be done, but the Canal left in its present unfinished and imperfect state, with its present inconveniences? This would, in fact, be continuing the system which has existed since the Canal was opened, but which could not be continued much longer; and, as the works are yearly becoming worse, some general repair must at once be done. The want of funds having probably obliged the Commissioners to expend as little as possible, the defects have been allowed to increase, and, in the course of a short time, it would be found that to have faced the repairs and done them properly would have been a cheaper plan. Certainly there would be no absolute necessity as respects security for adding to the present depth, or for other improvements; but on referring to the detail I have given, I find that only about half of the whole sum (exclusive of the steam-tugs) can be placed to the head of improvements; and I am opinion that, as respects the convenience of trade, or even strictly as a question of expenditure and revenue, the finishings are worth doing along with the repairs; and both, be it observed, can be done cheaper at one time, when the water is out of parts of the Canal than piecemeal. Here I take the opportunity to state that, to do the work effectually, or near the estimate, a season would be necessary for preparation, making plans, entering into contracts, and getting castings and materials to the ground through the Canal, so as to bring the necessary period of interruption to the navigation within the shortest practicable limits.

SUCCESS OF CANAL.

General Opinion.—The original objects for making the Canal are well known. Some of them, as giving employment to the Highlanders and preventing their emigration, it has effected partially. In improving the value of estates through which it passed, and that district of the country generally, it has, with the excellent roads and inns, proved highly beneficial, particularly since the introduction of steam-packets, which ply regularly twice a week to and from Inverness and Glasgow, through the Canal. As a facility for trade, in preventing the long passage through the Pentland Frith and round Cape Wrath, it has hitherto been a failure. This is not, however, if steam is included in the consideration, to be ascribed to the design, which has never yet had a fair chance, the works being incomplete and imperfect in the way I have stated. If the Canal were completed, even to 17 feet water, and steam-tugs stationed upon it, my decided opinion, from all I have seen and have been able to collect, is, that the Caledonian Canal will prove a most useful and important public work, for the general coasting trade of the Kingdom, and for the trade between the Baltic and the west coast, including the Clyde, Liverpool, Ireland, and for vessels bound to America from the eastern ports of the Kingdom. When it is considered that, in the one case, there may be almost a certainty of the vessel making her passage without danger, and with but little wear or tear, from the Murray Frith to the Sound of Mull, within a week in any state of the weather, unless when the Canal is frozen, in place of the dangerous passage of 300 miles by the Pentland Frith, which varies in time from a week to three or four months, with an insurance which, if the cargo be of much value, would alone do much more than pay the Canal rates, and with the expense of lights, there can, I think, be little doubt of the fact being as I have stated. Taking the present rate of one farthing per ton per mile the Canal charge upon a vessel of 200 tons is about 13*l.*, which is from two to three days of the wages, provisions, wear and tear, &c., of a vessel of that size; and if the average difference of time between going round the north coast and through the Canal be taken at ten days, as was stated in evidence, and is probably nearly correct, wages and wear would amount to three times the Canal rates, independently of the risk, the detention of the cargo, uncertainty, &c. In some cases, as in sowing-linseed from the Baltic for Ireland, &c., the detention is so great, that the sowing season is entirely lost. I am informed that the losses to the merchant, as well as to the Irish farmer, through want of good seed from this cause, are considerable.

On the subject of insurance I subjoin a letter from Mr. Alderman Pirie, of London; by this, it appears that the difference of insurance between the Canal and the Pentland Frith may be taken at 20s. per cent. on an average. This, upon a ship of 200 tons burthen, the value of which and cargo (which in Mr. Pirie's opinion may be taken at 6,500*l.*) makes the saving of insurance alone on such a ship and cargo 65*l.*

A letter from Messrs. James Miller and Son, Leith, to Mr. May, on the same subject, is also annexed; by this, the return of premium on going through the Canal is stated at about half the above only.

The lights form another item of difference, but less considerable. A ship passing through the Pentland Frith has to pay the following lights; viz. Pentland Skerries, Dunnet Head, Cape Wrath, Island Glass, Burra Head, and Skerryvore; each one halfpenny per ton, if British, or 1d. per ton if foreign. By passing through the Canal there will be only two lights to pay, viz. Tarbet Ness and Lismore; being a saving of 2d. per ton, if British, and 4d. Taton, if foreign.

In case of war, and the English Channel being infested by steam privateers, the canal will afford a passage of comparative safety for the trade between the West Indies or America, and the east coast of Great Britain.

I have not said that the Caledonian Canal is, as a money account, ever to be a profitable concern, but that it will be a useful public work; that being made, there appears to me no alternative but to finish it; and (this granted) but to finish it properly will be, even as a money account, the proper course to adopt. The time, however, may come, and may not be very distant, when, even as a money speculation, it will appear in a very different light from the present; this partly from the increase in the quantity of tonnage, and partly from the rate. The act allows 2d. per ton per mile, the present charge is a farthing; to raise it without affording increased facilities, would reduce the trade, but with better accommodation; the facts I have stated would justify an addition to the rate.

The Forth and Clyde Canal is a parallel canal, and in some degree a parallel case, although comparatively small, the locks being only 20 feet wide, with a depth of eight feet; it is therefore suited only for small craft under 100 tons. This canal was opened in 1777, and was at work for 30 years before it paid any interest. The tolls are charged not upon the tonnage of the vessels, but at various rates upon goods. On referring to the table of tolls, I find that by far the greatest number of articles is charged 2d. per ton per mile, which is the highest rate allowed by the Caledonian Canal Act, or eight times the present rate charged upon the latter. The trade and profits of the Forth and Clyde Canal are now such that the shares which were originally £100, exclusive of accumulated interest, are now £600 in the market. The accumulated interest upon the original share of £100, taken, I suppose, at compound interest, amounts to four times the original sum, but still shews the canal to be a profitable investment.

Mr. May has, at my request, prepared a table of the tonnage to and from the eastern ports, to show the extent of trade, a portion of which he considers would be likely to use the canal; it is so great, that a small portion of it would make the concern not only useful, but profitable. I dislike the appearing to calculate profits, which is not my department, and ought always to be received with caution, as a basis for any calculation. I would only remark, that, at a halfpenny per ton, the rates upon 100 tons would amount to £12 10s.; and that 400 tons passing daily would produce a gross income of £18,000 per annum, without any material increase of the present outgoings, but rather the contrary, if the works be put in repair.

The limit to the number of vessels passing is caused by the eight continuous locks at Bannavie, near the west end of the canal, through the whole of which, owing to their being no chamber or passing-place, a vessel must pass up or down before another can enter in the opposite direction. This is a great delay and evil; its effects might partly be remedied by dividing the trade, the ascending vessels one part of the day, the descending vessels the other part. A more effectual, but more expensive remedy, as respects money and water, would be making a siding or passing-place in the middle of the chain of locks. As, however, with its present imperfections, the locks can pass more than four times the trade I have named, 400 tons per day, I have not included in the estimate any thing for an alteration in these locks.

Mr. Gladstone, whose long and extensive mercantile concerns and general knowledge are well known, having applied to Mr. May to know if his vessel of 250 tons, bound for Liverpool, could be passed through the canal, was referred to me by Mr. May. After a conference at his desire, I requested Mr. Gladstone to favour me with his opinion, which he has kindly done. His letter has given me no reason to change the favourable opinion I certainly have of what this canal is likely to be at a future period. It has never yet had a chance, and I consider that all its bearings and prospects are completely altered by the introduction of steam; so that the evidence given previous to its formation, and much less its working, since it was opened, has but little to do with the present prospect.

[The report concludes with some remarks on the state of the Crinan Canal which we shall give in the next Journal.—EDITOR.]

BLASTING BY THE AID OF GALVANISM.

INTERESTING EXPERIMENTS ON BLASTING AT CRAIGLEITH QUARRY.

(From the Edinburgh Advertiser.)

On Tuesday, 26th of March last, a large party of gentlemen assembled in Craigleith Quarry, to witness some experiments on blasting by means of galvanism, which were made at the request of the Directors of the Highland and Agricultural Society of Scotland by Martyn Roberts, Esq.

It has long been known that the ignition of gunpowder can be very effectually produced by the application of the electric fluid; but Mr. Roberts has succeeded in producing an apparatus for this purpose, which is simple in its structure, very portable, and which, above all, is easily managed. He has also, in the application of this apparatus to blasting rocks, introduced various modifications of its arrangements, and effected great improvements in the mode of charging.

The apparatus consists of a small trough, about a foot in length, and four inches square on the end, and a battery containing ten pairs of plates. Along the battery runs a bar upon which a tin disc slides freely. This disc, when drawn to the end of the bar, touches another disc, and thus completes the connexion between the opposite poles of the battery. To prevent accidents, the sliding disc is kept in the middle of the bar by means of a spring of coiled wire; and it is impossible to put the battery in action although sunk in the trough without shifting the plate along the bar to the opposite end of the trough. The copper wires which convey the electric fluid to the gunpowder are kept separate during their whole course by a sheath of cotton thread, which is wrapped closely round them in the same manner as in the strings of a guitar, or as in the wire which stiffens the rim of a lady's bonnet. At their termination these wires are bent outwards, and their extremities are connected by means of a fine steel wire half an inch long, so as to form a small triangle, like the Greek capital *delta*. This triangular end is inserted into a small tin cartridge, and ignition of the powder contained in the cartridge is produced by the deflagration of the steel wire which connects the ends of the two copper wires. So rapid is the progress of the electric fluid, that it is impossible to measure the interval of time which elapses between the action at the trough and the explosion of the cartridge. The cost of this apparatus is only about fifteen shillings; and the price of the materials required for the solution is such, that a shilling will cover the expense of keeping the trough in a working state for months. The copper wire which, if properly shielded, may last for years, costs about one farthing for each yard. In applying this apparatus to blasting, Mr. Roberts makes the following arrangements:—In regard to the mode of charging, which is perhaps the most important peculiarity of his method, he leaves a space of about one foot, containing atmospheric air, above and below the gunpowder; and thus obtains, over and above the effect of the gunpowder, all the power which the sudden increase of its volume produces; and thus the same effect is obtained from a smaller charge. He also inserts the tin cartridge into the heart of the charge of powder, and as the cartridge explodes at both ends, the gunpowder is much more instantaneously ignited. Lastly, in tamping, no vent-hole is left, as in the common system, by the withdrawing of the needle; but the tamping is pressed closely round the wire which conveys the electric fluid from the trough to the cartridge. When the tamping is completed, the battery is plunged into the trough, which is at the distance of 40 feet from the bore-hole, and may of course be removed as far as may seem desirable, by giving a small increase to the power of the battery if required, which is easily effected by adding a pair of plates. The spring of coiled wire still keeping the tin disc in the middle of the bar, there is no risk of an unexpected explosion, a danger which occasionally happens by the too rapid ignition of a train or fuze in the common method of blasting. Every one having retired, a person stationed at any safe distance, pulls a string, which makes the tin disc pass along the bar, and the instant the connection of the opposite poles of the battery is established, the explosion takes place. We shall briefly detail the chief advantage of this new system of blasting, which we conceive to be as follows:—

1. Freedom from the dangers which always attend blasting is obtained from various causes. In the common system, the fuse or train must be fixed at or very near the bore-hole, long trains being expensive and uncertain in their action; and accidents, from the too rapid burning of the fuze, are unfortunately very common. But in Mr. Roberts' system, the person who pulls the string which puts the battery in action, may be stationed at any convenient distance. In the present system, perhaps the most common source of accident is the withdrawing of the needle; and this is completely avoided in Mr. Roberts' plan. Lastly, there is less chance of failure, and when failure does occur, the bore-hole may be at once, approached without risk of accident, as the moment the string is slackened, the action of the battery ceases.

2. The next advantage is, the great facility which this mode gives for blasting under water. This is one of the most inconvenient, expensive, and uncertain of all engineering operations. It involves much trouble and expense in laying hoses for the train or fuse, which are destroyed every time; and after all, there are, perhaps, three failures out of ten trials. All this is avoided by Mr. Roberts' system, which is as efficient under water as above it, and involves not one farthing of loss under water more than on land.

3. The great advantage of a much more rapid ignition of the gunpowder, which incloses the cartridge on all sides, and receives the action of the flame over the greater part of its surface at the same instant, gives the new system a great superiority. This is a most important element in the effect of the charge, as its full force is thus secured. In the present method, on the other hand, the powder is fired from the top, and when hard rammed frequently burns away in a series of smaller explosions, producing successive shocks, separated, it is true, by imperceptible intervals of time, but yet producing an effect greatly less powerful than they could have done if concentrated in one shock, so as to act simultaneously.

4. There is absolutely no vent-hole in the mode of tamping pursued by Mr. Roberts, which mode cannot be applied to the present system of blasting. This is an important gain, the vent-hole being a decided loss of power, which is well known to gunners, and to counteract which, the Turks are in the habit of covering the touch-hole of their guns with a bag of sand the moment the priming is fired.

5. The advantage of enclosing a column of atmospheric air, as practised by Mr. Roberts, is obvious, for the force exerted during its expansion is added to that of the gunpowder itself. What that expansion may be it is difficult to tell, as we have no good means of ascertaining the increase of temperature which accompanies the explosion of gunpowder: but as the volume of atmospheric air is doubled for every increase of temperature of 480 deg. of Fahrenheit, the force produced by the expansion of the inclosed column of atmospheric air must form an important addition to the effect of the gunpowder.

6. It follows necessarily from what has been said above, that the combined effects of the instantaneous ignition of the gunpowder, the absence of all vent-holes, and the expansion of the enclosed column of atmospheric air must cause a much greater effect than the explosion of the powder alone in the common system can produce, and consequently that a great economy in the article of gunpowder must result. This is a far more important item in the expense of quarrying and rock excavation than is generally imagined by those who are unacquainted with such works. In the excavation for the Philadelphia Water Works, for example, nearly 3000*l*. were expended in gunpowder, and at the rock-cutting for the new approach to Edinburgh, by the Calton Hill, 1000*l*. was spent in this item alone. In granite quarries the powder for a single shot often costs 3*l*. If the method of Mr. Roberts produces a saving of about two-thirds of the quantity of gunpowder required for blasting, as would appear from the experiments which were made on Tuesday, some idea may be formed of the great economy which would follow on the adoption of the new system.

7. The system of Mr. Roberts makes the simultaneous firing of several blasts easily practised: and in many situations where the removal of the men to a place of safety is difficult, this is an important advantage.

The following details of the experiments made on Tuesday, by Mr. Roberts, are chiefly taken from the notes made by Mr. Inverarity, of the Madras Engineers.

No. 1. Bore of the hole, 2½ inches; depth, 3 feet; powder used, 2 lbs.; column of air left in the bore, only 3 inches in height; line of least resistance, 18 inches; the effect was good; the rock was much splintered, and some fragments were thrown into the air.

No. 2. Bore of hole, 2¾ inches; depth of hole, 8 feet; half the usual charge of powder used; column of air left, 2 feet in height; effect enormous; immense mass moved; few fragments thrown into the air; deep rents all round, and large masses loosened.

No. 3. Bore of hole, 2¾ inches; depth 6 feet; two-thirds of the usual charge of powder: column of air left 18 inches in height; few fragments thrown into the air; but large masses loosened.

No. 4. Dimensions of bole, same as the last; charge of powder less than one-half the usual quantity; column of air left, 2 feet in height; effect very good indeed; much rock loosened; no fragments thrown into the air.

No. 5. Bore of hole, 2¾ inches; charge of powder, two-thirds of the common charge; column of air left, two feet in height; effect excellent; about 300 tons of rock supposed to be torn away; much rock loosened, and deep rents observable; no fragments thrown up.

Nos. 6 and 7. No account of bore-hole taken; powder, one quarter of the usual charge; effect of both was good.

No. 8. Experiment under water. In this experiment, 5 lbs. of powder were put into a bladder and sunk to the depth of ten feet under the surface of the water, in a deserted quarry, west of Craigleith. The string was drawn, and the effect was instantaneous; a dull red globe of light, caused by the explosion of the powder under water, was observed, and immediately there followed a considerable shock which was sensibly felt on the margin of the pool, at the distance of about 100 yards from the explosion; a mass of water, about 10 feet in diameter and 2 feet in height, shaped like a flat dome, rose above the surface of the pool, and immediately after it disappeared, the mud and burned powder boiled up from below like a cauldron.

The Directors of the Highland Society in attendance, and all present were highly pleased with the complete success of the experiments.

EXPERIMENTAL SUBTERRANEOUS AND SUBAQUEOUS EXPLOSIONS AT CHATHAM BY THE VOLTAIC BATTERY,

From the Times of April 9, 1839.

For several months past the Royal Engineers at Chatham, under Colonel Pasley, have been trying experiments in firing gunpowder by the voltaic battery, chiefly under water; and, after many vicissitudes of partial success and of failure, they have at last succeeded in bringing this process to as much perfection as it seems capable of—that is, to as much certainty as the former methods of firing mines in dry soil. They have repeatedly fired gunpowder at the distance of 500 feet, with their conducting wires either buried under ground or led entirely under the water, excepting a few feet connected with the battery, which in their subaqueous explosions was in a boat on the Medway, the powder being lodged at the bottom of that river. In their subterraneous explosion they blew up a field-work, and in one of their subaqueous experiments they blew to pieces a vessel representing a wreck, the fragments of which being of fir timber came up to the surface of the Medway immediately after the column of water thrown up by the explosion. On Saturday last they applied their voltaic battery to the blasting of rock under water. Two very large and heavy pieces of hard sandstone were each prepared with a hole three inches in diameter by a borer, after which a charge of three-quarters of a pound of powder was put into each, and the upper part of the hole was tamped by pouring in small fragments of broken stone round a cone fixed over each charge, in a new and ingenious manner, first suggested by Mr. Howe, clerk of the works of the Royal Engineer Establishment, more than five years ago, which does not seem inferior in resistance to the common mode of tamping, but is much safer and far more expeditious. The conducting wires were led from each charge to the battery, which was placed on the gun-wharf, whilst the stones thus prepared and loaded were lowered down from a crane to the bottom of the river opposite, where the water was fourteen feet deep at the time. The first stone, being of a compact form, was blown to pieces, and the rope sling by which it had been lowered, and which had not been removed, was broken. The second stone, being of a more irregular shape, and much thinner, so that there was not sufficient resistance above and below the charge, was brought up by the crane after the explosion, which had only blown out the solid part of the stone below the bottom of the hole, apparently without injuring any other part of it. Another charge was therefore placed in the same hole, which was tamped both above and below in the mode before described, and the stone was then again let down to the bottom of the river, and after firing this second charge, on being hauled up by the crane it was found to have been broken into three parts, one of which did not reach the surface, whilst the other two, being still held together by the slings, after being raised nearly to the level of the wharf, separated from each other, and fell to the bottom. One of these charges was contained in a tin cylinder fitted to the size of the hole, the two others in canvass bags of the same form covered with waterproof composition. These last experiments, which like several of the former, were witnessed by a great number of spectators, chiefly military, have proved that the voltaic battery may succeed for blasting rock under water, as well as for blowing wrecks to pieces, and in the former supposition the holes in the rock would be formed and the charges placed by means of the diving-bell.

The results of this course of experiments may be of great importance, especially for defensive military mines, because the voltaic battery affords the only possible means of firing several such mines, not only instantaneously but simultaneously, and at the very moment when an enemy's column advancing to the assault is over the spot where these mines have been prepared; whereas by the common mode of firing military mines, by a piece of portfire or slow match connected to a powder hose, there can be no certainty of their taking effect at the precise moment required, so that the enemy's troops might either have passed over, or not yet reached the spot, at the period of explosion: and the simultaneous explosions of conjunct mines by this method is out of the question, for no two pieces of portfire or powder hoses, though cut to the same length, were ever known to burn exactly alike. For subaqueous explosions the superiority of the voltaic battery is still more striking—so much so, that Colonel Pasley has repeatedly declared, that if he had been possessed of the same voltaic apparatus, and had known how to use it last year in his operations in the Thames, it would have saved a great deal of trouble and expense.

Nothing can appear easier than to fire gunpowder under water by the voltaic battery, as exhibited in a lecture-room or scientific institution, but the mode usually adopted on such occasions, of passing the conducting wires into the charge through a cork coated with sealing-wax, and of insulating the remaining length of each wire by enclosing it in small India-rubber tubes, is inadequate and inexpedient, for practical purposes in a rapid tideway and in deep water. In Colonel Pasley's experiments at Chatham, corks and sealing-wax were rejected, the former as being too weak, the latter from being liable to crack, and India-rubber or caoutchouc was also rejected, as being far too expensive; instead of which a composition of pitch, softened by beeswax or tallow, was adopted, the remarkable efficiency of which was proved by keeping one of those experimental charges ten days under water before it was fired, when the powder was still perfectly dry. Each pair of conducting wires used in these experiments was always attached to a rope or line, previously saturated with boiling tar, to prevent it from tearing asunder the soldered joints of the wires, by its alternate contraction and expansion when wet and dry, an effect which on one occasion actually took place before the rope was so saturated. The two wires and rope were bound together by tape and served round with hemp yarn, and in this state they had the appearance of a single rope capable of being coiled and veered out conveniently. One of the most important points necessary was to prevent all strain acting upon the conducting wires from without, and thereby breaking the very small delicate platinum wire within the charge, which, by interrupting the circuit, would render explosion impossible. To guard against this cause of failure in the shocks to which the conducting wires may be exposed in a rapid tideway appeared at first a very difficult task.

The voltaic battery used was of Professor Daniell's improved construction, which, from retaining its energy much longer than any former voltaic battery, he has named the constant voltaic battery, and which Colonel Pasley found to be much superior to the best of the former constructions, at least for the peculiar purpose of firing gunpowder, either under ground or under water. Sergeant-Major Jones, and the non-commissioned officers and privates who have been employed in these experiments, are now as expert in the use of this battery as can be desired, and, being artificers, they are able to make as well as to use such batteries.

Having described these recent interesting experiments of the engineers at Chatham, we may add a brief historical notice of what has been done before. No doubt small charges of gunpowder must have been fired by the voltaic battery, as a matter of experiment and of curiosity, almost as soon as the first rude battery of that description was invented, but the merit of having first applied it to practical purposes is due to Dr. Hare, of Philadelphia, whose proceedings were published some years ago in Silliman's *American Journal of Science* (vol. XXI. page 139), and more recently in a paper communicated to the British Association in 1836, and published in vol. v., in the transactions for the sections of that year, page 45. Dr. Hare states that he used it in blasting rock for the purposes of building, and that he has even fired twelve blasts simultaneously at the distance of 150 feet, by a powerful voltaic battery of a very ingenious and peculiar construction, which he calls a *calorimotor*. He says that the same process might be applied for blasting under water, but he does not mention that he had ever done so himself. Colonel Pasley, after comparing Dr. Hare's mode of firing charges simultaneously, with other modes which he also tried, considers the Doctor's method of soldering the wires together in two parcels, one to be led to one pole, and the other to the other pole, of the voltaic battery, to be the best, and not likely to be improved upon; but he has not adopted any of the Doctor's other arrangements, as they are not applicable to subaqueous explosions under difficult circumstances, and he neither uses the large nor the small iron wires, nor the fulminating powder recommended by Dr. Hare. His own experiments for firing several charges simultaneously have as yet only succeeded at very short distances, because he had not a sufficient quantity of thick copper wire in his possession; and therefore was obliged to employ common bell-wires, only 1-16th of an inch in diameter, which are comparatively useless, the best conducting wires being those of 1-5th of an inch in diameter, which should always be used for great explosions, and none less than 1-8th of an inch even for small explosions or for blasting. The officers who witnessed the various experiments at Chatham are therefore of opinion that it would be absolutely impracticable to fire gunpowder under water at the distance of 300 or 400 yards by six of Professor Daniell's cells, with conducting wires only about as thick as a common bell wire, as was asserted in a paper on the subject of blasting rocks by galvanism, published in a scientific journal for the month of May, 1838; instead of which, they think that to produce ignition by such wires at the last-named distance would require the operator to go to the enormous expense of providing himself with a most unwieldy battery of far greater power than has ever yet been used within the memory of man; for in their own experiments they never succeeded in firing a subaqueous charge, even at the distance of 100 feet, by fewer than eight cells, with common bell-wires: whereas, in using the large wires, the same number of cells was found capable of producing ignition at five times that distance.

We shall conclude by mentioning with due applause the extraordinary success of Mr. William Snow Harris, of Devonport, who did wonders in firing gunpowder by wires led through water at a great distance by the common electrical machine in 1823. But for a detailed account of the interesting experiments of this justly celebrated electrician, which astonished a number of distinguished naval officers and other spectators at Devenport, at the period alluded to, we must refer to the *British Press* newspaper of the 17th of March of that year. Notwithstanding this brilliant success, the voltaic battery must be considered preferable to the electrical machine, because the latter requires a much longer apprenticeship to use it properly; and one cannot expect such skilful manipulation as Mr. Harris has displayed either from military or from civil miners; besides which, that gentleman worked from a warm dry cabin, which is indispensable to the success of the electrical machine; whereas in the experiments of the engineers at Chatham the charges were always fired from Daniell's voltaic battery in the open air, often when exposed to heavy rains, and on one occasion during a very violent snow storm.

EARLY GREEK SCULPTURE.

AT THE BRITISH MUSEUM.

(*From the Times.*)

The casts from the Ægina marbles, of which some time since we gave a full description, have within these few days been placed on the pediment which has been erected for them; it is in that part of the gallery of antiquities called the Phigalian room, and is an exact representation of that portion of the temple of Jupiter Panhellenius, in the island of Ægina, in the ruins of which the statues were discovered. The composition is of brick stuccoed. Although a great improvement on the former shelf, as being deeper and bolder in the relief, and also as having the ornamented figures placed on the apex, yet it is much to be regretted that the situation has not been more happily chosen—first, because it is not erected at a sufficient height from the pavement to give the full effect to the statues, and also, as the width of the apartment does not afford sufficient space for the angles to be carried out, they are necessarily cut off, which gives the whole an unfinished and uncouth appearance. Neither, from the locality, can the spectator take that distant view which is required to bring out the beauty of the whole. Both in the Vatican and in the gallery of Florence a great effect is given to the master-pieces of antiquity by assimilating the edifices in which they are contained with the works exhibited, and avoiding as much as possible the warehouse look which a number of statues of all sorts, sizes, conditions, qualities, placed in juxtaposition must always, in a certain degree, give to the building, which reduces the effect on the beholder, as it prevents the merits and beauties of the sculptures being observed, creates confusion in his mind, who, if he afterwards sees a cast of any single one, is surprised that he has overlooked or forgotten it. The statue of the Apollo in the Vatican, and the Venus de Medicis in the Ducal gallery at Florence, would lose half their grandeur were they republicanised amidst the heterogenous denizens of the spacious halls of the British Museum. The truth of this may easily be proved: let any one observe the superb statue of the Venus found in the baths of Claudius at Ostia through the entrance of the terra-cotta room, and he cannot fail to be struck with its beauty; but he will find on entering that other sculptures placed around, of different character and dimensions, materially reduce the effect. We are well aware that it would not be possible so to arrange that every sculpture of consequence should possess its distinct apartment; but here the contrary practice has been carried to excess. It is strange that as one of the principal defects of the National Gallery consists in the diminutive proportions of its rooms, so that paintings which require both light and space to be viewed with advantage are deprived of both, that in the statue galleries of the British Museum nothing but spacious halls are to be found, and that there is not one chamber so constructed as to bear resemblance in its proportions and its "dim religious light," its "solitude of silence," to those sanctuaries in which many of the statues exhibited were originally placed. We mention this, because there are situations in the Museum where, at least with regard to those Ægina figures, this object might have been effected. In the great centre saloon it would have been easy to have made the partition columns harmonise with the pediment, by which it would have been placed at a sufficient elevation from the pavement; or in the new building which is to occupy the ground the twelfth room now covers and about to be rebuilt. Of the whole collection within the walls these statues are alone as a group *per se* perfect, and had they been placed to advantage would have giren to the general visitor a far better idea of the grandeur and beauty of ancient art than the headless, armless, and legless remains contained in the Elgin saloon. We protest, also, against the unseemly impalement of the horses, which creates a feeling of horror in the mind, and which might easily have been obviated by attaching them to the walls with iron rods invisible to the spectators; also the wall within the pediment forming the back ground should have been made to resemble stone, and not have had the glaring colour it now possesses. On the opposite side of the apartment a similar building is preparing, in which are to be placed the nine figures that ornamented the eastern front of the same Temple of Jupiter whence these were taken.

Within a temporary building opening from the fifth room are the casts from the marble metopes of the great temple of Jupiter Olympius, at Selinus, in Sicily. Valuable as they are, as belonging to a school of art prior to that of Ægina, and probably of a date coeval with the earliest Egyptian, a short notice of them may not be unacceptable, as no account of them is to be found in the synopsis, and to the public in general, although subjects of great curiosity and inquiry, the legend which they tell, and their appearance are altogether as unaccountable as mysterious. At Selinus, in Sicily, there are the remains of six temples of the earliest Doric, within a short distance of each other, and it was during the researches into the ruins of the largest, called the western, and the one furthest from it, named the eastern, by Messrs. Harris and Angell, in 1832, that these ancient sculptures were found: among them there were no single and perfect statues as in the temple at Ægina, which probably arose from the neighbourhood being well peopled, and they had no doubt been repeatedly ransacked. These temples may be reckoned among the largest of antiquity, being equal in their dimensions to those at Agrigentum, in the fluting of whose columns there is sufficient space for a man to stand. Immediately after the discovery, application was made to the Neapolitan Government to allow them to be shipped for England, but permission was refused, and they are now in the Royal Gallery at Palermo; casts were allowed to be taken, and they are these we now describe. They are probably of as early a date as any that have reached our times, and are of different styles of art; those which belonged to the Temple called eastern, whence the sculpture of the head of the dying warrior, and the chariot drawn by horses, were taken, possess much of the Æginitan character; those of the western are of a ruder age, in most of the figures the anatomy resembles that of the earliest coins, but different in many respects from the Greek sculptures; and there is a short and full character in the faces approaching the Egyptian. From the short proportions, the fleshy part of the thigh overcharged, and the peculiar manner in which the hair is arranged, they might be taken for specimens of Æginitan art; but on a close inspection it will be found, that they are the work of artists educated on different principles. At a much later period it is known that the artists of Ægina were employed by the kings of Sicily, and these therefore are not unlikely to have been the work of Carthaginian sculptors brought to decorate a city in alliance and newly founded, which will account for the Egyptian character given to the whole. The cast, which consists of the body and head of a dying soldier, a part of a female figure behind, formed the third metope of the eastern temple, and is a most valuable and curious fragment, and determines the style and character of the sculpture of the temple. It bears a marked resemblance to some of the heads in the Ægina marbles, but it has much more expression; the artist has evidently intended to mark the agonies of death, by the closed eyes, the mouth slightly opened, and the tongue appearing between the teeth; the hair and beard are most carefully and symmetrically arranged and most elaborately finished, the helmet is thrown back, and is of the kind called "*γεῖσον*," part of the crest "λοφος" is visible under the left shoulder of the figure. The fragment of the female is very spirited, and evidently in strong action. These metopes, like those of the Parthenon, are in high relief, and in some parts detached. Thorwalsden has pronounced them equal in execution to the Ægina.

The next, which consists of three figures, one of which has a horse under the arm, is particularly interesting, from the illustration it presents of the death of the Gorgon Medusa. Perseus, emboldened by the presence of Minerva, is represented in the act of slaying Medusa; his eyes are averted from the object of his honour, while his right arm, guided by the goddess, thrusts his sword into the throat of the monster. Pegasus, a winged foul, springs from her blood, and Medusa presses him to her side with apparent solicitude. The monstrous face of the Gorgon is finely represented; the large round head and hideous face rise from the shoulders without the intervention of a neck; all the features are frightfully distorted, the nose is flat and spreading, and the mouth is nearly the whole width of the face, and is armed on each side with two immense tusks; the hair over the forehead is curiously shown, and almost appears to have represented the serpent's, to which it was changed. The figure of Minerva on the right is draped with the "πεπλον" and has the Mæander ornament on the edge. The figure of Perseus is in the centre;

he is armed with the harp of Mercury and the helmet of Pluto, which latter has a pendant falling on each side; the "ωτηνα πεδιλα," or *talaria*, are represented as covering the feet entirely, and bear some resemblance to the ancient greaves; the front part is attached to the ancle by thongs. The form of the young Pegasus is exceedingly beautiful; he seems bounding from the earth. The metope containing the figure bearing two others on its shoulders represents the adventure of Hercules, surnamed Melampyges, from the black and hairy appearance of his loins; the story is as follows:—Passalus and Achemon, two brothers, reviled their mother, who warned them to beware of a man whose loins were covered with black hair; they attempted to rob Hercules while asleep, and from that had the name of Cercopes; in the attempt they failed and awoke him, and he bound them hand and foot to his bow, with their heads downwards, and carried them in that manner; they began laughing on the accomplishment of their mother's prophecy; Hercules asked them why they laughed, and on their telling him the reason, he also laughed and liberated them. The figure of the god is represented as strong and muscular, and the two prisoners have a very ludicrous appearance; in the reversed position, the hair falls in a curious manner; the whole group has been painted in various colours, and in the countenances much of Egyptian expression is to be observed. The horses which draw the chariot formed part of the centre metope of the Eastern Temple; it is very imperfect, and is supposed to represent the celebration of the race of Pelop s and Ænomaus; they are drawn full of fire and courage, and are finely fore-shortened; they have the cropped ears and manes which are observable in those of the Parthenon.

These sculptures are valuable as specimens of the third period of the art, the earliest of which is probably the Hindoo; the great resemblance both these and the Egyptian bear to that style is remarkable, and gives warrant to suppose that it was the original school. Of Hebrew sculpture there are no remains; the command to form no graven image prevented the art attaining the perfection which it reached in the neighbouring country of Syria, and would seem to account, that within the land of Judea no statue bearing marks of great antiquity has been discovered. The Egyptian, the Etruscan, the Selinuntine, and the Ægina schools, furnished the models for the Grecian; and the careful observer has it in his power within the walls of the Museum, to trace, step by step, the progress of the art, till it attained its meridian splendour in the production of those sculptures, whose dilapidated remains are there preserved, and which the accumulated knowledge, genius, labour, and talent of 2,500 years has never yet been able to surpass.

On the walls of the building containing the sculptures we have described are a splendid collection of architectural models and casts from the antique, which were collected by Sir T. Lawrence, and purchased at his death. In the centre is a model of the shield of Achilles, by Flaxman, taken from the *Iliad*, and justice has been done to the conception of the bard. Under glass cases are some very curious models of Druid quoits; the limits of this notice will not allow us to describe them.

ECONOMY OF FUEL.

BY FREDERICK S. PEPPERCORNE, ESQ.

Perhaps there is no subject of more general importance, both in a scientific and a national point of view, than that which forms the title of this paper, more especially at the present time, when owing to the vast and rapid augmentation of steam-power, whether as applied to mines, manufactures, locomotive or maritime purposes, the consumption of fuel has increased to an almost incredible extent. When to these are added the enormous quantity consumed in the iron-works, besides that which is annually exported to India, the Colonies, and foreign parts, we cannot but contemplate the probability of the exhaustion of our coal-beds (there being no reproduction of coal in this country, since there are no known natural causes in operation to form other beds of it) otherwise than as a national calamity, involving the destruction of a great portion of our manufacturing and commercial prosperity. Nor is the period so very remote when the coal districts, which at present supply the metropolis with fuel, will cease to yield any more. The number and extent of all the principal coal-beds in the north of England have been ascertained, and calculations made, by which it would appear that the supply will be probably exhausted in a period of from 350 to 400 years.

Professor Buckland, in his evidence on this subject, estimates the duration of the coal in these districts, at the present rate of consumption, to be 400 years.

Professor Sedgwick, who is well acquainted with the coal strata of Northumberland and Durham, gave his opinion respecting the duration of the coal of these counties, as follows:—

I am myself convinced, that, with the present increased and increasing demand for coal, 400 years will leave little more than the name of our best coal seams.

And he further adds:—

Our northern coal-field will probably be in the wane before 300 years have elapsed.

Already this event has occurred in the coal-fields of Staffordshire, Warwickshire, and Leicestershire, once amongst the most important in the kingdom, and now nearly exhausted; owing to which cause the manufacture of iron, for which these districts were for a long time celebrated, has been nearly discontinued in those counties, and the chief seat of the iron-trade is now removed to Monmouthshire and Glamorganshire; in which two counties alone there are upwards of 100 blast-furnaces for the smelting of iron at present at work, which may be equal to the production of about 400,000 tons of iron a year. Now it is a known fact, that from five to six tons of coal are required for the production of one ton of iron, consequently 2,400,000 tons of coal would be consumed in South Wales in the iron-works alone.

The quantity of iron made in Great Britain in the year 1836 is stated in the "Mining Journal," of October 7, 1837, to be about one million of tons, in the manufacture of which six millions of tons of coal would be consumed.

The total consumption of coal in Great Britain in the year 1837 was stated to be 22 millions of tons, and the quantity exported to India, the Colonies and foreign parts about two millions of tons. It is probable, however, that even this amount was considerably under the actual quantity consumed; and if we take into consideration the immense increase that has taken place since that period for the purposes of steam-navigation and locomotive engines, we shall probably be considerably under the mark in stating the whole quantity of coal consumed in Great Britain, exclusive of that which is exported at 30,000,000 of tons, to which must be added *one-third* of the whole amount, or 10,000,000 of tons, *for coal left and wasted in the mines.* (See "Holme's Treatise on the Coal Mines," who states the waste of small coal at the pits' mouth to be one-fourth of the whole, and that in the mines one-third.) This enormous proportion of coal left and wasted in the mines seems so incredible as to require some further explanation, and this cannot be better given than in the words of an eminent geologist, Dr. Buckland, in his "Bridgwater Treatise," who says:—

We have for many years witnessed the disgraceful and almost incredible fact that more than a million of chaldrons (1,350,000 tons) per annum, being nearly one-third part of the best coals produced by the mines near Newcastle have been condemned to wanton waste, on a fiery heap, perpetually blazing near the mouth of almost every coal-pit in that district. This destruction originated mainly in certain legislative enactments, providing that coal in London should be sold, and the duty upon it rated, *by measure* and *not by weight*. The smaller coal is broken the greater the space it fills; it became, therefore, the interest of every dealer in coal *to buy it of as large a size and to sell it of as small a size as he was able.* This compelled the proprietors of the coal-mines to send the large coal only to market, and to consign the small coal to destruction.

In the year 1830 the attention of Parliament was called to these evils, and pursuant to the report of a Committee, the duty on coal was repealed, and coal directed to be sold by *weight instead of by measure.* The effect of this change has been that a considerable quantity of coal is now shipped for the London market in the state in which it comes from the pit, that after landing the cargo the small coal is separated by skreening from the rest, and answers as fuel for various ordinary purposes, as well as much of the coal which was sold in London before the alteration of the law.

The destruction of coal on the fiery heaps near Newcastle, although diminished, still goes on however to a frightful extent; that ought not to be permitted, since the inevitable consequence of this practice, if allowed to continue, must be, in no long space of time, to consume all the beds nearest the surface, and readiest of access to the coast, and thus enhance the price of coal in those parts of England which depend on the coal-field of Newcastle for their supply; and, finally, to exhaust this coal-field at a period nearer by at least *one-third*, than that to which it would last, if wisely economised.

The concluding observations of Dr. Buckland, on this important subject, are so much to the purpose, that it will be a sufficient apology for introducing them here. He proceeds thus:—

We are fully aware of the impolicy of needless legislative interference, but a broad line has been drawn by nature between commodities annually or periodically reproduced by the soil on its surface, and that subterranean treasure and sustaining foundation of industry which is laid by nature in strata of mineral coal, whose amount is limited, and which when once exhausted, is gone for ever. As the law most justly interferes to prevent the wanton destruction of life and property it should seem also to be its duty to prevent all needless waste of mineral fuel, since the exhaustion of this fuel would irrecoverably paralyse the industry of millions.

The tenant of the soil may neglect or cultivate his lands, and dispose of his produce as caprice or interest may dictate; the surface of his fields is not consumed, but remains susceptible of tillage by his successor: had he the physical power to annihilate the land, and thereby inflict an irremediable injury upon posterity, the legislature would justly interfere to prevent such destruction of the future resources of the nation.

This highly favoured country has been enriched with mineral treasures in her strata of coal, incomparably more precious than mines of silver or of gold. From these sustaining sources of industry and wealth, let us help ourselves abundantly, and liberally enjoy these precious gifts of the Creator; but let us not abuse them, or by wilful neglect and wanton waste, destroy the foundation of the industry of future generations.

Might not an easy remedy for this evil be found in legislative enactment, that all coals from the ports of Northumberland and Durham, should be shipped in the state in which they come from the pits, and forbid ding, by high penalties, the skreening of any sea-borne coals, before they leave the port at which they are embarked. A law of this kind would at once terminate that ruinous competition among the coal-owners, which has urged them to vie with each other in the wasteful destruction of small coal, in order to increase the profits of the coal merchant, and gratify the preference for large coals on the part of rich consumers; and would also afford the public a supply of coals of every price and quality, which the skreen would enable him to accommodate to the demands of the various classes of the community.

A farther consideration of national policy should prompt us to consider how far the duty of supporting our commercial interests, and of husbanding the resources of posterity, should permit us to allow any extensive exportation of coal, from a densely peopled manufacturing country like our own; a large proportion of whose present wealth is founded on machinery, which can be kept in action only by the produce of our native coal-mines, and whose prosperity can never survive the period of their exhaustion.

At the last meeting of the British Association at Newcastle, Dr. Buckland read a paper on the application of small coal to economical purposes, in which he referred to the well-known enormous annual waste of coal at the mouths of the various pits near Newcastle, and stated that, owing to what he had said on the subject in his Bridgewater Treatise, the attention of a benevolent individual had been called strongly to the subject. That individual had succeeded in agglutinating the small particles of coal into a firm compact mass, by a process at once simple and cheap; and he believed he had taken out a patent for the method. There would be even an economy in using this coal for many purposes, as it occupied *one-third* or *one-fourth* less space, when packed in boxes, than coal in its ordinary state. Specimens were exhibited, which had a firm compact appearance, and Dr. Buckland stated that by the direction of government, trials had been made under the inspection of competent persons, and that success had been complete, the combustion being at least as productive as that of coal in its common state.

The experiments alluded to by Dr. Buckland, took place at Woolwich Dockyard in August last, under the superintendence of Messrs. Kingston and Dinnen, two experienced engineers. The "prepared fuel," as it was termed, is a composition of skreened coal, river-mud and tar, cast into blocks of nearly the size and shape of common bricks. One great advantage attending this form is that a much larger quantity, weight for weight, may be stowed in the hold of a sea-going steam-vessel, than of common-coal, and it is besides not liable to shift its position, like the latter. An Engine was worked with this prepared fuel, and the consumption for 6 hours 45 minutes, was 750 lbs. The same engine required 1165 lbs of north country coals to keep it going for the same time, showing a saving of 415 lbs in favour of the prepared fuel.

At another experiment, Welsh coal was used, and 1046 lbs. were consumed, while 680 lbs. of the prepared fuel easily performed the same work in the same time. It was also remarked that it required about 50 lbs. less of the prepared fuel to get the steam up, than of common coal, and that the steam was maintained by it at a more even temperature, with very little feeding.

It would seem, therefore, that there can no longer be any excuse for a continuance of the wasteful practice of consuming the small coal at the pit's mouth, to say nothing of that which is thrown aside as useless in the pits themselves, and which never sees the light, since by this invention, that which was before considered as mere refuse, has acquired a certain fixed value, and it is to be hoped that this disgraceful practice is now completely put a stop to.

Of the various substances which have been used as a substitute for coal, where that article is scarce, peat stands foremost in the list. Our peat or turf beds are of great extent, especially in Ireland, and contain a valuable reserve of fuel, applicable, when properly prepared, to all the purposes of mining or manufactures. An important feature in this fuel is, that, unlike coal, of which we know of no instance of reproduction, turf or peat is continually being reproduced; in fact, in many parts of England the growth exceeds the consumption, and consequently the turf beds in those places are on the increase.

Before being used, however, this fuel requires to be thoroughly dried by exposure to the sun and air, during which process it contracts considerably in its dimensions, and increases in density, so much so as frequently to approach in hardness and appearance to common coal. This, however, is only the case with bog peat, or that which is saturated with water, but turf may be made so by placing it at first in running water, and then suffering it to dry. Artificial means have been used for compressing peat; and a machine for this purpose, invented by a patriotic nobleman, Lord Willoughby de Eresby, has been attended with complete success. The chief advantage of this invention is the great saving of time effected in the conversion of the wet peat into a solid dry fuel.

In France peat is extensively employed, both for domestic purposes and in the different metallurgic processes, after having been converted into a charcoal by placing the peat to be carbonised in a furnace, where it is ignited, and smothered up in the usual manner. The iron made with this peat charcoal is described to be of a superior quality to Swedish iron, being more malleable, and more easily welded, owing, as it is supposed, to its comparative freedom from sulphur, which is known to exist in large quantities in coal, and which is not completely driven off by its conversion into coke.

Very lately this peat-coke has been introduced into some of the transatlantic steamboats, in combination with a certain proportion of resin. This resin fuel is not used alone, but when about 2½ cwt. of it are mixed with 20 cwt. of coal, a much better combustion of the coal takes place; and the effect is described as being equal to that which would be produced by 27 cwt. of coal. The mode of using it is by throwing it in front of the fire with each charge of fresh coal.

For many years the attention of scientific and practical men has been directed to a method of using a valuable description of coal, the use of which, owing to its peculiar properties, has been, until lately, confined within a very narrow compass.

This fuel is the "anthracite," or stone-coal of South Wales. Its chief properties consist in its freedom from sulphur or bitumen (being composed wholly of carbon, mixed with a slight proportion of oxide of iron, silex, and alumina), its great durability and steady heat, burning clearly without smoke or flame. These valuable qualities have long secured to anthracite a very extensive use in the drying of malt in many districts of England, where it is preferred even to coke or charcoal; but it is only within the last few years that it has acquired the high rank of importance, in a national as well as a domestic point of view, which it now possesses.

Dr. Arnott, for whose stoves it is exclusively recommended by him, has declared that it is a blot in the police regulations of London, that all great manufacturers are not confined to the exclusive use of this description of coal, its non-emission of smoke and noxious vapours, tending so much to preserve the purity of the atmosphere in the metropolis. Since, so long back as the reign of Elizabeth, the burning of coal was prohibited in London during the sitting of Parliament, lest the health of the knights of the shire should suffer during their abode in London (so careful was this queen of the health of her subjects); it is surely incumbent on us in the present day, when from the immense increase of the number of manufactories of every description, the atmosphere of London is never clear from smoke, to pass some legislative enactments to remedy the growing evil. Experiments have satisfactorily proved that anthracite gives out in combustion 30 per cent. more caloric than coke or bituminous coal.

In America, this valuable mineral has been long and extensively employed, not only for manufacturing processes, but also in steam-navigation, and for locomotive engines; also for the warming of apartments, and for every other domestic purpose: indeed, its cheapness, the intensity and durability of the heat which it produces, together with its perfect safety and freedom from smoke or smell, give it a decided preference over every other species of fuel.

Mines of this coal have for some years been extensively worked in Rhode Island, Massachusetts, and other states; but it is in Pensylvania that it is found in the greatest abundance: there the anthracite coal formation covers a tract of country many miles in length and breadth, extending across the two entire counties of Luzerne and Schuylkill. Throughout this region it is obtained with very little labour, being situated in hills from 300 to 600 feet high above the level of the surrounding rivers and canals, and consequently easy of transportation to all parts of the Union. It exists in horizontal beds, from 15 to 40 feet in thickness and covered merely by a few feet of gravelly loam. This coal has been found in several European countries, and exists abundantly in Ireland; but the great supply of anthracite for this country is found in that part of the great coal formation which environs Swansea and Carmarthen Bays, and which forms a part of the great coal-field of South Wales. Here it exists in immense quantities.

It is, however, but very recently that the attention of engineers has been turned to the use of this fuel for locomotive engines: a short time since, a trial of it was made under the sanction of the directors of the Liverpool and Manchester Railway, and the following is the report of the talented engineer of that company:—

In the first instance, the engine ran out with a load about 6 miles, and the coal was found to do very good duty without any difficulty being experienced, either with the tubes, or in the getting up of the fires. The engine brought back a load of coal waggons from the Hetton Colliery, and acquired a speed of 21 miles an hour, thus loaded. Another trial was made in the evening with the same engine for the whole distance to Manchester, taking 5 loaded waggons; the journey was performed in 1 hour and 29 minutes.

The consumption of anthracite was only 5½ cwt: although a large portion was wasted from the fire-bars being too wide apart for the economical use of this fuel. The engine would have used upwards of 7½ cwt. of coke for the same journey, with the same load."

The trial with locomotives, then, must be considered quite conclusive and the next object most deserving the attention of practical men, is the application of anthracite to the marine engines of sea-going steam vessels. When it is considered that 30 per cent. at least is saved in the stowage by this description of fuel, the importance of this subject will be at once made manifest, and there can be little doubt that with certain trifling alterations, in the construction of the boiler and furnace, the object may be attained.

It is not suprising that, considering the importance which has of late years been attached to every means of economising fuel, the attention of scientific and practical men should have been directed to various methods for accomplishing this object, and numerous alterations and improvements have been effected in the furnaces and boilers of steam engines, by which the heat given forth by combustion has been made more available, but much remains yet to be done, as a very large quantity of heat is lost from; the smoke which is wasted, the heat which passes up the chimney, and from the imperfect manner in which coal is generally consumed.

An ingenious invention for intercepting and returning to the boiler-fire a large portion of the heat which would otherwise pass up the chimney and be dissipated, was brought into notice in England a few years ago, by a German named Schauffelen, and was denominated "Schauffelen's Hot-air Furnace Feeder." The invention consists in the use of a number of metal pipes or tubes open at the bottom, but closed at the top. These pipes are placed in a vertical position in the chimney, and the air in passing through them becomes heated from the current of hot air passing up the chimney, and in this state is supplied to the fire, all ingress of cold air being carefully excluded by means of closely fitting iron plates attached to the ash-pit.

With respect to the amount of saving in fuel effected by this apparatus, it is stated by the inventor as varying from 20 to 25 per cent., when in good working order, and its advantages are not entirely confined to a saving of part of the heat which would otherwise escape up the chimney, but moreover a more intense heat in the fire-place is maintained, and consequently a more complete combustion of the fuel and smoke takes place.

Another invention of great simplicity for the economy of fuel, and the prevention of smoke, is described in the *Mining Review* of August 31, 1838. The process consists merely in the introduction into the furnace of steam in small quantities, through a tube taken from the boiler, and discharged over the fuel at any convenient place. The end of the tube should be formed with a fan-shaped termination, perforated with minute apertures, so as to throw the steam in small jets down upon and over the fire. One effect produced is *the absolute prevention of smoke;* another, the operation of the fire is fully doubled, and the steam employed itself consumed. The employment of steam also greatly increases the draft of the chimney.

"It is held by competent authorities, that 1lb of Newcastle coal (supposing the whole of the heat omitted by its combustion was made available), should drive off in steam 14lbs *of water.* This however, is very far beyond what is actually done in practice, by ordinary steam-engine boilers. Indeed it is found by experience to require as much as 1lb of coal to convert into steam 4 to 6lbs of water, 6lb being considered a high product. By means of Mr. Ivison's method however, it is found that an average of 13lbs. of water are evaporated by 1lb. of ordinary Scotch coal, thus more than doubling the results heretofore obtained, and consequently effecting a saving of upwards of 50 *per cent* of fuel."—*Mining Review*, August. 31, 1838.

Our great source of loss of heat and, consequently of fuel, in most large establishments where steam power is extensively employed, arises from the radiation of heat which is constantly taking place from the boiler, where, as is most frequently the case, no means are adopted for preventing it. When we consider the large surface that is exposed by each steam-engine boiler, and that from this there is continually going on a powerful radiation of heat into the surrounding atmosphere, it is evident that the loss from this source alone, must be immense. If, therefore, this large body of heat can, by any means, be intercepted and returned to the boiler, it is clear that there will be a saving of all that fuel which was required to raise that heat in order to disperse it again. The method of doing this is simple, and attended with very little expense. All that is necessary to be done is to surround the boiler with a jacket or casing of wood or brick, leaving a space of a few inches between it and the boiler, to be filled with some substance which is a slow conductor of heat. The material that has been employed for this purpose, is a mixture of sawdust and ashes, rammed in so as to lay close to every part of the boiler; and where this system is carried to its full extent, which is in the large pumping engines, used in the mines in Cornwall, not only the boiler, but also the cylinder and the steam-pipes, are, in the Cornish engines, completely encased with some non-conducting material, which renders the engine and boiler-houses as cool as the interior of a dwelling-house, where there are only ordinary fires,—a sure proof that little or no heat is lost by radiation.

Another proof of the efficacy of this system is, that even after the engine has been standing still for 12 hours, very little heat is lost, and if it is necessary to start it suddenly, as in case of emergency, scarcely any time is lost in raising the steam, and *one fourth* the fuel only is required; whereas in the common engines and boilers, where every vessel containing steam is exposed to the atmosphere, it takes from 20 minutes to half an hour, firing hard, to raise the steam to the requisite pressure.

It would occupy too much time, and swell these remarks to too inconvenient a length, were I to enter into the details of all the inventions that have been proposed for economising fuel, although many of them are of great value, as their general adoption sufficiently testifies; whilst others, either from the complexity of their parts, or their general inapplicability, have soon fallen into disuse. It is hoped, however, that sufficient has been said in this paper, to point out the great importance of the subject, and to show, that however much may have been hitherto done, much yet remains to be done, before we can confidently state that the whole *inherent virtue* residing in one pound weight of coal or other fuel, is made available.

FREDERICK S. PEPPERCORNE.

15, Buckingham-street, Adelphi,
April, 8 1839.

PUBLIC COMPETITIONS.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

Extract from Report of the Committee appointed to consider the subject of Public Competitions for Architectural Designs. Laid before the Special General Meeting, held 24th January, 1839.

THE Committee appointed on the 9th October, 1838, to consider the subject of Public Competitions for Architectural Designs, beg leave to report.

The arguments advanced in favour of competition are sufficiently forcible. Emulation is said to be the soul of excellence in the arts and sciences—the recognised talents of the elder professor are supposed to be maintained in activity and progressive improvement, and his employers to be protected from the *routine* manner, which security in public patronage and private practice are too apt to produce:—while an opportunity is afforded to the young aspirant, to take that place in public estimation to which his talents may entitle him.

The formation of the programme, upon which competitors are required to frame their designs, becomes the first essential point for consideration, and a deficiency on this point is perhaps the most general evil in the present system. The precise objects to be attained, the most desirable means of attaining them, the circumstances that must control the plan with regard to the site and other localities, the sum of money to be expended, and many other particulars of which every case of competition brings its own, are seldom ascertained and settled, so as to lay the groundwork of well-defined instructions upon which competitors may proceed. When the decision is to be made, the judges discover for the first time, that they have been ignorant of their own intentions; their loose and ill-digested instructions are abandoned altogether, and the architect, who has acted with the greatest good faith in adhering to them, is the first to be deprived of his reward. In another view of the case, an architect, who may have suggested a design not reconcileable with the crude, undigested, and perhaps contradictory preconceptions cast into the programme, may virtually exclude himself from the competition, and his employers from the adoption of his ideas.

When we consider architecture as a combination of science and art requiring great experience and taste, together with the important essential in its professors, of character and conduct in the execution of their works—when we consider the variety of attainment necessary for the production of an architectural design, it is not too much to expect some corresponding qualifications, together with deep and patient consideration, on the part of those, who take upon themselves to sit in judgment upon it.

To read a plan is admitted by the most practised to be the result of great experience and knowledge. To pursue the clue through the labyrinth of ichnography, and to follow out arrangement and economy of space, and the combination of convenience and beauty, require not only great intelligence and discrimination, but a long course of analogous study. Even the experienced professor must go through the whole subject minutely. How often does any scruple or doubt of their own competency embarrass a committee appointed to judge of architectural designs? Do they consider any further qualification necessary, when they have assumed to themselves the undefined and flattering attribute of *taste?*

Again, it is well known to experienced architects how difficult it is to form a correct judgment upon designs on different scales and in different styles of drawing—and yet committees do not hesitate to select a design, without suspecting it in the slightest degree, that they may have been captivated by the meretricious allurements of the artist, and that they may have admitted the accessories of pictorial representation to have the weight of argument and reason, particularly when coloured views and scenery, aided perhaps by false perspective, or taken from impossible points of sight, are introduced to the destruction of any common ground of comparison. The delusion is only eventually detected when it is past remedy.

Another evil, which the necessary inexperience of committees, as at present constituted, renders it difficult for them to meet, is, that a design may be selected for its decorative character, which it afterwards proves inexpedient to carry into effect, on account of the expense attending it. In this case it frequently happens, that, in preference to encountering the inconveniences of retracing their proceedings, the committee suffer the design to be stripped of every thing, which originally recommended it to their notice; thus disappointing the expectations of the public, and inflicting a flagrant injustice upon the other competitors.

In proceeding to consider what remedies may be suggested for the evils here enumerated, they will be found to arise naturally out of the statement itself.

It is not to be doubted that the proposers of competitions may prescribe any terms they think fit. Whether, therefore, they prefer laying down precise instructions on every point, or leaving themselves a certain latitude in their decision, or making it entirely open to competitors to offer any suggestions that may occur to them, it rests entirely with the professor to decide for himself, whether the conditions, and the personal character of those who propose them, are satisfactory.

But whatever the conditions may be, they ought to be clear and explicit, that the competitor may know precisely and unequivocally upon what he has to rely. Whenever it may be expedient to lay down definite instructions, they ought to be strictly adhered to, when judgment is to be founded upon them, and every design rejected, which shall be found not to conform to them.

In framing instructions care should be taken to distinguish accurately between the objects to be attained, and the means of attaining them. The former cannot be too accurately ascertained, or too explicitly described; but the latter should be left as much as possible to the architect, for otherwise a proper scope will not be afforded for the exercise of a variety of suggestions, and one great end of competition will be frustrated. If, however, there should be a decided bias in favour of any particular style or mode of composition, it ought to be ascertained and stated in the instructions.

As the formation of definite preliminary instructions, and a decision strictly founded upon them require more experience and knowledge of architecture than miscellaneous committees may be generally supposed to possess, it is suggested that in all cases competent professional advisers should be referred to upon these and other points connected with the duties of the Committee: but without taking the final decision out of the hands of the original parties to the competition, or relieving them from its responsibility.

Professional opinions are especially requisite in regard to practical construction, also to minute arrangements, as of light, ventilation, and warming, in reference for example to prisons, hospitals, and places for public meetings. The maximum amount of the intended expenditure should be given, and when a selection is made, proper means should be employed to ascertain that the cost of executing the design will not exceed the estimate.

In order to assist the judgment by establishing an uniform comparison, the drawings presented for competition should always be made to one scale; and limited to one style of finishing, as in Indian ink, with no colour, unless for such a purpose as that of distinguishing different materials in sections. Perspective drawings, if correctly made, are certainly desirable to show the proper effect of designs; but they should be restricted to specified points of view. Models should be received with caution, as not being unexceptionable tests of the merits of a design.

But they must advocate the principle, that as much publicity as possible should be given to the proceedings in all cases. For although the public at large cannot be accepted as a competent judge upon cases requiring peculiar attention and information, yet the exhibition alone of the drawings, accompanied by the instructions upon which they are founded, cannot fail to render those, to whom judgment is confided, both diligent and scrupulous in the discharge of their duty. To effect this object, however, experience has shown, that the expression of the public opinion must precede, as well as follow, the decision of the judges. The public exhibition of designs, previously to the final decision upon them, might render it expedient to follow generally the practice, now only partially adopted, of concealing the names of competitors under a motto or cypher. On any other ground the practice is scarcely worthy of mention, and is liable to the objection of being deceptive; for your Committee have sufficient evidence to prove, that, though apparently fair, it is absolutely futile in effect.

Although the inquiries, which may be addressed by professional men to the institutors of competitions, must necessarily be dictated by the peculiar circumstances of every case, yet the following, although merely proposed as explanatory of the intentions of the committee, may be found generally applicable.

By whom are the designs to be examined and selected?

Have any designs been laid before the parties previously to the competition being proposed?

Have the parties any architect, or person professing to be an architect, in their employ?

Will any means be adopted to ascertain that the designs can be executed for the sums estimated?

Will the parties undertake to lay aside all designs which cannot be executed for the sum estimated?

Is it the intention of the parties at once to exclude from the competition all designs not in strict conformity with their instructions in every respect?

Will the architect, whose design is selected, be employed to execute the work, provided his character and standing in the profession be such as to render him unexceptionable?

REVIEWS.

Illustrations of Science by Professors of King's College, London; Mechanics. By the Rev. H. Moseley, M. A., F. R. S., Professor of Nat. Philosophy. London: Longman, Orme and Co., 1839.

One of the most convincing arguments perhaps in this commercial country against any single institution for engineering education in this city, or indeed in any other, is the listlessness which results from the want of competition. Competition is one of the grand principles evolved by the investigations of the political economists,—perhaps the truest, and one that influences not only trade, but many other economical pursuits. Lord Brougham, applying this to politics, has, in his recent work on Eminent Statesmen, pointed out the mathematical operation of this law, if we may so term it, by asserting that the result is to produce an action neither of one side nor of another, but compounded of the two, just like the movement of two physical powers. We may leave to others to discuss that question, but perhaps some of our philosophical friends may be able to demonstrate that thus of two wrong courses a right one may be produced. If we consider the working of this competition in other branches of professional education we see at once in what a different position we stand from other countries. At Paris there is the only medical school for all France; and it certainly presents opportunities for ensuring the selection of the highest talent, and concentrating everything in one magnificent establishment. In London there are no less than fourteen complete schools: at Dublin three; besides nearly a score provincial establishments. The effect of this, some would say, would most certainly be to ensure mediocrity, by the employment of so many individuals, while the dispersion of talent would very much enfeeble the whole course of medical education. The operation, on the contrary, is, by the maintenance of an energetic competition, ever to elevate the standard, and ensure the ascendancy of men of talent; and every school is obliged to make the greatest exertions to command pupils, since it is only by securing able professors that they can maintain their standing. It must be remembered, that none of these schools have the privilege of giving licenses to practice, and that the examining body is totally distinct from the instructive. At Paris it is a principle something like this, and totally distinct from the system adopted, which maintains the superiority of that school; for from the turbulence of the pupils, they as speedily put down an obnoxious professor as the incipient surgeons of London; and thus counteract the evils of a stagnant system and government control; although it is not an impossible occurrence for a professor to be absent from his chair a year, or even two. The beauties of a non-competing system were most admirably illustrated in the recent proceedings at Oxford, and bear almost too much the appearance of irony even to be quoted with seriousness. The case was briefly this; Professor Daubeny, and other teachers of the natural sciences—who are the only professors who teach at all, in consequence of the miserable paucity of their auditors, (Daubeny's chemical class being ELEVEN!!) brought forward a law to render attendance on one of the scientific courses imperative on students proceeding to a bachelor's degree of arts, and making in consequence some proformal alterations, increasing the number of lectures of the professors. Upon which proposition, the decision of the learned authorities was, that no compulsory attendance on the courses should be enacted, but that the *proposed regulations as to more frequent lectures should be enacted*; by which solemn farce, an important question was eluded, and well-deserving men were entrapped into unnecessary duties. The zeal of such men as Daubeny, and his colleagues, cannot indeed be too highly commended; when, instead of profiting by the do-nothing example of their brethren, they continue to devote their talents to audiences of *eleven*, in the First University of the World.

To come, however, to the instance presented by the volume before us, we have every reason to congratulate ourselves upon possessing the house divided within itself, instead of that founded upon the rock, or rather pillow. University College came first into the field pledged to the adoption of the most enlightened principles; and King's College was brought in as its opponent; and most nobly has the contest been carried on. University College has been equally unfettered, both as to principles, and as to men, while from its very constitution the other establishment at once imposed upon itself leaden chains ; at best placed in a go-cart, in the way of right, and certainly hampered by many superstitions and absurdities, it was additionally fettered by being obliged to select its professors from those very establishments whose stifling influence was most sought to be evaded. The result, however, even those who hoped most for its success, could never have anticipated; and the conductors of King's College, supporters as they are *ex-officio* of nepotism and patronage, deserve the highest credit for the discrimination and disinterestedness which they have shown in the choice of professors, who by finding out new paths, have emancipated themselves from the trammels in which they had been placed, and secured their own fame and the prosperity of the institution. It is not our desire to elevate the one institution at the expense of the other; and if from deference to the work before us our remarks are restricted to King's College, it must not be considered that we detract from another establishment the labours of whose members have ensured it a high meed of fame.

We cannot better illustrate the justice of the remarks we have made than by referring to the outlines of the courses, which are those proposed to be delivered before the class of Civil Engineering, and they mark a new era, when science is no longer to be conventional, but practical; when it is to leave off its Procrustean propensity of an artificial standard, and to adapt itself as it ought to do to every capacity and every pursuit. Pedantry of all kinds is most disgusting, but the pedantry of science is positively injurious, for it causes a waste of time to the practical man too often irreparable, and it is indeed time that we should get rid of this clog upon our progress. The courses proposed for this year are of course introductory; and all, like those on mathematics and natural philosophy, special : we have occasion afterwards to revert to Professor Moseley, on "Natural Philosophy;" so that we shall at present consider some of the other subjects.

Professor Daniell has arranged his course in a manner totally different from the general run of university lectures, and with an ability which shows his desire of promoting the instruction of his pupils rather than maintaining the dogmata of science, merely filling up the dull routine of official duty. His first year's course contains a preparatory view of the forces which concur to the production of chemical phenomena. An endeavour, says the Professor, will be made to systematize what the beginner already knows from common experience, and to lead him on to increase this knowledge gradually by the results of experiment ; to teach him the inductive method of reasoning from phenomena ; and to explain to him the general views and theories of the science. The display of these forces in the grand operations of nature will form principal objects of illustration, and particularly in the constitution of the atmosphere, the phenomena of thunder and lightning, winds, rain, &c. In the second year it is proposed that the students shall attend a course of practical chemistry, in which the application of the science to the arts will be taught, and the processes of the different manufacturers, of metallurgy, and of domestic economy will be explained and illustrated. This is a method which ought long since to have been adopted, and it is one which promises to rescue the physical sciences from being a mere set of empirical processes, and placing them in the hands of the students as they ought to be—sciences, and not arts. Science is one, but arts are many ; and so long as the student is only taught a series of processes, without being properly grounded in the principles, so long will his progress in science be limited, and he remains a journeyman where he might be a master. There are few sciences indeed, of which many important principles are not sown in the human mind by observation, and it wants but little instruction to bring out these, and systematise the stores of knowledge. Instead of considering the mind of the student as ground entirely to be made, another course should be adopted, and it should be regarded as a soil which possesses many of the elements of fertility, and to which only the complementary addition is necessary to make it productive. Taking, too, nature as a basis, the student is put on the road not only to learn from the experience of the past but to profit from the events of the future ; for there is perhaps no science in which the observation of nature is not the grand foundation of all greatness and all excellence; because, indeed, in nature, as in a storehouse, we find treasured up the perfections of an omniscient and unerring Deity. The discovery of the principles of specific gravity by Archimedes—musical mathematics by Pythagoras, the pendulum by Galileo, and terrestrial gravitation by Newton ; all of these (and many more might be accumulated) are derived from the observation of the commonest phenomena—the bath, the blacksmith's anvil, a swinging cord, or a falling apple—while from them have been derived laws from the constitution of a universe to the arrangement of the most plodding machine. Teaching the students likewise, as Professor Daniell proposes, to reason on the phenomena presented to them, affords them a perpetual and available resource in all difficulties ; and one, than which nothing could be more appropriate to the mental habits of an engineer. It is to be regretted indeed that in too many cases it is thought sufficient to cram a youth with a quantity of facts, and leave him to digest and apply them in what manner he can, as if man were supplied with a whole stock of logic from nature.

The other courses are also marked by the same happy desire to obtain the most effective ends by the application of the soundest principles, and they cannot fail to promote the results they so zealously attempt. In the program to the course on Geometrical Drawing, where, under most circumstances we should be the last to expect to find such an admission, Professor Bradley truly observes, that considerable facility in the power of drawing by eye, with precision and freedom, is requisite to constitute a good draughtsman, and is to be attained by constant practice in sketching objects of any kind from nature. It seems however to be thought generally, both by architects and engineers, that to stick a rule and compasses in a boy's hand is quite enough to qualify him, although, independently of the artificial training which is thus effected, no attention is paid to the fact that the human eye is the most delicate instrument in nature. Professor Wheatstone takes up the subject of experimental philosophy, and it can be believed, by those who know him, with what practicability and good effect. Professor Tennant lays out an admirable course on Geological Mineralogy ; and indeed the whole arrangements are admirably calculated to effect the objects proposed on the institution of the class. We are happy indeed to see that there is no pretence to teach civil engineering, but that they wisely leave to those best qualified to teach those parts which are susceptible of being communicated by practical instruction, and only take on themselves such accessory portions as they can effect with credit to themselves and without injury to the pupils.

We may now come at last to the work before us, and we shall have no reason to regret any attention that we may pay to it, as it is quite worthy of the ability of the well-known author. The professors of King's College, it seems, have determined upon publishing a course of works on science, for popular instruction and they have acted very justly in confiding to Mr. Moseley the task of being their herald in the field ; and, as his introduction may be regarded as that to the whole course, we think that we cannot better express its objects than by favoring our readers with some extracts from this able production:—

The author has proposed to himself the development of that system of experimental facts and theoretical principles on which the whole superstructure of mechanical art may be considered to rest, and its introduction, under an available form, to the great business of practical education. To effect this object, and to reconcile, as far as it may be possible, the strictly scientific with the popular and elementary character of the undertaking, a new method has been sought, the nature of which is sufficiently indicated by its title—Illustrations of Mechanics. The work consists, in fact, of a series of illustrations of the science of mechanics, arranged in the order in which the parts of that science succeed each other, and connected by such explanations only, as may serve to carry the mind on from one principle to another, and enable it to embrace and combine the whole. Throughout, an attempt is made to give to the various illustrations an entirely elementary and practical character.

It is an idea which presents itself to the mind of every man who has children to educate and provide for, which is a constant subject of comment and discussion, and which prevails through all classes of society, that a portion of the school life of a boy ought to be devoted to the acquisition of those general principles of practical knowledge of which the whole business of his subsequent life is to form a special application ; that there ought, in fact, to be commenced by him at school a common apprenticeship to those great elements of knowledge, on which hang all the questions of interest which are to surround him in nature, and which are destined, under the form of practical science, to take an active share in the profession, trade, manufacture, or art, whatever it may be, which is hereafter to become the occupation of his life.

It is the object of this work, and of the series of which it forms part, to promote this great business of practical education, by supplying to the instructors of youth a system of elementary science, adapted to the ordinary forms of instruction. No one can doubt that the same capabilities in the scholar, united to the same zeal in the master, which now suffice to carry the elements of a classical education to the very refinements of philological criticism, would be equal to the task of instruction in the nomenclature of the physical sciences, their fundamental experiments, their elementary reasonings, and their chief practical results; nor can it be questioned that the ordinary intelligence of youth, and common diligence on the part of their teachers, would enable them to master the secrets of the more important of the arts, and the chief processes of the manufactures; and would place within their reach the elements of natural history, the general classification of the animal and vegetable kingdoms of nature, and their various ministries to the uses of man. These are elements of a knowledge which is of inestimable value in the affairs of life; and the interests of this great commercial and manufacturing community claim that they should no longer be left to find their way to the young mind (if, indeed, they reach it at all), rather as a relaxation of the graver business of education than as a part of it.

The illustrations of the mechanical properties of matter and the laws of force are drawn promiscuously and almost equally from art and nature. It is not by design that examples taken from these distinct sources thus intermingle, but simply because they suggest themselves as readily from the one source as the other—from nature as abundantly as from art. There is a relation between art and nature—a relation amounting to more than a resemblance;—a relation by which the eye of the practical man may be guided to that God who works with him in every operation of his skill, and mechanical art elevated from a position which is sometimes unjustly assigned to it among the elements of knowledge. It is from this relation between the Author of nature and the being in whom the works of art have their origin that arise those relations, infinitely remote, but distinct, between the things themselves, of which the evidence is every where around us. These are necessary relations: it is not that the works of art are made by any purpose or intention in the resemblance of those of nature, or that there is any unseen influence of nature itself upon art; the primary relation is in the causes whence these severally proceed. Thus it is possible, that in the infinities of nature, every thing in art may find its type; this is not, however, necessarily the case, since the causes are infinitely removed, since, moreover, in their operation, these causes are independent, and since nature operates upon materials which are not within the resources of art. How full of pride is the thought, that in every exercise of human skill, in each ingenious adaptation, and in each complicated contrivance and combination of art, there is included the exercise of a faculty which is akin to the wisdom manifested in creation! And how full of humility is the comparison which, placing the most ingenious and the most perfect of the efforts of human skill by the side of one of the simplest of the works of nature, shows us but one or two rude steps of approach to it.

The arrangement of the work will perhaps be better understood by leaving it in the author's own words, so that we have selected for our readers the following detail of it:—

Matter is composed of elements, which are inappreciably and infinitely minute; and yet it is within the infinitely minute spaces which separate these elements that the greater number of the forces known to us have their only sensible action. These, including compressibility, extensibility, elasticity, strength, capillary attraction and adhesion, receive their illustration in the first three chapters of the following work. The fourth takes up the Science of Equilibrium, or Statics; applies in numerous examples the fundamental principles of that science, the parallelogram of forces, and the equality of moments; then passes to the question of stability, and to the conditions of the resistance of a surface; traces the operation of each of the mechanical powers under the influence of friction; and embraces the question of the stability of edifices, piers, walls, arches, and domes.

The fifth chapter enters upon the Science of Dynamics. Numerous familiar illustrations establish the permanence of the force which accompanies motion; show how it may be measured; where in a moving body it may be supposed to be collected; exhibit the important mechanical properties of the centres of spontaneous rotation, percussion, and gyration; the nature of centrifugal force; and the properties of the principal axes of a body's rotation; the accumulation and destruction of motion in a moving body, and the laws of gravitation.

The last chapter of the work opens with a series of illustrations, the object of which is to make intelligible, under its most general form, the principle of virtual velocities, and to protect practical men against the errors into which, in the application of this universal principle of mechanics, they are peculiarly liable to fall: it terminates with various illustrations of those general principles which govern the reception, transmission, and application of power by machinery, the measure of dynamical action, and the numerical efficiencies of different agents—principles which receive their final application in an estimate of the dynamical action on the moving and working points of a steam engine.

The Appendix to the work contains a detailed account of the experiments of Messrs. Hodgkinson and Fairbairn upon the mechanical properties of hot and cold blast iron: and an extensive series of tables referred to in the body of the work, and including, 1. Tables of the strength of materials; 2. Tables of the weights of cubic feet of different kinds of materials; 3. Tables of the thrusts of semi-circular arches under various circumstances of loading, and of the positions of their points of rupture; 4. Tables of co-efficients of friction, and of limiting angles of resistance, compiled and calculated from the recent experiments of M. Morin. The results of these admirable experiments, made at the expense of the French government, are here, for the first time, published in this country.

A Dictionary of Arts, Manufactures, and Mines. By Andrew Ure, M.D. London. Longman and Co.

We have now come to a final notice of this work, and we cannot dismiss it without presenting to our readers a few more extracts. The following is from the article on slate, and gives a brief sketch of the localities in which that material is found:—

Clay-slate.—This substance is closely connected with mica; so that uninterrupted transitions may be found between these two rocks in many mountain chains. It is a simple schistose mass, of a bluish-gray or grayish-black colour, of various shades, and a shining, somewhat pearly internal lustre on the faces, but of a dead colour in the cross fracture.

Clay-slate is extensively distributed in Great Britain. It skirts the Highlands of Scotland, from Lochlomond by Callender, Comrie, and Dunkeld; resting on, and gradually passing into mica-slate throughout the whole of that territory. Roofing-slate occurs, on the western side of England, in the counties of Cornwall and Devon; in various parts of North Wales and Anglesea; in the north-east parts of Yorkshire, near Ingleton, and in Swaledale; as also in the counties of Cumberland and Westmoreland. It is likewise met with in the county of Wicklow and other mountainous districts of Ireland.

All the best beds of roofing-slate improve in quality as they lie deeper under the surface; near to which, indeed, they have little value.

A good roofing-slate should split readily into thin even laminæ; it should not be absorbent of water either on its face or endwise, a property evinced by its not increasing perceptibly in weight after immersion in water; and it should be sound, compact, and not apt to disintegrate in the air. The slate raised at Eisdale, on the west coast of Argyllshire, is very durable.

Cleaving and dressing of the slates.—The splitter begins by dividing the block, cut lengthwise, to a proper size, which he rests on end, and steadies between his knees. He uses a mallet and a chisel, which he introduces into the stone in a direction parallel to the *folia*. By this means he reduces it into several manageable pieces, and he gives to each the requisite length, by cutting cross grooves on the flat face, and then striking the slab with the chisel. It is afterwards split into thinner sections, by finer chisels dexterously applied to the edges. The slate is then dressed to the proper shape, by being laid on a block of wood, and having its projecting parts at the ends and sides cut off with a species of hatchet or chopping-knife. It deserves to be noticed, that blocks of slate may lose their property of divisibility into thin laminæ. This happens from long exposure to the air, after they have been quarried. The workmen say, then, that they have lost their waters. For this reason, the number of splitters ought to be always proportioned to the number of block-hewers. Frost renders the blocks more fissile; but a supervening thaw renders them quite refractory. A new frost restores the faculty of splitting, though not to the same degree; and the workmen therefore avail themselves of it without delay. A succession of frosts and thaws renders the quarried blocks quite intractable.

This account is, however, rather meagre, as it totally omits one of the great districts, that of Furness, in Lancashire, which supplies slate of excellent quality, and much used in that neighbourhood. There is no distinction made between the several varieties, and the manner in which the locality is determined by the colouring of the slate, the slates of Cornwall and Westmoreland differing totally in respect to colour. The application of slate also as a paving material, and its applicability in solemn decoration, as for tombstones, library chimney-pieces, slabs, &c., are not alluded to. The ensuing account of the manufacture of stained glass is rather more chemical than practical:—

Stained Glass.—When certain metallic oxides or chlorides, ground up with proper fluxes, are painted upon glass, their colours fuse into its surface at a moderate heat, and make durable pictures, which are frequently employed in ornamenting the windows of churches as well as of other public and private buildings. The colours of stained glass are all transparent, and are therefore to be viewed only by transmitted light. Many metallic pigments, which afford a fine effect when applied cold on canvas or paper, are so changed by vitreous fusion as to be quite inapplicable to painting in stained glass.

The glass proper for receiving these vitrifying pigments, should be colourless, uniform, and difficult of fusion; for which reason crown glass, made with little alkali, or with kelp, is preferred. When the design is too large to be contained on a single pane, several are fitted together, and fixed in a bed of soft cement while painting, and then taken asunder to be separately subjected to the fire. In arranging the glass pieces, care must be taken to distribute the joinings so that the lead frame-work may interfere as little as possible with the effect.

A design must be drawn upon paper, and placed beneath the plate of glass; though the artist cannot regulate his tints directly by his pallet, but by specimens of the colours producible from his pallet pigments after they are fired. The upper side of the glass being sponged over with gum-water, affords, when dry, a surface proper for receiving the colours, without the risk of their running irregularly, as they would be apt to do, on the slippery glass. The artist first draws on the plate with a fine pencil, all the traces which mark the great outlines and shades of the figures. This is usually done in black, or, at least, some strong colour, such as brown, blue, green, or red. In laying on these, the painter is guided by the same principles as the engraver, when he produces the effect of light and shade by dots, lines, or hatches; and he employs that colour to produce the shades, which will harmonize best with the colour which is to be afterwards applied; but for the deeper shades, black is in general used. When this is finished, the whole picture will be represented in lines or hatches similar to an engraving finished up to the highest effect possible; and afterwards, when it is dry, the vitrifying colours are laid on by means of larger hair pencils; their selection being regulated by the burnt specimen tints. When he finds it necessary to lay two colours adjoining, which are apt to run together in the kiln, he must apply one of them to the back of the glass. But the few principal colours to be presently mentioned, are all fast colours, which do not run except the yellow, which must therefore be laid on the opposite side. After colouring, the artist proceeds to bring out the lighter effects by taking off the colour in the proper place, with a goose quill cut like a pen without a slit. By working this upon the glass, he removes the colour from the parts where the lights should be the strongest; such as the hair, eyes, the reflection of bright surfaces and light parts of draperies. The blank pen may be employed either to make the lights by lines, or hatches and dots, as is most suitable to the subject.

By the metallic preparations now laid upon it, the glass is made ready for being fired, in order to fix and bring out the proper colours. The furnace or kiln best adapted for this purpose, is similar to that used by enamellers.—[See Enamel, and the *Glaze-kiln*, under Pottery.] It consists of a muffle or arch of fire-clay or pottery, so set over a fireplace, and so surrounded by flues, as to receive a very considerable heat within, in the most equable and regular manner; otherwise some parts of the glass will be melted; while, on others, the superficial film of colours will remain unvitrified. The mouth of the muffle, and the entry for introducing fuel to the fire, should be on opposite sides, to prevent as much as possible the admission of dust into the muffle, whose mouth should be closed with double folding-doors of iron, furnished with small peep-holes, to allow the artist to watch the progress of the staining, and to withdraw small trial slips of glass, painted with the principal tints used in the picture.

The muffle must be made of very refractory fire-clay, flat at its bottom, and only 5 or 6 inches high, with such an arched top as may make the roof strong, and so close on all sides as to exclude entirely the smoke and flame. On the bottom of the muffle a smooth bed of sifted lime, freed from water, about half an inch thick, must be prepared for receiving the pane of glass. Sometimes several plates of glass are laid over each other with a layer of dry pulverulent lime between each. The fire is now lighted, and most gradually raised, lest the glass should be broken; and after it has attained to its full heat, it must be kept up for 3 or 4 hours, more or less, according to the indications of the trial slips; the yellow colour being principally watched, as it is found to be the best criterion of the state of the others. When the colours are properly burnt in, the fire is suffered to die away, so as to anneal the glass.

The description of an Artesian well, at Mortlake, is interesting, but it appears to us that it should be received with some caution as an example, for it seems by no means satisfactory as a general rule that water would be found in the soft chalk.

Artesian Wells.—The following account of a successful operation of this kind, lately performed at Mortlake, in Surrey, deserves to be recorded. The spot at which this undertaking was begun, is within 100 feet of the Thames. In the first instance, an auger, seven inches in diameter, was used in penetrating 20 feet of superficial detritus, and 200 feet of London clay. An iron tube, 8 inches in diameter, was then driven into the opening, to dam out the land-springs and the percolation from the river. A 4-inch auger was next introduced through the iron tube, and the boring was continued until, the London clay having been perforated to the depth of 240 feet, the sands of the plastic clay were reached, and water of the softest and purest nature was obtained; but the supply was not sufficient, and it did not reach the surface. The work was proceeded with accordingly; and after 55 feet of alternating beds of sand and clay had been penetrated, the chalk was touched upon. A second tube, 4½ inches in diameter, was then driven into the chalk, to stop out the water of the plastic sands; and through this tube an auger, 3½ inches in diameter, was introduced, and worked down through 35 feet of hard chalk, abounding with flints. To this succeeded a bed of soft chalk, into which the instrument suddenly penetrated to the depth of 15 feet. On the auger being withdrawn, water gradually rose to the surface and overflowed. The expense of the work did not exceed 300*l*. The general summary of the strata penetrated is as follows:—Gravel, 20 feet; London clay, 250; plastic sands and clays, 55; hard chalk with flints, 35; soft chalk, 15;= 375 feet.

We cannot leave this work without again expressing our opinion of its general utility. Executed as it is under the guidance of one man, it must necessarily partake of the defects of his limited experience; but in all those departments which may be considered Dr. Ure's own, the matter possesses more than average merit. The chemical portions are essentially good, but in many of the technical parts a want of acquaintance with the latest processes is observable. In our own branches we have before remarked on this deficiency, and of course the same observation extends to many arts and manufactures beyond the limits of our critical sphere. Thus, the article on button making is extremely erroneous, and in that on black dyes we find no mention of the French processes, although it is notorious that there is a marked difference between their method and our own. Generally we think that the Doctor might have paid more attention to the French and German Encyclopedias of Trades, from which many interesting illustrations might have been obtained. As the first work of its class in the field, however, it possesses merits peculiarly its own, and a right of exemption from blame, where one has done so well; and it may be consulted usefully by all, as containing a mass of information nowhere else to be found.

British Critic and Theological Review.—No. 50.

Do not let our readers be startled by this title, or imagine that we are going to *edify* them by a theological disquisition; no, we merely call their attention to the last number, because it contains two architectural papers, which might, but for our doing so, quite escape their notice. One of them is entitled "Interior Decorations of English Churches," the other is a review of "Pugin's Contrasts;" and it is to this latter that we shall confine our remarks, not having as yet perused the first one, except in a very hurried manner. Whether Welby Pugin will think proper to bring out a pamphlet in reply to this article, as he did in answer to—or, rather, by way of attempt at answering—certain Strictures upon his book in *Fraser*, remains to be seen. But the reviewer certainly does not spare *Mrs. Candour* Pugin, as he has been styled in some other publication; the most he does is to throw him a sop by praising his drawings, which, he says, "exhibit an exquisite taste, and confirm us in our previous opinion, that Mr. Pugin is the first Gothic architect of the age." It is difficult to make out whether this be intended as ironical or not: yet, if it be actually intended as praise, it puzzles us still more, for coarser scratches than are the plates to the "contrasts" can hardly be imagined; while, as every one at all acquainted with the style must admit, no little of the character and charm of Gothic architecture depends upon the beautiful forms and execution of the details. It is, besides, chiefly with respect to detail and decoration —in which he is said to be unsparing—that Mr. P. has much pretension to the name of architect;—at least, we have not seen any designs, or heard of his having ever done any thing, except in mere fittings up. We do not say that he is capable of achieving nothing more, but merely mean that there is no evidence to show that he is fairly entitled to the praise of being "the first Gothic architect of the age," since, had he executed any thing which would sanction it, it would hardly remain a secret; unless Mr. Pugin's buildings are to be classed among those things whose fate it is "to be," as some one has observed, "exceedingly famous, yet little known." A little further on he gets another *sop*, where it is said, "Homer was blind, and Mr. Pugin cannot argue;"—it might have been added, nor can he spell. The reviewer has pointed out his peculiar mode of spelling Windsor on one of his plates, and in another he has converted Mr. Brayley into Mr. Bragley, which howe er may pass as one of those unaccountable intentional blunders people are apt to fall into. The principle upon which Mr. P. planned his "Contrasts" is well exposed, and shown to be one by which any person may make good any argument, merely by bringing forward all that makes for it and taking no notice of the ugly facts that make against it.

"Of the remaining 'Contrasts,'" says the reviewer, "we will only ask whether it is fair to compare a common cast-iron pump with a handsome stone conduit, or Sir John Soane's house with the work of any sensible architect of any age or country?" That last remark touches us to the very quick, for it puts us quite out of conceit with the "house, No. 13, Lincoln's-inn Fields;" which, belonging as it does, or is fancied to do, to the public, is the house of every Englishman.

However, we will venture to prescribe the article to our readers, who may wash it down either with "*Vin. Port*," or "*Aq. pura*."

Penny Cyclopædia: Article, "London."

The 74th part of this publication deserves to be pointed out by us to our readers, as containing, under the head of "London," an able though brief architectural review of the principal buildings in the metropolis; accompanying which there is an excellent table of them, arranged chronologically in centuries, with the respective dates and architects' names, and further remarks on them in a separate column. Such an architectural synopsis is a quite novel and no less happy idea; and it is so exceedingly useful for reference, that we have no doubt the same plan will be henceforth adopted in other works. Such a table ought, in fact, invariably to accompany the *Guide Book* of any city, if merely to serve as an index, pointing out at a glance all the buildings most worthy of note, and the architects by whom they were erected.

The table we are now speaking of does not profess to be a complete list of all the public edifices in the metropolis, but merely of such as have pretension to rank as works of architecture; whereas in the other case, a great many would have been included which possess no architectural interest whatever. It is, as we have said, divided into centuries, beginning with the seventeenth; and of the seventy-three buildings mentioned in it, no fewer than fifty-three have been erected in the course of the last thirty years, or from 1808 to 1838; a tolerably striking proof how much more than at any former period has been done in our own time, especially if we further take into account street architecture and general improvements. As a specimen, we shall extract this table:—

TABLE OF PUBLIC BUILDINGS MOST WORTHY OF NOTICE FOR THEIR ARCHITECTURE.

	Date.	Architect.	Remarks.
Seventeenth Century.			
Whitehall Chapel	1619	Inigo Jones	Chiefly admirable as the finest specimen of pure Italian.
York Stairs	1626	Ditto	
St. Paul's, Covent Garden	1631	Ditto	Tuscan, distyle in antis.
Temple Bar	1670-2	Sir C. Wren	
The Monument	1671-7	Ditto	Fluted Doric column; total height, including pedestal, &c., 202 feet.
St. Stephen's, Walbrook	1672-9	Ditto	Exterior concealed by houses; interior over-praised; chiefly remarkable for its dome.
St. Paul's Cathedral, begun	1675	Ditto	Extreme length, 500 feet; height to top of cross, 360.
Eighteenth Century.			
St. Paul's finished	1710	J. James	Style Italo-Roman; exterior both magnificent and picturesque, though not faultless.
St. George's, Hanover-square	f. 1724	J. Gibbs	Portico hexastyle, Corinthian.
St. Martin's	1721-6	Ditto	Portico hexastyle, Corinthian; the general style bad.
St. George's, Bloomsbury	f. 1731	Hawksmoor	Ditto, ditto; Campanile excellent.
Mansion House	1739-53	Dance	
Westminster Bridge	1739-50	Labelye	Length 1066 feet.
Ironmongers' Hall	1748	Holden	Italian Ionic on basement.
Horse Guards	1751	W. Kent	
Blackfriars Bridge	1760-70	R. Mylne	Length 1000 feet.
Excise Office	1769	James Gandon	Plain in design, but of most commanding aspect.
Adelphi	1770	Adams	Admirable in design and character
Newgate	1770-82	Dance	Though poor in parts, a good example of Italian. River front 590 feet.
Somerset House	1776	Sir W. Chambers	East front handsome.
Clerkenwell Sessions House	1780	Rogers	Very picturesque in parts.
Bank	1789-1826	Sir J. Soane	Hexastyle loggia, Grecian Ionic, sculptured frieze and pediment.
India House	1799	R. Jupp	
Nineteenth Century.			
Covent-Garden Theatre	1808-9	Sir R. Smirke	Grecian Doric; tetrastyle portico.
Drury-Lane Theatre	1811-12	B. Wyatt	
Opera-House, altered	1818	Nash and Repton	
Bethlehem Hospital	1812-15	J. Lewis	Portico hexastyle, Ionic. Length 569 feet.
Waterloo Bridge	1811	J. Rennie	Length 1326 feet.
Mint	1811	Sir R. Smirke	Grecian Doric on a basement.
Custom House	1813	D. Laing	The Long Room and centre of the river front quite altered after the accident in 1826. Length 484 feet.
London Institution	1815-19	W. Brooks	
St. Pancras Church	1819-22	W. and H. W. Inwood	The finest copy of Athenian Ionic.
Post-Office	1823-9	Sir R. Smirke	Hexastyle, Ionic portico; extent of front 390 feet.
Hanover Chapel, Regent-street	1823-5	R. C. Cockerell	Tetrastyle Ionic portico.
British Museum (new buildings)		Sir R. Smirke	
Buckingham Palace	1825	Nash and Blore	
College of Physicians and Union Club-House	1825-7	Sir R. Smirke	Grecian Ionic.
Board of Trade	1824-6	Sir J. Soane	Roman Corinthian.
Colosseum	1824	D. Burton	Hexastyle, Grecian Doric portico attached to a polygon 130 feet diameter.
London Bridge	1825-31	J. Rennie	Length 920 feet.
St. Mark's, North Audley-street	1825-8	Gandy-Deering	Florid Grecian Ionic; façade small, but of rich design.
St. Katherine's Hospital	1826	Poynter	Chapel Gothic; the rest Old English Domestic.
Hall, Christ Church Hospital	1826	J. Shaw	Later Gothic.
Scotch Church, Regent-square	1827-8	W. Tite	Gothic.
St. George's Hospital	1827	W. Wilkins	Portico tetrastyle, with square pillars.
London University	1827-9	Ditto	Façade not completed; decastyle portico, and dome.
New Corn Exchange	1827-8	G. Smith	Grecian Doric, with pleasing originality of design.
St. Paul's School	1827	Ditto	Hexastyle, Tivoli Corinthian on a basement.
Law Institution, Chancery-lane	1827-9	L. Vulliamy	Grecian Ionic hexastyle.
Archway, Green Park	1828	D. Burton	
Fishmongers' Hall	1827-34	H. Roberts	Grecian Ionic.
Athenæum Club	1829	D. Burton	Its bas-relief frieze, the only specimen in London.
Goldsmiths' Hall	1829-35	P. Hardwick	Italian; magnificent, yet somewhat heavy, and basement poor.
Exeter Hall	1830-1	Gandy-Deering	Greco-Corinthian, distyle in antis.
St. Dunstan's in the West	1830-32	J. Shaw	Gothic; handsome Louvre tower.
York Column	1830-36	B. Wyatt	Total height, including statue, 137 feet 9 inches.
Lowther Arcade	1830	J. Turner	Greco-Italian, with pendentive domes.
Hungerford Market	1831-3	C. Fowler	
Travellers' Club	1831	C. Barry	Choice specimen of the best Italian style, particularly the design of garden front.
Charing-Cross Hospital	1830-1	D. Burton	
St. George's, Woburn-square	1832	L. Vulliamy	Gothic; handsome spire.
Westminster Hospital	1832	Inwoods	Modernized Gothic.
National Gallery	1832-7	W. Wilkins	Grecian; total extent of front 458 feet.
State-Paper Office, St. James's Park	1833	Sir J. Soane	One of his chastest productions. Style, Italian.
Pantheon Bazaar	1834	S. Smirke	
School for Indigent Blind	1834-7	J. Newman	Style Tudor, white brick and stone; central tower of rich design.
St. Olave's School	1835	J. Field	Style Elizabethan, red brick and stone.
College of Surgeons	1835-6	C. Barry	Italianized Grecian.
United University Club	1836-7	Sir R. and S. Smirke	Style a modified Italian; bas-relief panels.
St. James's Theatre	1836	S. Beazley	
Railway Terminus, Euston-square	1837-8	P. Hardwick	A Grecian Doric propylæum on an imposing scale.
London and Westminster Bank	1837-8	Cockerell and Tite	Style modified Italian; singular but pleasing.
Synagogue, Great St. Helen's	1837-8	J. Davies	Style Italian; interior rich and tasteful.
Reform Club	1838	C. Barry.	Italian.

2. *Lectures on Colour.* By Hyde Clarke, Esq.
3. *Transactions of the Society of Arts for* 1838.

The subject of light and colour is one of the most important which now engages the scientific world; and in consequence of the sensation created by photography, hardly a day elapses without some new or startling discovery. It is only, indeed, of late, and we hardly know if we may say unanimously, that a theory of light has been adopted which is at all satisfactory. Hypothesis and system, like the marshalling of an army, is the first step for the advancement of a science, and we may well wonder, after so many brilliant discoveries made by the greatest men, to find the science of light less advanced than chemistry and geology, which are things of yesterday. This has arisen primarily from the adoption of a bad system, which is tantamount to no system at all, or worse; for until recently, the corpuscular theory, or that which teaches the direct procession of light from the sun, ruled with all the weight which the name of its great patron, Newton, could give to it. Its supporters also forgot the principles of their master, the man who considered himself like a loiterer, picking up pebbles on the shores of the vast ocean of science, and blindly maintained the justice of his opinions, without any compunction that he too might err; and it seems, indeed, a principle derived from the weakness of human nature—that we must ever worship men, and not truth. This ridiculous calling ourselves of Paul and of Cephas was never perhaps carried to a more extraordinary length than when lately before the Ashmolean Society a defence of Newton's opinions was read, and it was endeavoured to be proved that he was a supporter of those principles which now have the predominance. A blind result of our wretched ignorance, that we cannot judge for ourselves, but must follow a leader, whom, if we had but judgment, we should know how to be guided by; but one error found out, rather than again be exposed to the consequences of our neglect, we dash our once-favoured idol on the ground. Another important cause which has doubtless contributed to the retardment of this science has been the circumstance that it has been courted primarily and almost exclusively by mathematicians; whereas, from its being the disposition of naturalists to observe, and of mathematicians to reason, the wholesome course of a science is to collect facts, in the first instance, and to arrange them afterwards. In good truth, optics has been studied as by a foreigner, who trusting to his memory rather than his knowledge, speaks English from a vocabulary, instead of with the freedom of common life.

It is doubtless from this waut of progress of the science, and from its not having attained a popular and practical form, that we must attribute that continued neglect of colour in decoration, which was first caused by the puritanical destruction of the arts. Even the commonest principles of contrast and harmony, which would not take an hour's teaching in a common school, are not diffused, and it cannot be astonishing if we suffer from a universal ignorance in our houses and our manufactures. The Egyptians, however, possessed by observation what neither science nor observation has taught us; and although they used only the simplest colours, yet the manner in which they were applied in their temples and in their tombs may justly excite our admiration. Although so restricted in the number of their colours, the Egyptians produced many bold effects, when they had comparatively no media to soften down their great masses. Harmony is the general characteristic of Greek decoration, and, by the employment of weak tints, they managed to attain great delicacy of expression. Blue, from its coolness, they used very much in masses, and it greatly aided the purity of their designs. They were very happy, too, in the management of black and its contrasts, yellow and white, and used them much more aptly in the decoration of objects than we do. They also made colour a handmaid to the sculptural arts, as may yet be seen on some of the statues in the British Museum, and in other places; and they even mixed different coloured marbles for such objects, as the leopard with black marble spots in the Museum at Naples. They used painting also very extensively on the exterior of their edifices, and with the most happy effect. With regard to the manner in which the Moors used this delightful vehicle of harmony, nothing can be more attractive than the specimens of their internal decoration with which we are acquainted. We are happy to see the increasing use of fresco, but we want more public examples, such as may animate the public taste which already exists. The painted ceilings at Greenwich and Hampton Court never fail to attract the attention of the public, and there can be no doubt that they would fully appreciate whatever might be done. No places can be more appropriate for this improvement than the public museums, and however wretched may be their condition we still feel more comfortable in the old rooms at the British Museum than in the barren walls of the new. The walls indeed should be a running commentary on the contents, like the Glyptotheca and the Pinacotheca, or like in the Palace of the Conservatori, in the Capitol at Rome, where the Roman statuary is accompanied by friezes illustrative of the history of the republic. It cannot be said that this would detract from the contents of the Museum, as we have the example of the Louvre, where no one turns away from the immortal works to the gorgeous ceiling. By this employment of painters and sculptors an impulsive force would be given to architecture, and architects would more than regain what they might expend in the first instance. The fine arts, indeed are not to be promoted like the livers of French geese, by an artifical plethora of one member, nor are they like a tree where the remaining limbs profit by the pruning down of the rest, but they must be cultivated in common, and to neglect any individual branches is to strike at the roots and destroy the nourishment of the rest.

The operations of colour are determined by strict mathematical laws, and colours possess, if it may be so termed, an atomical constitution. Newton, it may be remembered, determined by the prismatic experiment that there were seven simple colours, because he could not decompound any of them; but practical artists had long rejected this doctrine, from being able to produce the whole from three. Before the determination of this question Mr. Hay had performed some very ingenious experiments, which he relates, by which he mixed the yellow and red rays and produced orange, the yellow and blue green, and so on through the others; thus producing by synthesis what Newton could not effect by analysis. The subject has now been determined by Sir David Brewster, and it is now taught that light is composed of only three simple colours, yellow, red, and blue; that if these be reflected in their due proportion, which is in an active state, white is produced; if absorbed, which is a passive state, black is the result.

The powers of these, as determined by Field, are yellow, three; red, five; and blue, eight. Mr. Hyde Clarke has given an analysis of the prismatic spectrum, by which much the same result is produced. Arranging the simple and compound colours under the heads of yellow, red, and blue, and dividing them by twenty, the following is the result:—

	Yellow.	Red.	Blue.
Simple . . .	48	45	60
Orange	10	17	
Green	16	0	44
Indigo, &c. . .	0	54	66
Divide by 20	74	116	170
	3	5	8

These three simple colours, by their combination, form the secondary, red and yellow, orange, 8; yellow and blue, green, 11; red and blue, purple, 13. The simple colours are softened down by the secondaries which they form in combination with the other two colours, yellow by orange and green; red by orange and purple; blue by green and purple; and they are contrasted by a combination of the two colours, necessary to make up the triad, which forms the compliment of the colour with 16; as yellow 3 by green 13, 16; red 5 by green 11, 16; and blue 8 by orange 8, 16. The same principle prevails in nature in many extraordinary phenomena, as, for instance, in that discovered by Buffon, when if you look steadily for some time on a spot of yellow colour, placed on a black or white surface, it will appear surrounded by a purple tinge; and so in the phenomena of polarised light also, if the ordinary ray be red or blue, the extraordinary ray will be green or orange. Sir John Robison related before the French institute a remarkable instance of this contrasting power in nature: a surgeon of his acquaintance bled a patient in a porcelain basin having green flowers at the bottom, and some time afterwards it was observed that on the surface of the blood were formed red flowers corresponding to the green; and this experiment was repeated several times to ensure its not being an accident. In music the same thing occurs, where there are three simple notes, C E and G, and if any one of them be sounded it will be accompanied by the other two as the harmonics; this may be perceived in the sound of a bell in succession, and in an accompaniment on the string of a violincello. From the combination of the secondaries proceed the testiaries, orange and green form citron, 19; orange and purple, russet, 21; and green and purple, olive, 24. These act with regard to the secondaries as the secondaries do to the primaries, and their neutralising power is 32: thus orange, 8, is contrasted by olive, 24; green, 11, by russet, 21; and purple, 13, by citron, 19. Besides their perfect intensity, all the colours can be raised towards darkness, which is called shade, and lowered towards light, called tint; and the compound colours have besides the variation of hue, by which is meant a greater admixture of any of the composing colours—thus orange may be made from the yellowest to the reddent. In a composition a strict equality must be preserved in these variations of shade, tint, and hue.
